The root of the common *madder* cultivated for the ufe of the dyers, is an excellent aperient and diuretic. It is prefcribed with great fuccefs in obftructions of the liver and fpleen, in fuppreffions of the menfes and urine, and in dropfies, jaundices, and cachexies. It is alfo recommended as a vulnerary, and faid to be peculiarly excellent in the diffolving coagulated blood. The dyers prepare a red colour with it, and ufe it alfo as a firft tint for feveral others.

RUBIA *icterita*, a term ufed by Paracelfus and his followers for the erifipelas.

RUBICAN, in the manege. A horfe is faid to be of a *rubican* colour, that is a bay, forrel, or black, with a light grey or white upon the flanks; but fo that this grey or white is not predominant there.

RUBICILLA *americana*, in zoology, a name given by Mr. Ray to the *guiratirica*, a Brafilian bird, of the bullfinch kind, very beautifully variegated with red, black and grey. See the article GUIRATIRICA.

RUBICULUS, in ichthyology, a name given by Figulus and fome others to that fpecies of fifh which we call the *roach*. It is of the cyprinus kind, and is diftinguifhed by Artedi under the name of the red-eyed cyprinus, with the tail and belly fins red. See the article CYPRINUS.

RUBIGO, (*Cycl.*) in hufbandry, is the name by which the antients expreffed what we call the *blight* in corn, &c. they gave it this name from the refemblance of the colour of the blighted ftalks to rufty iron.

They generally thought that it came from heaven, being ignorant of its true caufe, which is want of nourifhment in the earth. Virgil gives this up as an incurable diftemper, and tells the farmer, that if his corn is blighted he muft live upon acorns, not fuppofing that any remedy could be devifed for fuch a diftemper.

Palladius gives many receipts to cure the *blight*, and other diftemperatures of corn that come from above, as they imagined at that time. The chief efficacy of thefe feems to confift in certain fecret fympathies and antipathies, to fright the clouds away with. The world will eafily judge how likely fuch means as thefe were to have fuccefs.

The antient farmers generally ufed prayers, fupplications, and facrifices to their gods on this occafion; and if thefe did not fucceed, they proceeded to blafphemy and threatenings, and brandifhed bloody axes againft the fky, as a token to their gods to defift from plaguing them, or elfe to expect no quarter. They ufed to hang up in their fields and gardens, on thefe occafions, pieces of red cloth, and the feathers and heart of an owl, as a way to fright the clouds from coming over thofe places. Thefe people in general having no true knowledge of the theory of hufbandry, had recourfe to magic, and ufed what they thought fpells and enchantments on all occafions. Cato, Varro, and even Columella, are full of thefe ridiculous devices. A better knowledge in the real nature of hufbandry, has taught us to underftand this matter in a very different manner, and to apply more efficacious remedies to it. *Tull's* Horfehoing Hufbandry, p. 68. See BLIGHT.

RUBINUS, the *ruby*, in natural hiftory. See RUBY.

RUBRICA, in natural hiftory, a red earth ufed for marking, and in painting. There are two kinds of it, a harder and a fofter.

The firft, or harder kind, is but little in ufe, except among the turners in wood, as it does not mark fo eafily, requiring to be firft wetted, and then preffed hard upon the fubftance to be marked. This is dug in Lincolnfhire, Hampfhire, and Suffex; and is a hard and dry earth, of a fomewhat pale red, like the common pale red bricks, and is of a very regular and clofe texture, and always compofed of a number of thin lamina, lying clofely and evenly on one another. It is of a rough uneven furface, adheres firmly to the tongue, is not eafily broken between the fingers, and ftains the hands a little; it is of a very aftringent tafte, and melts pretty readily in the mouth. It is very readily diffufible in water, mouldering to powder, foon after being thrown into it, and makes no effervefcence with acids.

The fecond or fofter kind is very common, and put to a number of different ufes. It makes fimply a very good pale red for the painters, and is very ferviceable to them in their mixed colours. It is in conftant ufe in many parts of the kingdom for the marking of fheep; and when wafhed and feparated from its fandy particles, is, by fome of our modern druggifts, fold under the name of bole armenic.

It is found in many parts of the world; the beft in England is that from feveral parts of Derbyfhire, from whence the colour-fhops and druggifts of London are fupplied; many of the latter thinking this a fhorter method than the common one of our bole armenic makers, of preparing it from a mixture of tobacco pipe clay, and the red ochre called Spanifh brown. See BOLE and BOLUS.

This foft, or common *ruddle*, is a loofe ponderous earth, of a lax texture, and very friable; and of a pale, but tolerably bright red, of a fomewhat fmooth and gloffy furface, foft to the touch, adhering firmly to the tongue, eafily broken between the fingers, and ftaining the hands. It is of a rough auftere tafte, very readily breaks, and falls to powder in water, and makes no effervefcence with aqua fortis. *Hill's* Hift. of Foff. p. 48.

RUBUS, the *blackberry bufh*, in botany, the name of a genus of plants, the characters of which are thefe. The flower is of the rofaceous kind, being compofed of feveral petals, arranged in a circular form on a cup, from the middle of which there arifes a piftil, furrounded with a great number of ftamina; this finally becomes a fruit of a globular form; compofed, as it were, of a number of fmall berries full of juice; thefe are affixed to a placenta, and contain oblong feeds. See Tab. 1. of Botany, Clafs 21.

The fpecies of *rubus* enumerated by Mr. Tournefort are thefe. 1. The common *blackberry bufh* with black fruit. 2. The French white flowered *blackberry bufh*. 3. The *rubus* with double white flowers. 4. The Polifh *rubus* without prickles, and with a large black fruit. 5. The common *rubus* without prickles. 6. The prickly *rubus* with the leaves and flower both elegantly divided. 7. The prickly *rafpberry bufh*. 8. The fmooth *rafpberry bufh*. 9. The fweet fcented *rubus*. 10. The white *rafpberry*. 11. The creeping *rubus* with bluifh fruit. 12. The dwarf alpine *rubus*. 13. The dwarf marfh *rubus*. 14. The creeping trifoliate *rubus*, with foft hoary leaves and large blue fruit. 15. The fmall, erect, hoary, white flowered alpine *rubus*. 16. The trifoliate dwarf upright elegant *rubus*, with prickles like the rofe-bufh, and a fruit of the colour and tafte of the ftrawberry. *Tourn.* Inft. p. 614.

RUBUS, in ichthyology, a name given by Joannes Cuba, Albertus, and fome other writers, to the fpecies of *ray*, ufually called the *fkaite* or *flaire*. See RAJA.

RUBY, *rubinus*, (*Cycl.*) in natural hiftory, a gem, the diftinguifhing character of which is, that it is of a red colour with an admixture of purple.

The *ruby*, in its moft perfect ftate, is a gem of very great beauty, and of equal value. It is often found perfectly pure, and free from all fpots or blemifhes; but it is much more frequently debafed by them, and greatly brought down in its value, efpecially in the larger fpecimens. It is of very great hardnefs equal to that of the fapphire, and fecond only to the diamond. It is various in fize, but is lefs fubject to variations in its fhape than moft of the other gems. It is moft frequently found very fmall; its common fize being that of the heads of the larger forts of pins; and when of this fize it is very cheap; but it is alfo found of four, fix, and ten carrats; and fometimes, though but very rarely, up to twenty, thirty, or forty; nay, we have accounts of fome of more than an hundred. It is never found of an angular or cryftalliform fhape, but always of a pebble like figure, often roundifh, fometimes oblong, and much larger at one end than the other, and in fome fort refembling a pear, and is ufually more or lefs flatted on one fide.

It is commonly fo naturally bright and pure on the furface as to need no polifhing; and is worn in rings, and in the crowns of princes, in its rough or native ftate. Its colour is red in very different degrees, from the deepeft garnet colour to that of the paleft red diamond, but it ever has with the red more or lefs of a purplifh tinge: this is very plainly diftinguifhed in the deeper coloured fpecimens, but in the pale ones is gradually lefs and lefs to be diftinguifhed in proportion to their degree of colour. Thefe are the diftinguifhing characters of the *ruby*, and by thefe it is eafily known from the garnet, carbuncle, and other red gems.

Our jewellers are very nice, though not perfectly determinate in their diftinctions; knowing this gem, in its different degrees of colour, under three names; the firft is fimply the *ruby*: this is the name they give it in its moft perfect and ftrongeft coloured ftate.

The fecond is the *fpinal ruby*. Under this name they know thofe *rubies*, which are of a fomewhat lefs deep and greatly lefs vivid colour, than what they call the true *ruby*, or fimply the *ruby*.

The third is the *balafs ruby*, a name derived from Balakeia, the

the name of a country where the paler *rubies* are principally found. Under this name they exprefs a pale, yet very bright *ruby*, with a fmaller admixture of the purple tinge than in the deeper coloured one, and fomething refembling the colour of the damafk rofe. This is of confiderable value, but lefs than the deeper, or as they call it the true *ruby*.

Befide thefe, they know alfo two other ftones, under the general name *rubies*, calling them the *rock ruby* and the *rubacelle*. But thefe are not truly of the *ruby* kind; the firft being a very beautiful fpecies of garnet, and having a tinge of blue with its red; and the other a hyacinth, having a manifeft caft of yellow.

We have the true *rubies* only from the Eaft Indies. In Europe there are not unfrequently found cryftals tinged to the true colour of the *ruby*, but thefe ever want its luftre and hardnefs. In the Eaft Indies, the true *rubies* are often found almoft colourlefs, and not unfrequently variegated with fpots or ftains of a pure blue, evidently the fame with that of the fapphire. Doubtlefs alfo the *ruby* is fometimes found like the other gems, wholly deftitute of colour; but in this cafe, as the hardnefs of the ftone is the only thing that proves it to be of the gem clafs; both this, and all the other colourlefs fpecimens of the gems, are confounded under the name of the colourlefs fapphire; or, as our jewellers chufe to fpeak it, the white fapphire. *Hill*'s Hift. of Foff. p. 590. feq.

Arfenical RUBY, *rubinus arfenicalis*, in chemiftry, a name given to a fublimation of a mixture of arfenic and common fulphur. Thefe two bodies mixed together in different proportions afford very different appearances. If arfenic, mixed with one tenth part of its weight of fulphur, be thrown into a crucible red hot upon the fire, and covered immediately with a tile, and finally poured out after two minutes fufion, it becomes a folid brittle mafs of a very pale yellow. If arfenic be melted in the fame manner, with a fifth part of fulphur, the mafs when cold will be of a red colour: and finally, if arfenic and fulphur be melted or fublimed together, in equal quantities, the product is a beautiful red tranfparent mafs, called *rubinus arfenicalis*.

Counterfeit RUBY. The way to give the true fine red of the *ruby*, with a fair tranfparence, to glaffes, is as follows. Calcine, in earthen veffels, gold diffolved in aqua regis till it become a red powder. The operation will require many days in a hot furnace; when the powder is of a proper colour, take it out; and when it is to be ufed, melt the fineft cryftal glafs, and purify it by often cafting it into water; finally add, by fmall quantities, enough of this red powder, to give it the true colour of a *ruby*, with an elegant and perfect tranfparence. *Neri*'s Art of Glafs, p. 192.

RUDD, in ichthyology, a name given by the Englifh to a fifh of the cyprinus kind; it is called *orfus* and *rutilus latus*, or the *broad roach* by authors, and in fome parts of England the *finfcale*. See ORFUS, RUTILUS and CYPRINUS.

RUDDER (*Cycl.*)—RUDDER-*irons*, in a fhip, are the cheeks of that iron, whereof the pintle is part, which is faftened and nailed down about the rake of the *rudder*.

RUDDER-*rope*, in a fhip. See ROPE, *Cycl.*

RUDDLE, *rubrica*, in natural hiftory. See RUBRICA.

RUDDOCK, in zoology, an Englifh name for the *rubecula*, more commonly known by the name of the *red breaft*, or *robin red breaft*. *Ray*'s Ornitholog. p. 160. See the article RUBECULA.

RUDMAS *day*, in our old writers, the feaft of the *holy crofs*. There are two of thofe feafts, one on the third of May, being the invention of the *crofs*; and the other the fourteenth of September, called *holy rood-day*, and is the exaltation of the crofs. *Blount*.

The word is compounded of the Saxon *rode*, i. e. *crux*, and *mafs-day*, i. e. feaft-day.

RUE, *ruta*, in botany, &c. See the article RUTA.

We have feveral forts of *rue* in the gardens of the curious, but the common kind only is propagated for medicinal ufe. All the kinds may be propagated, either by cuttings in the manner of rofemary, or elfe by feeds. Thefe fhould be fown in the fpring on a bed of light earth; and when the young plants come up, they fhould be removed at about two inches high to the places where they are to remain. *Miller*'s Gardners Dict.

Goats RUE, in medicine. See GALEGA.

Wild RUE. See the article HARMALA.

RUELLIA, in botany, the name of a genus of plants, defcribed by Linnæus, Plumier, and others, the characters of which are thefe. The cup is compofed of one leaf, and is divided into five erect narrow fegments. The flower confifts of one petal, the tube is of the length of the cup; the neck broad and inclined, and the verge divided into five open fegments. Thefe are all obtufe at the points, and the two upper ones are longer than the reft, and are turned a little backwards. The ftamina are four filaments placed in the wide part of the tube in pairs. The germen of the piftil is roundifh, the ftyle is flender, and of the length of the ftamina; and the ftigma is bifid and acute, and the lower fegment of it is rolled back. The fruit is a cylindric capfule rounded at each end; it is of the length of the cup, compofed of two valves and femibilocular: this contains fome roundifh but compreffed feeds. *Linnæi* Gen. Pl. p. 298. *Plumier* Gen. 2. *Dillen*. Hort. Elth. 248, 249.

RUFFE, in zoology, the Englifh name of the *cernua* or fmall gilded pearch, a fifh common in our rivers, and much refembling the pearch in figure. *Ray*'s Ichthyol. p. 334. See the article CERNUA.

The *ruffe* is called by the generality of authors *cernua fluviatilis*; and by fome *charus acerina* and *afpredo*. It is called by Johnfon and Charleton alfo *fcrollus*. Willughby, as well as thefe authors, has mentioned the *fcrollus* as another fpecies of fifh; but it is proved, by obfervation, that they are evidently the fame fpecies. Artedi makes this fifh a pearch, or *perca*; and accurately diftinguifhes it from the other fifh of that genus by the name of the pearch, with only one fin on the back, and with a cavernous head. See the articles CERNUA and PERCA.

This fifh may be preferved alive in glafs jars with frefh water, and be made very tame. It muft be fed, for it cannot fubfift on the animalcula of river water as fmall dace can. See DACE and Phil. Tranf. N° 478. p. 25.

No fifh fhews the circulation of the blood in a finer manner than *ruffs*, whofe fins are exceeding tranfparent. Befides, it is a creature vaftly tenacious of life, and will live twenty or thirty minutes out of water, without receiving much damage. Phil. Tranf. l. c. p. 26.

RUFFE, in ornithology, the name of a male fpecies of bird, the female of which is called *reeve*, and the Latin name for which is *aves pugnax*, or the fighting bird.

It is about five ounces in weight; its head is of a greyifh brown with blackifh fpots, its neck is grey, and its back and fhoulders variegated with black, white, and brown. Its breaft and belly are white, and its throat of a greyifh white, and fomething mottled. Its wings are black and white. The females are fomewhat fmaller than the males, and they feldom fight. The males have a very remarkable circle of long feathers, furrounding their necks in the form of a *ruff*, worn antiently by ladies, and from this the bird has its name; the feathers of this are fometimes white, but more ufually black, yellow, grey, or of a very fhining blackifh blue; nor is the diverfity of colour peculiar to the feathers of the *ruff* alone; but the whole body of the bird is fo variable, in this refpect, that at fome feafons it is fcarce poffible to find any two of the males which are exactly of the fame colour; but about Midfummer, when they have newly moulted, they are all of the fame colours, and continue fo till toward the fucceeding fpring. The beak is ridged and triangular, and is blackifh, and the feet of a yellowifh red. They come over to us in vaft numbers in fpring, and remain the fummer, building in fome parts of Lincolnfhire, particularly in the fenny country about Crowland. When they firft come over there are many more males than females among them; but thefe are fo continually fighting, that their number foon decreafes below an equality. They are fed up after they are taken with bread and milk, and become very fat, and a very delicate bird; but they are obliged to be kept in the dark, for as foon as the leaft light is admitted they begin to fight. They are ufually taken with nets, while vaft numbers of them are fighting together. *Ray*'s Ornitholog. p. 224, 225.

RUFFE is alfo the name of a particular fpecies of pigeon, called by Moore the *columba cucullata rudis*.

It is in fhape very like that fpecies of pigeon called the *jacobine*, but is larger, and has a longer beak. The iris of the eye is fometimes red, fometimes pearl coloured. The feathers of the hood and chain are much longer than the *jacobine*, though they do not come down fo low to the fhoulders of the wings, nor are they fo compact and clofe, but are apt to blow about with every little blaft of wind, and fall more backward off the head, and lie in a rough confufed manner.

It is a common thing to match the *jacobine* pigeon with this fpecies, with intent to improve its chain by the length of the *ruff*'s feathers; but the event is, that the pigeon is always worfe inftead of better, being longer beaked, and loofer in its head and chain without any real advantage. *Moore*'s Columb. p. 48.

RUGGIOLA, a fort of Spanifh flate, ferving in many places in the room of tiles and bricks. It is a flaky ftone, of the nature of fome of our grey flates, and is cut out of a mountain near Cordova; a plate of this being well heated on both fides, will retain its warmth for twenty-four hours.

The people of Cornwal and fome parts of Yorkfhire ufe a ftone, which is of a talcky nature, to warm themfelves when in bed, applying it at the feet of the bed. This they call the warming ftone from its ufe, and it will retain a fenfible heat fix or eight hours, after once moderately warming. *Plot*'s Oxfordfhire, p. 258.

RUGOSE *leaf*, among botanifts. See LEAF.

RUININE *oil*, a name given by fome authors to the oil of the *palma chrifti*, which is very common in the Weft-Indies, and is ufed by the common people in lamps. It is a delicate fweet and tranfparent oil, and has no peculiar operation in phyfic. They often give it in glyfters from one fpoonful to three at a time, and it has only the effect of common oil: but

but the leaves of the plant are one of the grand medicines of the negroes, bruiſed and applied to the head; they are thought to be an almoſt infallible remedy for the head-ach, of whatever kind, or from whatever cauſe.

RUKKAIA, in zoology, a name given by ſome to a peculiar kind of ſquirrel, found in the iſland of Ceylon. See the article SCIURUS.

RUM (*Cycl.*)—*Rum* differs from what we ſimply call ſugar ſpirit, in that it contains more of the natural flavour or eſſential oil of the ſugar cane; a great deal of raw juice and parts of the cane itſelf being often fermented in the liquor, or ſolution of which the *rum* is prepared.

The unctuous or oily flavour of *rum* is often ſuppoſed to proceed from the large quantity of fat uſed in boiling the ſugar; which fat, indeed, if coarſe, will uſually give a ſtinking flavour to the ſpirit, in our diſtillations of the ſugar liquor, or waſh, from our refining ſugar houſes; but this is nothing of kin to the flavour of the *rum*, which is really the effect of the natural flavour of the cane. The method of making *rum* is this:

When a ſufficient ſtock of the materials is got together, they add water to them, and ferment them in the common method, though the fermentation is always carried on very ſlowly at firſt; becauſe, at the beginning of the ſeaſon for making *rum* in the iſlands, they want yeaſt, or ſome other ferment to make it work; but by degrees, after this, they procure a ſufficient quantity of the ferment, which riſes up as a head to the liquor in the operation, and thus they are able afterwards to ferment and make their *rum* with a great deal of expedition, and in large quantities.

When the waſh is fully fermented, or to a due degree of acidity, the diſtillation is carried on in the common way, and the ſpirit is made up proof: though ſometimes it is reduced to a much greater ſtrength, nearly approaching to that of alcohol or ſpirit of wine, and it is then called double diſtilled *rum*. It might be eaſy to rectify the ſpirit, and bring it to much greater purity than we uſually find it to be of; for it brings over in the diſtillation a very large quantity of the oil; and this is often ſo diſagreeable, that the *rum* muſt be ſuffered to lie by a long time to mellow before it can be uſed; whereas, if well rectified, it would grow mellow much ſooner, and would have a much leſs potent flavour.

The beſt ſtate to keep *rum* in both for exportation, and other uſes, is doubtleſs that of alcohol, or rectified ſpirit. In this manner it would be tranſported in one half the bulk it uſually is, and might be let down to the common proof ſtrength with water when neceſſary: for the common uſe of making punch, it would likewiſe ſerve much better in the ſtate of alcohol; as the taſte would be cleaner, and the ſtrength might always be regulated to a much greater exactneſs than in the ordinary way.

The only uſe to which it would not ſo well ſerve in this ſtate, would be the common practice of adulteration among our diſtillers; for when they want to mix a large portion of cheaper ſpirit with the *rum*, their buſineſs is to have it of the proof ſtrength, and as full of the flavouring oil as they can, that it may drown the flavour of the ſpirits they mix with it and extend its own. If the buſineſs of rectifying *rum* was more nicely managed, it ſeems a very practicable ſcheme to throw out ſo much of the oil, as to have it in the fine light ſtate of a clear ſpirit, but lightly impregnated with it; in this caſe it would very nearly reſemble arrac, as is proved by the mixing a very ſmall quantity of it with a taſteleſs ſpirit, in which caſe the whole bears a very near reſemblance to arrac in flavour.

Rum is uſually very much adulterated in England, ſome are ſo barefaced as to do it with malt ſpirit; but when it is done with molaſſes ſpirit, the taſtes of both are ſo nearly allied that it is not eaſily diſcovered. The beſt method of judging of it is, by ſetting fire to a little of it; and when it has burnt away all the inflammable part, examining the phlegm both by the taſte and ſmell. *Shaw*'s Eſſay on Diſtillery.

RUMI, in the materia medica, a name given by Aviſenna and Serapio to maſtic of the finer kind. They diſtinguiſhed this drug into two ſorts; the one called by this name *rumi*, which was white and pure; the other called *cupti*, which was foul and blackiſh; the former came from the iſland of Chios, the latter from ſome part of Ægypt.

RUMOUR, in law. Spreading falſe *rumours* is criminal and puniſhable at common law. 1 *Hawk.* P. C. 234.

RUMPHIA, in the Linnæan ſyſtem of botany, the name of a plant which makes a diſtinct genus. The characters of which are, that the cup is a one leaved perianthium, divided by three notches at the extremity, and is placed erect, and is plain. The flower is compoſed of three petals, which are all oblong, obtuſe, and equal in ſize. The ſtamina are three pointed filaments of the length of the flower. The antheræ are very ſmall. The piſtil has a roundiſh germen. The ſtyle is pointed, and of the ſame length with the ſtamina, and the ſtigma is three cornered. The fruit is a ſkinny drupe of a turbinated form, and furrowed in three places. The ſeed is a whole nut of an oval figure, containing three cells, the nuts in each of theſe are three cornered in ſhape. *Linnæi* Gen. Pl. p. 9.

RUN (*Cycl.*)—RUN, in the manege. To *run* a horſe is to put him to his utmoſt ſpeed. Some uſe the word *running* for any kind of gallop.

RUNCARIA, in our old writers, ſignifies land full of brambles and briars. 1 Inſt. 5. The word comes from the Latin *runca*, a weed. *Blount.*

RUNCATION, a term uſed in the antient huſbandry, to expreſs the clearing away the weeds from among the corn and other ſown plants.

They uſed when the corn or other plants were an inch or two high, to draw a ſort of rake or harrow over the ground indiſcriminately over the corn and weeds, and when this was done a perſon followed over all the field, and picked up all the weeds with the hand; the treading down the young corn, however, by this perſon's feet, and the injury done to it by the rake, were ſo great, that the crop always ſuffered greatly by it; and many of the Romans choſe to omit the uſe of the rake or harrow, as a thing that did as much injury to the corn as to the weeds, and contented themſelves with the ſending a perſon to pick up the weeds without it.

This was a ſort of firſt hint to the horſehoing huſbandry of the moderns, though ſo injudiciouſly managed, that it was of very little, if any, uſe in this its infancy. But had theſe farmers been inſtructed to ſow their corn in rows, and then to uſe the rake or harrow as we do the hoe, only between thoſe rows, they would then have had all the advantage of deſtroying weeds by it, and of ſtirring the earth, and no injury would be done to the crop. *Tull*'s Huſbandry. See the article HUSBANDRY.

RUNGS, in a ſhip, the ſame with the floor or ground timbers, being the timbers which conſtitute her floor, and are bolted to the keel, whoſe ends are *rung-heads*.

RUNG-*heads*, in a ſhip, are made a little bending to direct the ſwip or mold of the *futtocks* and naval timbers: for here the lines, which make the compaſs and bearing of a ſhip, do begin.

RUNIC (*Cycl.*)—In ſeveral parts of Sweden, ſtones may be met with which were formerly ſet up as obeliſks in memory of the dead; and theſe monuments are marked with the antient northern letters called *runor*, or the *runic* characters. In ſome places, the characters vary from the *runic*, particularly in free ſtones found in Helſignland, of which Mr. Celſius has given us a deſcription, with an explanation. See Phil. Tranſ. N° 445. Sect. 3.

From theſe Helſingland inſcriptions an alphabet of ſixteen letters may be derived, which is very ſingular. In other alphabets different ſounds are generally denoted by different figures; but here the ſame character, according to the diverſity of its place and altitude between two parallels, denotes different ſounds.

But theſe characters, however different they may appear at the firſt ſight from the *runic*, may eaſily be derived from them; or *vice verſa*, the *runic* may be derived from the *helſingic*, if theſe be ſuppoſed the moſt antient. The ſubtraction of a perpendicular line in the firſt caſe, or its addition in the latter, brings the two characters to a near reſemblance.

The inſcription, which Mr. Celſius conſiders, was publiſhed in Monſ. de la Motraye's travels, but erroneouſly. See Phil. Tranſ. loc. cit.

RUNNING, in antiquity, made one of the exerciſes performed in the pentathlon or quinquertium. See the article PENTATHLON, *Cycl.*

This exerciſe was in ſo great eſteem among the antient Greeks; that ſuch as prepared themſelves for it, thought it worth their while to burn, or parch their ſpleen, becauſe it was believed to be an hindrance to them.

Indeed, all thoſe exerciſes, that conduced to fit men for war, were more eſpecially valued; and that ſwiftneſs was eſteemed ſuch in an eminent degree, appears from Homer's giving his hero the epithet of πόδας ὠκὺς Ἀχιλλεύς. *Pott.* Arch. Græc. l. 2. c. 21.

RUNNING *of the eyes*, in infants. See INFANT.

RUNNING-*fights*, at ſea. See FIGHTS.

RUNNING-*ropes*, in a ſhip, are thoſe which run on blocks and ſhivers.

RUNOR. See the article RUNIC.

RUNT, the name uſed with the diſtinction of places for ſeveral ſpecies of pigeons. Theſe are the Leghorn, the Spaniſh, and the Frieſland *runt*, &c. The *columba domeſtica Piſarum*, *Hiſpaniæ* & *Friſiæ* of Moore.

The Leghorn *runt* is a ſtately large pigeon, ſeven inches or better in the legs, cloſe feathered and faſt fleſhed, extremely broad breaſted, and very ſhort in the back. He carries his tail, when he walks, ſomewhat turned up like a duck's; his neck is longer than any other pigeons, and he carries it bending like a gooſe or ſwan. He is gooſe headed, and his eye lies hollow in his head, with a thin ſkin round it, like that of the Dutch tumbler. His beak is very ſhort for ſo large a bird, and has a ſmall wattle on it, and the upper chap falls a little over. It is a very valuable pigeon, but is tender, and requires care.

The

The Spanish *runt* is the longest bodied of all the pigeons; it is short legged, and loose feathered, and does not walk so upright as the Leghorn *runt*. These are of a great variety of colours, but are apt to have accidents in sitting, from their sitting too heavy, and often breaking their eggs.

The Friesland *runt* is a large pigeon, and has all its feathers reverted, or looking as if placed the wrong way.

The Roman *runt* is a pigeon of the same general make with the common kind, but so large and heavy that it can hardly fly.

The Smyrna *runt* is middle sized, and is feather footed, and that to such a degree sometimes, as to look as if there were wings upon the feet; the feathers of these are sometimes four or five inches long, and often pull the eggs and young out of the nests. The common *runt* is the common blue pigeon kept for the table, and known to every body. *Moore's* Columb. p. 42.

RUNT is also a name given to Canary birds when three years old. See CANARY and PASSERES *Canarienses*.

RUPELLENSIS *sal*, in chemistry, a name given to a peculiar kind of salt, invented by Mr. Seignette at Paris, and extolled as a very valuable medicine.

The preparation of it was kept a great secret, till discovered by some members of the Paris academy. It was found to be a species of *sal polycrestum*, and was properly a soluble tartar composed of cream of tartar, and the fixed salt of common pot-ashes well depurated. This salt is of a very singular nature; for though it be a true alcaline salt, it yet is capable of crystalization, and it does not easily dissolve in the open air as other fixed salts do; but, on the contrary, it calcines therein like vitriol and the Glauber's salts. Phil. Transf. N° 436.

Another peculiar property of it is, that if it be satiated with vitriolic acids, and the liquor be evaporated, there is obtained a salt which has the figure of Glauber's salt, and all the properties requisite to make Mr. Seignette's salt. In order to which, take salt of kali or pot-ashes of Alicant well purified one pound; dissolve it in water, and add to it cream of tartar half a pound: this is about the quantity usually necessary; but the true proportion, in this case, can no more be determined than in the making the common soluble tartar, otherwise than by trial every time; either from the salt of kali's having retained more or less humidity, or from the tartar's having more or less foulness. Boil the whole together in order to dissolve the tartar; and if the quantity of tartar have been too great after the fermentation is over, filtre the liquor, and as it cools the superfluous tartar will fall to the bottom: after the separation of the tartar, evaporate the lixivium over a gentle fire to a proper standard, and then set it in a cool place, and there will shoot fine crystals. If the liquor be a little too far evaporated, there will be no crystals formed, but the whole liquor will congeal into a hard substance transparent like ice; but upon dissolving this in more water, it will shoot as fair as it would have done if properly evaporated at first.

The virtues of this salt consist in its being an excellent purge, its dose is from one to two ounces; and it is to be dissolved in a large quantity of water.

RUPERT's drops, a sort of glass drops with long and slender tails, which burst to pieces, on the breaking off those tails in any parts, said to have been invented by Prince Rupert, and therefore called after his name.

This surprising phænomenon is supposed to arise from hence; that while the glass is in fusion, or in a melted state, the particles of it are in a state of repulsion; but being dropped into cold water, it so condenses the particles in the external parts of their superficies, that they are thereby reduced within the power of each other's attraction, and by that means they form a sort of hard case, which keeps confined the before-mentioned particles in their repulsive state; but when this outer case is broke by the breaking off the tail of the drop, the said confined particles have then liberty to exert their force, which they do by bursting the body of the drop, and reducing it to a very peculiar form of powder.

This theory seems to be corroborated by making the drops red hot, and letting them cool again by gentle degrees in the open air, for then there is no such effect. Yet it must be allowed, that there is another experiment which seems to impugn this hypothesis; and that is by grinding away any part of the drop upon a grindstone, when the remaining part continues entire; though there appears no reason why it should not break, and burst into dust, if the internal parts be the cause of it; since by this means they must needs be set at liberty, in the most ample manner possible, unless it be that in grinding, the vacuities between the internal particles are filled up with the matter worn off from the stone; and by this means fixing the parts of the glass next the stone, they destroy their repulsive force; constituting as it were another sort of hard external case, which confines the internal particles no less than the other did.

The history of these drops is this; they were first brought into England by prince Rupert out of Germany, and shewn to king Charles II. who communicated them to the Royal Society at Gresham College; and a committe appointed on this occasion by the Society, gave the following account of them. They must be made of green glass well refined, for till the metal, as the glass men call it, is perfectly refined they never succeed if made of it; but always crack and break soon after they are dropped into the water. The best way of making them is to take up some of the metal out of the pot upon the end of an iron rod, and immediately let it drop into cold water, and there lie till it is cold. If the metal be too hot when it is dropped into the water, the business does not succeed, but the drop frosts and cracks all over, and falls to pieces in the water, and every one that does not crack in the water, but lies in it whole till it is quite cool, is sure to be good: there is great nicety in the hitting a due degree of heat in the metal, and the workmen who best know their business cannot promise beforehand which shall succeed, but often two fail for one that hits right. Some of them frost over the surface without falling to pieces, and others break into pieces before the red heat is quite over, and that with a small noise; others break soon after the red heat is over and make a great noise, and some neither break nor crack till they seem to be quite cold; and others hold together while they are in the water, but fly to pieces with a smart noise when they are taken out of it; some do this on the instant, others an hour or two after, and others will keep several days, nay weeks, and at last fall to pieces without being touched. *Neri's* art of glass by Merrett. p. 356.

If one of them be taken out of the water while it is hot, the small part of the neck and so much of the thread or string it hangs by, as has been in the water, will upon breaking fall into small parts, but not the body, though it have as large cavities in it, as those which burst in pieces.

If one of these drops be cooled in the open air hanging on a thread, or on the ground, it becomes like common glass in hardness, solidity, and all other its qualities, and has nothing of the nature of the drops cooled in water.

When a glass drop falls into the water, it makes a hissing noise, the body of it continues red a pretty while, and there proceed from it many eruptions like sparkles that crack, and make it leap up and move, and several bubbles arise from it till it cools; but if the water be ten or twelve inches deep these bubbles diminish so in the ascending, that they vanish before they attain the superficies of the water, where nothing is to be observed but a little thin steam.

The outside of the glass drop is close and smooth like other glass, but within it is full of spungy cavities and blebs. The figure is a sort of oval or pear like shape, such as pearls are painted in, the bottom of which is rounded, and the top terminates in a long neck which is usually variously bent and crooked. Almost all those that are made in water have a little protuberance or knob, a little above the largest part of the body, and most commonly placed on the side toward which the neck ends, but sometimes it is upon that side that lies uppermost in the vessel where it is made.

If the water be hot into which the glass drop is thrown, it always cracks and breaks in the water, either before the red heat is over or very soon after. If dropped into oil they do not miscarry so often as when dropped into water: they produce also a greater number of large bubbles, and continue longer bubbling than when dropped into water: those made in oil have also fewer blebs, and smaller than those which are made in water; and frequently they are smooth all over, not having those knobs which the others have. Some part of the neck of these also, and part of the small thread that is quenched in it, cooled, breaks like common glass; but if the neck be broken off near the body, and the body held all the while close in ones hand, it will crack and break all over; but even then it flies not into so small parts, nor with so smart a force and noise as those do which are made in water, and the pieces will hold together till they are parted, and there then appear long streaks or rays upon them, pointing toward the center of the body, and thwarting the little blebs in it.

If the drops are dropped into vinegar, they frost and crack, so that they are sure to fall to pieces before they are cold, and the noise of their falling in is more loud and hissing than in water, but the bubbles are not so remarkable.

In milk they make no noise nor any bubbles that can be perceived, and never miss to frost and crack all over, and fall to pieces before they are cold. In spirit of wine they bubble more than in any other of the liquors, and while they remain entire, they tumble to and fro, and are more agitated than in other liquors, and they never fail to crack and fall to pieces; and by that time five or six of them have been dropped into this spirit it will be set on a flame, but it receives no particular taste from them.

In water wherein nitre or sal armoniac have been dissolved they succeed no better than in vinegar. In oil of turpentine, the first broke as in the spirit of wine, and the second set it on fire, so that it could not be used again. In quicksilver, being forced to sink by a stick, it grew flat and rough on the upperside; but the experiment could not be perfected, because it could not be kept under till it cooled. In an experiment made in a cylindric glass like a beaker, filled with cold

cold water, out of feven that were tried one only fucceeded, the reft all cracking and breaking to pieces; and it was obferved, in this experiment, that at the firft falling of the drop into the water, and for fome time after, while the red heat lafted, red fparks were fhot forth from the drops into the water; and that at the inftant of the eruption of thofe particles, and of the bubbles which manifeftly break out of it into the water, it not only cracks, and that fometimes with a confiderable noife, but the body moves and leaps about, and that as well in thofe which fucceed as thofe that break in the water.

A blow with a fmall hammer, or other hard body, will not break one of thefe glafs drops if ftruck upon the body; but if the tip only of the neck be broke off, it flies to fmall particles, which eafily crumble into duft; and if it be broken, when the particles have liberty to difperfe themfelves, they will fly every way in an orb, in the manner of a granado.

If they are ground down ever fo low into the body with water and emery they do not fly; but rubbed on a dry tile, they ufually fly to pieces as foon as the bottom is a little flatted, though fometimes they bear rubbing away deeper; and fome, when rubbed half down, have been laid by without burfting, and have flown to pieces a little while after without being touched.

If one of them be broken in the hand under water, it ftrikes it more fmartly than if in the open air; and if it be broken near the furface of the water, the particles it flies into do not difperfe themfelves into an orb as in the air, but all fall regularly and evenly to the bottom; and they burft in the fame manner in the exhaufted receiver of the air pump as in the open air. One of thefe drops being faftened into a cement, all but a part of the neck, and then the tip of it broken off, it made a pretty fmart noife, but not fo great as if broken in the hand; and though, on examining, it appeared to be all fhivered to pieces within, and its colour turned greyifh; yet the outfide remained fmooth, though cracked, and being taken in pieces, the parts of it rofe like thofe of the flaky bodies, talc, or the like; the flakes were many of them conical in fhape, and were alfo cracked, that they eafily fell into duft.

Another drop faftened into a ball of cement of half an inch in thicknefs upon the breaking off the tip of it, burft the ball in pieces like a granado. And when attempted to be bored by a lapidary as they bore pearls, they fly to pieces as foon as the tool enters them, in the fame manner as they do when the tip is broken off.

Thefe were the feveral experiments tried on them by the gentlemen of the royal fociety, and thefe all tend to prove the before-mentioned account of their burfting to be true; and indeed none more than the dry and wet grinding of them; the wet emery, in the latter cafe, making a coat in the place of that it wore away; and the dry powder of tile in the former, fcarce anfwering the fame purpofe, and at beft but very imperfectly, and preferving the body together only for a fmall time. *Neri's* Art of Glafs, p. 362.

RUPICAPRA, in natural hiftory, the name of a creature of the goat kind, from whofe fkin the chamois leather is made, the creature itfelf being called alfo the *chamois* by the French, and by the Germans the *gemp*. See Tab. of Quadrupeds, N° 8. It is very common in the mountains of Helvetia, and in many other places. In the figure of its body it feems to approach very much to the ftag kind; its belly, forehead, inner part of its ears and throat are white; it has a yellow ftreak on each fide near the eyes, and the reft of the body is perfectly black; its tail alfo is black, and that equally on all fides, not white on that part next the body as is the cafe in the deer. *Ray's* Syn. Quad. p. 78.

The male and female both have horns, which are a hand's breadth and an half long, rough toward the bottom, and fomewhat knotty; a new knot growing every year; they are nearly ftrait, but at the top bent into the fhape of a hook, black, and not fmooth, but longitudinally ftriated with flender ftreaks, and their inner cavity is filled up with a folid bone proceeding from the fkull.

This creature has two remarkable holes always open behind its ears: thefe fome have imagined ferved for refpiration; and Appian, who had the *poetica licentia* for whatever he chofe to fay, feems to have led them into this; but there is no fort of probability of truth in it, fince the fkull is feen immediately under thefe holes, and there is no perforation through it, nor any duct difcoverable from them. The vulgar have alfo fome remarkable opinions founded on the ftructure of the horns of this creature; the one, that in depreffing them to rub his back, he often gets them fo far within the fkin that he cannot get them out again; and the other, that he hangs by his horns to the rocks.

RUPITANI, a name given to the Donatifts. See CAMPITÆ.

RUPPIA, in botany, the name given by Linnæus to a genus of plants, called by Micheli *bucca ferrea*. The characters are thefe. The cup is compofed of a fubulated fpadix, ftrait, and of a very fimple ftructure, which becomes a little bent when the fruit is ripe, and is doubly befet with fructifications. There are no petals, nor any ftamina, but a number of kidney fhaped antheræ placed on each fide. The piftils are feveral flender capillary ftyles, each bearing an an oval germen with a fimple ftigma. The fruit is an oval, pointed, thin capfule or cortex placed on the ftyle, which becomes elongated. There are as many of thefe as there were piftils on the plant, and each contains one roundifh feed. *Linnæi* Gen. Pl. 442. *Micheli* 35.

RUSCUS, in botany, the name of a genus of plants, called in Englifh *butchers broom*. The characters of the genus are thefe. The flower confifts of only one leaf, and is of the globofe campaniform kind or hollow, with the belly or body larger than the rim. This is inclofed in a cup, divided into many fegments, and from the bafe of it rifes a piftil, which ripens into roundifh foft fruit, containing one or two feeds which are ufually very hard.

There are four fpecies of this plant. 1. The common myrtle leaved kind. 2. The broad leaved one with the flowers and fruit growing to the leaves called the Alexandrian bay. 3. The narrow leaved one with the fruit growing to the leaves, called *hippogloffum* by authors; and 4. The narrow leaved kind with the fruit growing on the tops of the branches.

Authors have not been accurate in referring the plants of this genus to their proper name *rufcus*, but the three latter have been called by different writers *hippogloffum*, *bonifacia*, *laurus alexandrina*, *chamædaphne*, *laurotaxa*, and *radix idæa*; and many of them have, in their defcriptions, miftaken the calyx of fome fpecies for the flower. *Tourn.* Inft. p. 79.

The root of *butchers broom* is one of the five aperient ones, and is celebrated by authors as a very powerful attenuant and refolvent. It is good in all chronic cafes, and is frequently prefcribed in diet drinks, intended to open obftructions of the vifcera, or to promote urine.

RUSH, in botany. See the article JUNCUS.

Petrified RUSHES. What is ufually called by this name is a kind of foffile coral. But we have in England alfo another not uncommon fubftance, frequently called by the fame name; this is an incruftation of fparry matter, in form of a ftony cruft on the outfides of real *rufhes*; though, in this cafe, it is no real petrifaction, but only a covering of this ftone-like matter. Incruftations and petrifactions are ufually confounded together, and the generality of people do not attend to the diftinction, which is, that in a real petrifaction, the ftony matter penetrates the very fubftance of the body, as is the cafe in the petrified wood of Ireland and other places; whereas in thefe incruftations the fubftance itfelf remains unaltered within, and its outer part alone is covered with the ftony fubftance: this is the cafe with what is called petrified mofs at Scarborough and in other parts of England, and this is the cafe in regard to what we call fometimes petrified *rufhes*. Thefe being water plants, and growing by the fides of fprings, loaded with fpar, often fall in, and become covered over with it. We have near Kettering in Northamptonfhire a fpring which does this very quickly: a gentleman who tried the experiment, by putting in fome *rufhes*, at about thirty yards from the fource, found them in one day covered with a thin fkin of fpar; but after lying fome months there, it formed itfelf into a cruft of half an inch thick round them; and was fo hard, that it would not break by being thrown violently on the ground; but all this while the *rufhes* were not petrified, but only incrufted. *Woodw.* Cat. Foff. Vol. 2. p. 78.

RUSH *grafs*. See the article JUNCAGO.

RUSMA, in natural hiftory, the name given by the eaftern nations to the fubftance, called by the antient Greeks *fory*. It is properly an ore of vitriol, and is ufed as a depilatory, being mixed with lime. *Hill's* Hift. of Foff. p. 6. See the article SORY.

Mr. Boyle tells us, he made a fine powder of equal parts of *rufma* and quick-lime, and letting them foak a little time in water they became a foft pafte, which he fpread on the part he would free from hair; and after letting this pafte lie on about three minutes he wiped it off with a wet cloth, and found the hair taken away by the roots, without any inconvenience to the part. *Boyle's* Works Abr. Vol. 1. p. 137.

Orpiment and quick-lime is ufed in Europe for a depilatory. See the article HAIR, *Cycl.*

RUSSGANGENUM, in natural hiftory, a name given by the people of the Eaft-Indies to a yellow and brafs like foffile fubftance, found in many places there; it refembles the marcafites, only that on trial it is found to contain very little fulphur: it is probably an ore of zink.

RUST *of corn*, or BLIGHT, in hufbandry, the name given by our farmers to a difeafe in corn and other vegetables, in which their ftalks and leaves feem burnt up, and appear of a fort of *ruft* colour.

Wheat is blighted at two feafons, firft in the bloffom, and then its generation is prevented, many of the hufks being empty in the ear, and the rudiments of the grains not impregnated: fecondly, wheat is blighted when the grains are brought to maturity; and in this cafe they become light, and are of little value for making of bread, having fcarce any flour in them.

The firft of thefe cannot happen in England from frofts, becaufe our wheat is not in flower till the month of June; but

but it is long and continual rains that chill the bloffoms, and in this manner prevent their fertility: this, however, does not often happen to us; thefe rains are not common at this feafon of the year; and if they were, this country lying much of it open, the winds diflodge thefe drops of water from the ears, and prevent the mifchief they would do there.

Lammas wheat does not retain thefe drops fo long as the bearded or cone wheat; and, in confequence of this, in the terrible blight in England in the year 1725, the bearded wheat received infinitely greater mifchief than the lammas wheat.

The fecond kind of *blight* from light ears, is, that which is more frequent, and more general with us; this brings the greateft fcarcity of wheat, and the caufe of this is plainly want of nourifhment of the grain, by whatever means that want is occafioned. Several accidents kill the plants, or injure their health, and in that cafe the grains are not filled: lightning does great mifchief to the farmer in this kind, as is plain by the feveral black fpots and patches in fields of corn, in years, when there has been more lightning than ufual. This is a difafter that muft be quietly fuffered, fince it can be neither prevented nor remedied; but the other caufes of *blights*, which are moft general, and do the moft damage, may be prevented in fome meafure at leaft.

One great and common caufe of the *blight* is, the lodging or falling of corn; in this cafe the ftalks are broken near the ear, and the veffels are hurt which fhould carry up the nourifhment to the ear. In this cafe, there can juft juices enough pafs for the keeping the plant alive, and bringing it to its full height, but it is languid all the time, and the grains can never be filled with flour. The earlier in the feafon this lodging of the ftalks happens, the thinner and poorer the ears will be: hence it happens, that when dung and tillage have brought a wheat land into fo good a ftate, that in April and May it feems to promife the farmer five or fix quarters of wheat, it fhall be all deftroyed by falling in June, and fcarce yield him five bufhels, and this fo thin and lank, that the expences of reaping and thrafhing are more than its value. The wind is generally accufed of the throwing down thefe ftalks, but this does not feem to be truly the cafe; the wind may prefs upon the plants; but the caufe of their giving way to it is a weaknefs in their ftalks, and this feems owing either to the want of nourifhment, or the want of air, or of the fun's rays, and perhaps to the want of all three together.

A rich acre will maintain a crop of five quarters ftanding, while a poor acre will not be able to fupport fuch a crop, as would have yielded only about three quarters had it ftood. This is a proof of want of due nourifhment being one great caufe of the falling. Air is neceffary to the nourifhment of all plants, wheat in patticular requires a very free air. It fucceeds beft in open hilly places where the wind comes freely to it, and fhakes off the drops of water from the leaves, as well as their own recrements; and it is plain, that a great quantity of the fun's rays is neceffary to keep wheat ftrong; becaufe in the hotter countries it is not fubject to fall as it is with us, and in other northern countries.

There is another caufe of the *blight*, which is the wheat's coming too late into bloffom. It fhould bloffom in the beginning of June, becaufe there is not otherwife time during the hot weather for it to pafs through the different ftages to the perfection of the grain.

The caufes of the *blight* being thus known, the cure or prevention may be attempted by the farmer, on much more rational grounds than it was among the antients. It is advantageous to haften as much as poffible the time of bloffoming of the corn, and to protract as long as we can the ripening of the grain, that it may have fufficient time to fill and fwell. The earlieft fown wheat is generally obferved to efcape the *blight* beft, and this is owing to its coming fooneft into bloffom. The antients ufed to let their fheep feed upon the corn while young in the blade, by way of preventing it from lodging or falling afterwards: fome of our own farmers ufe this method alfo; and, it is true, that the corn is prevented from falling by this; but the remedy is as bad as the difeafe, for the ftalks are not made very ftrong by this practice, but the ears lighter. They therefore do not weigh down and lodge the ftalks indeed, but they are in fome fort blighted by this means, and the difeafe is caufed by the means ufed to prevent it. This feeding the wheat with fheep retards the time of its bloffoming, and the only advantage of early fowing is thus taken away by it: what grows after the eating of the fheep is a fort of latter crop, and is always weaker and later than the firft. The longer the corn remains on the ground the more nourifhment it requires from it; and in this unnatural remaining on the land, there is no proper fupply provided.

The general remedy for all the cafes of the *blight* is the modern method of horfehoing hufbandry. In this the hoe ftirs up the ground as often as the farmer pleafes, and every fuch ftirring gives new life and nourifhment to the plant: this way a fupply of food for the ear may be given, whenever it is neceffary, and the wide intervals left for the hoe in the drilling the wheat; for this fort of hufbandry gives a free paffage for the fun and air to all the plants.

The moft general *blight* of all that happen in thefe cold countries is caufed by infects, which fome think are brought in the air by an eaft wind, accompanied by moifture, a little before the grain is filling with that milky juice which hardens into flour. Thefe infects depofite their eggs within the outer fkin or rind of the ftalks; and when the young ones are hatched they feed on the parenchyma, and eat off many of the veffels which fhould convey this juice; then the ear is deprived of it, and muft in confequence be thin and poor, in proportion to the number of the veffels eaten, and as the infects happen to come earlier or later; for fometimes they come fo late, that the grains are fufficiently filled with this milky juice before they have any power to hurt the veffels.

In this cafe, though the ftraw, when examined by the microfcope, appears to have its veffels eaten and torn, and to be full of black fpecks, which are caufed by the fame infects, yet the grain is plump and full. This is one of the many cafes in which the early fown wheat efcapes the *blight*. It has been feen, that of the crop of wheat, in the fame field, fome of which has been fown earlier and fome later, though there has been no other difference in the whole, yet the early fown wheat has been full eared, and the late fown has been light eared; and both have had their ftalks equally eaten and fpotted by the infects.

A proof that thefe mifchievous infects are brought by the eaft wind, is, that the corn on the eaft fide of hedges is often found *blighted*, and deftroyed by them, while that on the weft fide of the fame hedge is unhurt. Some fuppofe they are bred in the earth, and crawl up the ftalks, becaufe fome whole fields are fubject to them, and others efcape them wholly; but this is more probably owing to the difference of the fituation of thefe fields, as they are more or lefs expofed to the eaft. Some wheat is more liable to be hurt by this infect-*blight* than another, and the beft remedy in this evil is to plant fields which are moft expofed to thefe *blights*, with fuch wheat as is leaft fubject to be injured by them. The white cone, or bearded wheat, which has its ftalk or ftraw like a rufh, not hollow, but full of pith, except near the lower part, where it is very thick and ftrong, is very proper on this occafion; it is probable, that this plant has fap veffels, that lie deeper, and fo are not to be deftroyed like thofe of common wheat; the ftalks of this are often found fpotted with black, which fhews that the infects have been there, and yet the ears are found full, and the grains plump in them.

There is another kind of *blight*, called by the farmers *moor loor*, this is occafioned by the earth's falling away from the roots of the wheat, and is cured by throwing up fmall furrows againft the rows in the drilling method. The horfehoing hufbandry is beft of all others calculated to prevent *blights*, and to cure them when they happen; but as there are fome years when all wheat is *blighted*, even at thefe times, the horfehoing hufbandry has an advantage; for when the ftalks fall they never lie abfolutely on the ground in this cafe, but the air has room to play between them; but the common fown wheat has not this advantage. The ears in the *blighted* wheat of the drilled kind are not fo light nor poor as in others, but make the farmer fome amends in the corn, though greatly lefs than in the common produce. *Tull*'s Horfehoing Hufbandry.

Corn is always more fubject to *blights* after a wet fummer than at any other feafon; the reafon feems, that the roots being continually drenched with water, the plant runs up to ftalk, and has very little ear, and the corn in the ear is never large or full.

It is obferved, that when the mildews rife or *blights* fall, they generally infeft only one kind of grain, fometimes wheat, fometimes oats, and fometimes barley only; and the fame fort of obfervation holds good in regard to fruit, fometimes only apples are *blighted*, fometimes only pears, fometimes cherries, and fo on. *Mortimer*'s Hufbandry. T. 1. p. 305. See the article BLIGHT.

RUSTICULA, in zoology, a name by which Aldrovand and fome other authors have called the *godwit*, more commonly known by the name *ægocephalus*. *Aldrovand.* de Avib. See the article ÆGOCEPHALUS.

RUSTICULA *brafilienfis*, in zoology, the name given by Mr. Ray, and fome others, to the *guarauna*, a water bird of the Brafils, of the fize of our fnipe. See GUARAUNA.

RUT (*Cycl.*)—RUT *of the fea*, is where it dafhes againft any thing.

RUTA, *rue*, in botany, the name of a genus of plants, the characters of which are thefe. The flower is of the rofaceous kind, ufually confifting of four hollowed petals, difpofed in a circular form. From the cup of the flower there arifes a piftil, which afterwards becomes a roundifh fruit, approaching to a fquare form, and compofed of four capfules affixed to an axis, and ufually containing angular or kidney fhaped feeds.

The fpecies of *rue* enumerated by Mr. Tournefort are thefe. 1. The common broad leaved garden *rue*. 2. The more fhrubby broad leaved garden *rue*. 3. The narrower or fmaller leaved garden *rue*. 4. The larger wild *rue*. 5. The fmaller

fmaller wild *rue*. 6. The broad leaved *rue* with hairy flowers. 7. The narrower leaved *rue* with hairy flowers. 8. The white-flowered coriander-leaved prickly mountain *rue*. 9. The Spanifh flax-leaved wild *rue*.

The *rues* would feem to belong properly to the plants, with cruciform not rofaceous flowers; but that the number of the petals in each flower is in the cruciform flowers, always determinately four; but in this genus, as in the other rofaceous ones, it is fometimes four, fometimes five. *Tourn.* Inft. p. 257.

Rue has always been held in great efteem as a cephalic and alexipharmic. It is good in all nervous difeafes, fevers, fmall-pox, meafles; and greatly fo in hyfteric cafes. It is given by many to ftrengthen the ftomach, and to prevent the return of habitual colics. It has alfo been given in pleurifies and peripneumonies, and againft the bites of venomous animals. There ufed to be a conferve and a fimple water of *rue*, but both are now rejected.

RUTA *muraria*, *wall-rue*, in botany, the name of a genus of plants, the characters of which are thefe. The leaves are of a fhape nearly refembling thofe of garden *rue*. The flower is not difcovered, but the fruit are a number of roundifh membranaceous capfules furrounded by an elaftic ring, on the contraction of which they burft and throw out a great number of minute feeds.

The fpecies of *wall-rue* enumerated by Mr. Tournefort are thefe. 1. The common *wall-rue*. 2. The broad leaved alpine *wall-rue*. 3. The taller German *wall-rue*; and 4. The tall climbing *wall-rue* with various leaves. See Tab. 1. of Botany, Clafs 16. *Tourn.* Inft. p. 541.

RUTICILLA, in zoology, the name of a fmall bird, called by the Greeks *phœnicurus*, and in Englifh the *red-ftart*. Its breaft and rump are of a reddifh brown, the lower part of its belly is white; its head, neck and back of a gloffy lead colour; the head is marked before with a very fine white fpot, which is feparated from the eyes and beak by a black line. Its throat is black, with an admixture of grey at the tops of the feathers. Its long wing feathers are all brown; its tail is compofed of twelve feathers, the five outer ones of each fide red, the two middle ones blackifh. Its legs and beak are black, and its mouth yellow within. It feeds on flies, beetles, fpiders, *&c.* *Ray's* Ornithol. p. 159.

RUTILUS, in zoology, a very well known river fifh, called in Englifh the *roach*, remarkable for its livelinefs and vivacity.

In fome parts of the world this fifh will only live in ftanding waters; with us it equally thrives in ponds and rivers, and is remarkable for its numerous progeny; a pond being much fooner ftocked with this than with any other fifh. *Ray's* Ichthyog. p. 262.

RUTILUS *latior*, in zoology, a name given by many authors to the fifh called in Englifh *rudd* or *finfcale*, and more ufually in Latin *rubellio fluviatilis*. Id. Ibid. p. 252.

RUTTEE, a weight ufed in the Eaft Indies, one hundred of which make eighty-eight caracts. See CARACT.

RUTULUS, in Roman antiquity, the barrier of the cavea, or place where the wild beafts ufed in amphitheatrical fports were fhut up. It was made of iron bars, which turned upon hinges, and all at once flew open with great fwiftnefs. See *Pitifc.* Lex. Ant. in voc. *rutulus* and *cavea*.

RUTY-PUNDOC, in natural hiftory, a name given by the people of the Eaft Indies to a peculiar fpecies of yellow orpiment, which they find on the tops of the mountains there; and after feveral calcinations give internally in coughs and colds. The antient Greeks ufed this orpiment in the fame manner; we have of late run into an opinion of its being a fatal poifon. But Dr. Boerhaave, in his chemiftry, affirms, on his own trials, that it is innocent and harmlefs. Thefe people, who have not the ufe of chemiftry, give us a hint of the virtues of great numbers of our own foffils, which are common alfo to their country. The felenitæ, fibrofe talcs, fpars, and many other foffils, which we wholly neglect, are in common ufe with them, and great cures are often performed by them. *Woodw.* Cat. Foff. Vol. 2. p. 13.

RYE, *fecale*, in botany. See the article SECALE.

This fort of grain fucceeds very well on any fort of dry land, even on the moft barren gravel or fand. The farmers fow it about the beginning of September, after a fummer's fallow, in the drieft time they can. Two bufhels of feed is the quantity generally allowed to an acre of land; but if it be ground newly broken up, or if it be fubject to worms, they then allow a peck more to the acre. A little fprinkling of dung, or mud, upon *rye* land, will greatly advance the crop, though it is laid but half the thicknefs that it is for other corn; its produce is commonly about twenty bufhels upon an acre.

The farmer knows it is ripe when the ftraw is yellow, the ear bends, and the grain feels hard. It is not apt to fhed the feeds; and therefore, if there are many weeds among the crop, it may be left lying upon the ground, or gravel, as they call it, eight or nine days after it is cut, before it is bound up, if the weeds are not dry fooner: for otherwife, they will grow moift in the barn, and caufe the whole to give, and not to thrafh well, and fometimes they will make it mufty.

As it is a grain that will grow in the ear fooner than any other if it be wet, care muft be taken if rain falls after it is cut, to turn it as it lies on the ground every other day; and at the fame time to keep the ears as far from the earth, and as much above the ftubble as may be; this will prevent the mifchief. If it be pretty clear of weeds it may be houfed as foon as it is cut. If either this grain or wheat lodge upon the ground, it is beft to cut them, even though they are not ripe; for the ftalk being broken will yield no more nourifhment to the ear.

There is another very effential ufe to the farmer made of *rye*. April is the feafon of the year when food is of all others the fcarceft for cattle, efpecially for fheep and lambs: on this occafion fome fplit the ridges of the wheat ftubble and fow them with *rye*; they harrow this in, allowing about a bufhel to an acre: they feed the fheep with this in April, and in May they plow it up for fallow. *Mortimer's* Hufbandry, p. 136.

In many parts of France there have been certain years, in which this grain, from no apparent caufe, has proved noxious, and fometimes even poifonous. Mr. Perrault travelling through Sologne, was informed that the *rye* of that province was fometimes fo corrupted, that thofe who eat of the bread that had much of the corrupted grain in it, were feized with gangrenes in different parts of the body, which was not preceded by any fever, inflammation, or any confiderable pain; and that the gangrened parts ufually fell off after a time of themfelves, without the affiftance of chirurgical inftruments.

The grains of *rye* thus degenerated are black on the outfide, and tolerably white within; and when they are dry, they are harder and clofer than the natural good grain: they have no ill tafte, but fometimes they have a vifcous metallic like honey hanging to one end of them. They grow longer than the other grains in the fame ear, and are found from one or two, to feven or eight in the fame ear. Some have fuppofed that thefe were not the proper feeds of the plant, but fome other extraneous bodies that got in among them; but it is evident, from a clofe infpection, that they are really the genuine feeds only altered by fome accident; the coats, and the furrow, and even the germen for the young plant, being entirely the fame as in the natural feeds.

The places where the *rye* is found to degenerate in this manner, are all a dry and fandy foil. In thefe places there is fcarce any foil in which more or lefs of thefe large feeds are not found among the others, but where there are but few of them the ill effects are not perceived. The feafons when the degeneracy is greateft, and the effects the worft of all, is, when there have been exceffive rains in the fpring, and there come on exceffive heats in the fucceeding fummer.

The bread which is made of the *rye* that holds ever fo much of this bad corn, is not diftinguifhable from other *rye* bread by the tafte, and feldom produces its ill effect, till fome confiderable time after it is taken. Befide the gangrenes already mentioned, it not unfrequently brings on other bad confequences, fuch as drying up the milk of women who give fuck, and occafioning fometimes malignant fevers, accompanied with drowfinefs, ravings, and other dangerous fymptoms. The part ufually feized by the gangrene is the legs, and this often in a very frightful manner. The arms are the part moft fubject next, but all the other parts of the body are fubject to it.

The firft fymptom of this approaching gangrene is a ftupefaction and deadnefs in the part; after this there comes on fome pain, though not violent, and the fkin becomes livid; fometimes the fkin fhews no mark of it, but the pain and fwelling increafe; and it is neceffary to make an incifion into the flefh to find the gangrened part. In the more defperate cafes, the only remedy is the taking off the part; and if this is neglected, the flefh is all wafted, and the fkin becomes black, and clings round the bones, and the gangrene appears again in the fhoulders.

The poorer people are only fubject to this difeafe; and, as they principally eat the *rye* bread; and as thofe years when there is moft of this bad grain among the ears of *rye* produce moft of thefe diforders, it has been judged certain that the *rye* is the occafion of it. It may deferve enquiry, however, whether that grain may not be innocent of the mifchief, and its degeneracy and the diftemperature attributed to it may not both be the effect of the fame bad conftitution of the air. If it proves, on enquiry, that only thofe who eat of the *rye* are fubject to the difeafe, it will feem a proof of its being really owing to it; and in this cafe the mifchief may be prevented by the fifting the grain before it is ground, the degenerated grains being fo long that they will all remain in the fieve that lets the others through. The experiment has been made on the fpot, by giving the flower of the corrupted grains alone to animals, and it is faid they have been killed by it. Phil. Tranf. N° 130.

RYSAGON, in the materia medica, a name by which fome authors have called the *caffumunar root*.

S.

S, in the Italian music, stands for *solo*; it is used in pieces of music of several parts, to intimate, that in such places a voice, or instrument, is to perform alone. See the article SOLO.

SABAZIA, Σαβαζια, among the Greeks, nocturnal mysteries in honour of Jupiter *Sabazius*, into which all that were initiated had a golden serpent put in at their breasts, and taken out at the lower part of their garments, in memory of Jupiter's ravishing Proserpina in form of a serpent. *Potter*, Archæol. Græc. l. 2. c. 20. T. 1. p. 429.

SABINA, *savin*, in medicine. See SAVIN.

SABINITES *lapis*, in natural history, a name given to a stone in which are preserved the leaves of the common savin. See the article *fossile* PLANTS.

SABLE (*Cycl.*)—SABLE, in zoology, the name of the animal whose fur is so much valued, and sold under the same name. It is a creature of the weasel kind, and called by authors *mustella zibellina*. See the article ZIBELLINA.

SABLE *mouse*, in natural history, the name of an animal found in Lapland, and in other cold countries; many extraordinary things are related of the manner of living of these creatures.

They are of the bigness of a squirrel, and their skin is streaked with brown and black; there are also some spots beside the streaks; the black is a very fine deep colour, the brown is pale; they have two very sharp teeth above, and two below of the same kind; their feet are like a squirrel's, and they have no tail; they are usually very fat and fleshy, and are so quarrelsome and fierce an animal, that if a stick be held out to them they will bite at it, and will hold it so fast, that they may be tossed and swung about in the air by it without letting it go. In their march they usually keep a direct line from north east to south west, and always travel in thousands in the same troop. The whole number forms a square body, and they march only from the time of the twilight to the morning, lying still all the day.

They march in lines, which are some ells distant, but always exactly parallel to each other, so that the places they have gone over look like the furrows of a ploughed field. If they meet with any thing in their way that might deter another animal, it never stops them; but, though it be fire, a deep well, a pond, a torrent, or a bog, they without hesitation venture through, and by that many thousands of them are destroyed, and are found dead in the morning, in the waters, or otherwise.

If they be met swimming over lakes, and attacked by men in boats with the oars, boat hooks, or other instruments; they neither retreat nor offer to run up the oars, but hold on their course; and if they be put out of it they presently return into it again. When they are met in the woods or fields, they set themselves up on their hinder feet, and make a sort of squeaking noise, somewhat like the barking of a dog; they will leap up at a man, and rise as high as his head, and in this manner they will defend their line a long time; but if they find themselves overpowered, they will disperse and run into holes, or any other places of secrecy, making a noise, which sounds something like the word *biob, biob*.

They never come into a house, nor meddle with any thing that we eat; if they chance to come to a house in their way, there they stop till they die; but if they come to a stack of hay, or corn, they eat their way through.

When they march over a meadow they do it great damage, by eating the roots of the grass; but if they encamp there, they wholly destroy the produce; the land looks like a place where there had been a fire, and the whole surface looks as if strewed with ashes.

They are said to be very fruitful, bringing forth eight or nine at a time; but it is certain, at least, that they bring forth more than one, for in their marches it is not unusual to see a female with a young one in her mouth and another on her back. They seem no great delicacy to creatures of prey. If dogs or cats kill them they eat only the head, and when a bird of prey seizes them it only feeds on the entrails; it is said only on the heart: the poor Laplanders, however, in want of other food eat the whole body, and say it is as well tasted as a squirrel. In the severity of winter these creatures lie under the snow, and have their breathing holes as the hares, and other inhabitants of these places use to have. The Laplanders are always glad to see these creatures on their march, for it always foretels plenty of more valuable creatures among them: the same cold that sends these out, sending also a number of fowl, squirrels, foxes, and other animals the same way. Wormius has written a complete treatise on this animal, calling it *mus norwegius*, this is reprinted at large in his Museum. Phil. Transf. N° 251. p. 112.

SABURRÆ, in natural history, the name of a genus of fossils found in form of powder, and usually confounded among the sands, and called by the same name. These are not composed like the genuine sands of pure natural concretions, but are irregular particles, seeming to have been the fragments of other large bodies. They are not to be dissolved or disunited by water, but retain their figure in it, and do not cohere by means of it into a mass. They are often very opake, and in many of the species will ferment with acids, and are often fouled with heterogene particles, taking in the coarser, stony, mineral, and metalline particles, and are according to their colour divided into several kinds.

White SABURRÆ. Of these consisting of pure spar we have three kinds. 1. A fine snow white one; and 2. A dull coarse white one found in different places on Mendip Hills; and 3. A fine cream coloured one found only in the islands of the Archipelago. Of these containing heterogene particles we have nine species. 1. A bright coarse white one composed of crystal and spar found in Leicestershire. 2. A white coarse one with micæ common in Wales. 3. A dull white fine one found in Northamptonshire. 4. A dull greyish white coarse one common in Yorkshire. 5. A fine dull brownish white one common in Leicestershire. 6. A fine glittering greyish white one found in Yorkshire. 7. A fine greenish white spangled one found in Dorsetshire. 8. A dull coarse greenish grey one common in Yorkshire; and 9. The *pulvis puteolanus*, a fine dull looking grey one found in Italy. See PUTEOLANUS.

Red SABURRÆ. Of those which are pure we have five species. 1. A fine pale red one found in Bristol. 2. A coarse shining pale red one found on the coast of Fife. 3. A coarse shining greyish red one found on the shores of the island of Minorca. 4. A coarse greenish red dull one found on the shores of some parts of the Mediterranean. 5. A fine shining ferrugineous one found about Lisbon. Of those variegated with talcy spangles we have nine species. 1. A fine red one with micæ found about Minorca. 2. A coarse red variegated one with micæ. 3. A large bright flesh coloured one with micæ. 4. A fine brownish red variegated one with micæ. 5. A fine flesh coloured micaceous one, all from the coasts of Scotland. 6. A fine whitish red one with micæ, and variegations, found on the shores of the northern islands. 7. A brownish red coarse one found on the shores of the Red Sea. 8. A large coarse blackish red one found on the shores of Sicily; and 9. A coarse shining greenish red one found on the shores of the Mediterranean.

Green SABURRÆ. Of these we have only two known species. 1. A coarse beautifully green dull one, which was the chrysocolla of the antients, see CHRYSOCOLLA. And 2. A fine shining green one found on the shores of the Red Sea.

Yellow SABURRÆ. We yet know only one species of this kind, which is the shining gold coloured micaceous one, which has deceived the world very often into an opinion of its containing gold. It is very common in Virginia and elsewhere.

Black SABURRÆ. Of this we have one pure species, a fine black one variegated with white, common in France. Of those containing talcy particles we have two known species. 1. A fine variegated black and white one, with micæ found on the shores of the Mediterranean; and 2. A coarse variegated black and grey one, frequent on the shores of Wales; and besides these there are three of this colour which are full of metalline particles. 1. A ferrugineous black glittering one found on the shores of Italy. This is the shining black sand, as it is called, used to throw over writing. 2. A coarse glittering brownish black one, common on the shores of Wales, and used there on the same occasion; and 3. A fine bluish black glittering one, common also on the shores of Wales. All these are principally made up of lead ore. *Hill's* Hist of Foss. p. 569.

SACABURGH, SACABERE, or SAKEBERE, in our old writers, one that is robbed, or by theft deprived, of his money or goods, and puts in surety to prosecute the thief with fresh suit; according to Selden, in his titles of honour, and Briton. c. 15 & 29. with whom agrees Bracton (lib. 3. tract. 2. c. 32. n. 2.) *Furtum vero manifestum est, ubi latro deprehensus sit seisitus de aliquo latrocinio*, scil. Honhabend and

& Backberond & *inſecutus fuerit per aliquem cujus res illa fuerit, qui dicitur* ſacaburh, &c.

The word may come from the Saxon *ſac* or *ſaca*, i. e. *lis, cauſa, proſecutio*, and *burh*, *pignus*, *hoc eſt furti ſymbolum. Spelm.* Gloſſ. in voc.

But Sir Edward Coke ſays, *ſacabere*, or *ſakebere*, is derived from *ſac* and *bere*, that is, he that did bear the bag. 8 Inſt. fol. 69. *Blount.* Law Dict. in voc.

SACARII, among the Romans, were a company or fraternity of porters, who had the ſole privilege to carry all goods from the harbour to the warehouſes, none being allowed to employ their own ſlaves, and much leſs thoſe of others, for that purpoſe. *Pitiſc.* in voc.

SACCER. See the article SAKER, *Cycl.*

SACCHARUM (*Cycl.*)—SACCHARUM, in the Linnæan ſyſtem of botany, is the name of the plant which produces ſugar, and which makes a diſtinct genus by itſelf. The characters of this are, that there is no calyx or flower cup, but a downy ſubſtance longer than the flower, and including only one ſingle flower, which is compoſed of two oblong and pointed valves, both equal in ſize, placed erect, hollowed and naked, or not bearded. The ſtamina are three capillary filaments of the length of the flower; the antheræ are ſomewhat oblong, the germen of the piſtil is pointed. The ſtyles are two and are hairy, the ſtigmata are ſimple. The flower encloſes the ſeed which is ſingle, oblong, narrow, and pointed. *Linnæi* Gen. Pl. p. 18.

SACCHARUM *ſaturni*, in medicine, is recommended by ſome internally for dyſenteries, and hæmorrhages of all kinds; but the generality of the world condemn it, as containing all the poiſonous qualities of the metal it is made from in their higheſt degree.

Externally it has been long famous for its virtues in the eryſipelas, in inflammations of all kinds, and in embrocations. It is uſed alſo in ſmall quantities in collyriums for the eyes; it deterges, dries, and cicatriſes ulcers; and in gonorrhœas is mixed in injections with great ſucceſs.

It is well known that this ſalt made with the common vegetable or mineral acids, when diſtilled, will not give back the acid again, but only yields a water without any ſharp taſte and an inflammable oil; but if it be made into the animal acid of piſmires, whether procured by diſtilling thoſe inſects freſh, or by throwing large quantities of them into water till it is ſufficiently impregnated, it will on diſtillation yield back the ſame proportion of acid of the ſame ſtrength. Phil. Tranſ. N° 68. See TINCTURA *antiphthyſica*.

SACCHARUM *lactis*. See the article MILK.

SACCINI, in our old writers, Monks ſo called, becauſe they wore a garment of goat's hair next to their ſkins. *Saccus* is applied to coarſe cloth made of ſuch hair. *Blount.*

SACCO *beneditto*. See the article SANBENITO, *Cycl.*

SACCUS *cum brochia*, in our old writers, a ſervice or tenure of finding a *ſack* and a *broach* to the king, for the uſe of his army. Bract. lib. 2. c. 16. *Blount*, *Cowel.*

SACCUS *lacteus*, a name given by ſome anatomiſts to the *receptaculum chyli*.

SACER (*Cycl.*)—SACER, in ichthyology, a name given by Gaza and ſome others to that ſpecies of the *labrus*, diſtinguiſhed by Artedi by the name of the red forked tailed *labrus*, and called by the generality of other authors the *anthias piſcis*. See the article ANTHIAS.

SACHETTUS, in zoology, the name of a ſea fiſh, much reſembling the common river pearch in ſhape and colour, and having the ſame black obliquely tranſverſe lines on its ſides, and ſeeming the ſame with the *channadella* of Bellonius, Rondeletius, and other authors. It has only one long back fin, the foremoſt rays of which are prickly, the others ſmooth behind theſe prickly rays; it has a large black ſpot, which alone diſtinguiſhes this from all the other fiſh of its kind. Its mouth is large, and its lower jaw ſomething longer than its upper. The belly fins are black, and the tail is forked; the ſcales are large; and as in the other fiſh of this kind, cover not only the body but the gills, and part of the head of the fiſh. It is common in the Mediterranean, and is brought to market at Rome, Venice, and elſewhere, and accounted a very delicate and well taſted fiſh. *Ray*'s Ichthyolog. p. 326.

SACRA (*Cycl.*)—SACRA *fiſtula*, a name given by ſome to the cavity, in which the ſpinal marrow is lodged, and by others to the ſpinal marrow itſelf.

SACRA *gentilitia*, among the Romans. Beſide the public feſtivals obſerved by the whole Roman people, and beſide the holy-days kept on birth days, marriages, or any other perſonal account, there were likewiſe family feaſts celebrated annually by the deſcendants only of particular families.

They thought themſelves obliged to keep theſe with the utmoſt exactneſs and regularity, on pain of divine vengeance. Livy tells us that a young man of the Fabian family, when the capitol was beſieged by the Gauls, made his way through the enemy's army, in order to celebrate the yearly feſtival of his family, to the no ſmall aſtoniſhment both of the beſiegers and beſieged. Mem. Acad. Inſcript. Vol. 8. p. 310.

SACRANUS *color*, a name given by ſome authors to purple, or very deep red.

SACRARIUM, among the Romans, a chapel in a private family. It differed from *lararium*, as being dedicated to ſome particular deity, and the *lararium* to the houſhold gods in general. *Pitiſc.* in voc.

SACRE, in zoology, the name of a ſpecies of falcon, called by authors *falco ſacer*, and differently deſcribed by different authors, but by all agreed to be an extremely bold and active bird. The deſcription Mr. Ray has ſelected of it is this. It is a larger bird than the common falcon. Its head is flat and of a greyiſh colour; its eyes large, and its beak bluiſh. Its back and wings are brown; its breaſt white, and variegated with brown ſpots. Its thighs are white within, and its tail is variegated with ſpots of the ſhape of a kidney. Its wings are very long, and its legs and feet of a bluiſh colour. The yearling birds of this ſpecies are called *ſori*, and differ conſiderably in their plumage from thoſe of a more advanced age, having their legs paler, and their breaſts leſs ſpotted. It will ſeize upon the largeſt birds, and on young goats, &c. for food. *Ray*'s Ornithol. p. 43.

SACRIFICE (*Cycl.*)—SACRIFICES, among the Greeks, were of four kinds, *viz.* 1. Free-will offerings, or ſuch as were paid in conſequence of a vow, χαριστηρια and Ευκταια, for a victory obtained, the firſt fruits offered by huſbandmen for a plentiful harveſt, and the like. 2. Propitiatory offerings, ιλαστικα, to avert the anger of ſome offended deity, and ſuch were all *ſacrifices* uſed in expiation. 3. Petitionary ſacrifices, Αιτητικα, for ſucceſs in any enterprize. 4. *Sacrifices* expreſsly commanded by ſome oracle or prophet, τα απο μαντειας.

For the materials and rites of *ſacrifices* ſee *Potter*, Archæol. Græc. T. 1. p. 209. ſeqq. and SACRIFICE, *Cycl.*

SACRIMA, among the Romans, the new wine which was offered to Bacchus as an acknowledgment of his protecting and preſerving every thing that belonged to wine. *Pitiſc.*

SACRO-COCCYGÆUS, in anatomy, a name given by Winſlow to a muſcle now generally called ſimply the *coccygæus*, he calls it alſo *coccygæus poſterior*.

SACRO-LUMBARIS, a long complex muſcle, narrow and thin at the upper part, and broad and thick at the lower, repreſenting a kind of flat pyramid. It lies between the ſpine and poſterior part of all the ribs, and along the back part of the regio lumbaris, all the way to the os ſacrum. Through all this ſpace it is cloſely accompanied by the longiſſimus dorſi, which lies between it and the ſpinal apophyſes of the vertebræ, a narrow fatty or cellular line running between them; it is fixed below by a broad thin tendinous aponeuroſis to the os ſacrum, and part of the criſta of the os ilium. From thence it runs upward, and a little laterally over all the regio lumbaris; afterwards it runs up obliquely over all the ribs, ſometimes as high as the two or three loweſt vertebræ of the neck. The ſide next the longiſſimus dorſi is all this way very even; but that next the ribs is divided into ſeveral digitations, reſembling the branch of a palm tree. Theſe are fixed in the tranſverſe apophyſes of the neck, in the tuberoſity of the firſt rib, in the lower part of the angular impreſſions, in the following ribs, and near the extremity of the laſt. *Winſlow*'s Anatomy, p. 245.

SACRO-LUMBARIS *pars ſuperior*, in anatomy, a name given by Cowper and ſome others, to a muſcle, called by Winſlow *tranſverſalis collateralis colli*, and by Albinus the *cervicalis deſcendens*. See the article TRANSVERSALIS.

SACRO-SCIATIC *ligaments*. Theſe are two in number, the one broad and external, the other ſmall, narrow, and internal. The broad, or external *ſciatic* ligament, is ſlightly faſtened to the inſide of the tuberoſity of the criſta of the os ilium. It covers exteriorly the two poſterior ſpines of that bone, and continues to be inſerted along the anterior and exterior edges of the falſe tranſverſe apophyſes of the ſacrum. From thence this ligament diminiſhing in breadth, deſcends obliquely toward the tuberoſity of the os iſchium, and is inſerted immediately below the ſinus, which lies between that tuberoſity and the *ſciatic* ſpine. This inſertion is afterwards continued over the whole internal labium of the inferior portion of the os iſchium, and of the ramus of that bone, and the inferior portion of the ramus of the neighbouring os pubis. Through all this latter courſe of its inſertion, that is after its arrival at the tuberoſity of the iſchium, it produces a kind of ligamentary falx, one edge of which is fixed to the bones, the other lies looſe; and by this ſituation of the falx, it ſeems, together with the bones, a kind of deep channel or groove. The ſmall *ſacro-ſciatic*, or internal *ſciatic* ligament, adheres cloſely to the inſide of the poſterior portion of the former. It is fixed interiorly alſo to the edge of the inferior part of the fourth falſe tranſverſe apophyſis of the os ſacrum, and from thence all the way to the upper part of the os coccygis. From this inſertion it runs up a little obliquely to the ſpine of the iſchium, in the ſharp point and upper part of which it is fixed. During this courſe it croſſes the broad ligament, being cloſely united to the inſide thereof, and loſes but very little of its breadth. By theſe two ligaments two diſtinct openings are formed; a large one which is the ſuperior *ſciatic* ſinus, and a ſmall one with the inferior *ſciatic* notch. *Winſlow*'s Anatomy, p. 123.

SACRUM *os*. See the article Os *ſacrum*.

SACTIM, a word used by some of the chemical writers to express vitriol.

SADAF, in the materia medica, a name given by the Arabian writers, sometimes to the purpura or purple fish, and sometimes to the purple fucus, with which the antient Greek women used to stain their cheeks. This was the original of all painting, and the plant was the common purple sea wracks. After this every thing was called fucus that was used by the women to paint their faces; and they had a fucus metallica made of white lead or cerufs, and the purple root of alcanet, &c. were called fuci.

SADAR, or ALSADOR, the Arabian name of the medicinal *lotos*, described by Dioscorides, and many others of the antients. This shrub was called by some of the antients *acanthus*, from its being full of thorns, and hence many have confounded it with the common *acanthus*, or *bear's breech*, and many with the *acanthus* of Theophrastus, which is the acacia or gum arabic tree. The fruit of this tree, called by Virgil the berries of the *acanthus*, is the *nabac* of the Arabian writers, though some would have it to be a kind of fig. Serapion evidently declares the *sadar* and *acanthus* of Virgil, that is the *lotus cyreniaca* of Herodotus, and the *lotus* of Dioscorides to be one and the same plant. Bellonius has also described it under the name of *napeca*, a name probably derived from *nabac*, the appellation usually given its fruit: he says it is an ever-green shrub, and was called by some of the Greek writers *oenoplia*. Prosper Alpinus, in his account of the Ægyptian plants, also describes the *nabeca* as a thorny shrub; though authors have observed that there are two species of it, the one thorny and the other not. Leo Africanus, in his third book, mentions also the same tree; but he mistakes the name, writing it *rabech* instead of *nabech*; he says it is a prickly tree, producing a fruit resembling a cherry, but smaller, and of the taste of the zizyphus. These are the berries of the *acanthus* mentioned by Virgil. *Prosper Alpin.* de Plant. Ægypt.

SADDLE (*Cycl.*)—A hunting *saddle* is composed of two bows, two bands, fore-bolsters, pannels, and *saddle*-straps: and the great *saddle* has beside these parts, corks, hind-bolsters, and a troussequin. The pommel is common to both. See BOW, BAND, BOLSTER, &c.

A horseman that would sit a horse well, ought always to sit on his twist, and never on his buttocks, which ought never to touch the *saddle*; and whatever disorder the horse commits, he ought never to move above the *saddle*. *Guill.* Gent. Dict. P. I. in voc.

SADDLE-*backed*, among horsemen, a name given to a horse, that is hard to fit with a *saddle*, his reins being low, and his head and neck raised, so as to require a *saddle* to be made on purpose for him. *Guill.* loc. cit.

SADDLE *case*. See the article HOUSING, *Cycl.*

SADDLE *roll*. See the article TROUSSEQUIN, *Cycl.*

Cart-SADDLE. See the article CART.

SADDLE *straps*, are small leathern straps, nailed to the bows of the *saddle*, which are used to hold the girths fast to the *saddle*. See the article BOWS.

SADIR, a word used by some chemists to express the scoria of any metal in fusion.

SADRE, a title given by the Persians to the chief of the Mahometan religion. See the article CALIPH.

SÆPÆ, a name given by some medical writers to sharp corroding pustules.

SAFFRON, *crocus*, (*Cycl.*) in botany. See CROCUS.

There is no accident attending the culture of this valuable and useful plant, which the farmers so much dread, as what they call the *rot* with us, and in French *la mort*. This is more common in the *saffron* fields of the Gatinois than in ours. Mr. du Hamel, who undertook to give the Paris academy some account of this malady of the plant, observes, that no author has given any account of it; and that the people employed in the culture of the *saffron*, know the terrible effects of it, without at all guessing at what may be its cause. It seems a sort of contagion among the plants, spreading far and wide, and extending from one root as from a center all over a whole field, if not stopped; the season of its most fatal spreading is the spring, and the mischief is found to be stopped from farther progress, by digging deep trenches at that time of the year between the sound and the tainted parts of the field.

Mr. du Hamel, in enquiring into the state of the roots or bulbs of the *saffron* in many fields where this disorder reigned, found that the roots in the center where the distemperature most raged, and those at a middle distance from this part and the border of the field, and those at the border, were all in three different states, according to the degree of spreading of the infection. Those in the middle where the infection began, were utterly destroyed, their several coats all shrivelled up and withered, their inner part resembling only a dirty and rotten earth, and their superficies being covered with several brownish red glandulous bodies of the bigness of beans. Those of the middle distance were found in a condition nearly allied to these; their integuments were flaccid, but not wholly withered; and there were some remains of the fleshy bulb within; but this matter was a sort of pulp, looking as if it had been boiled. It was easy to see from this, that these roots were speedily approaching to the perfect state of decay of the others; they were covered in the same manner on their outsides with glandulous substances, like those of the middle roots, only that they seemed on these more plump, and well fed. At some distance from these he also observed a number of violet coloured threads, forming a sort of network in the ground.

The roots at the edges of the field were found in a yet much sounder state than any of the others; their bulbs seemed unhurt, and the membranes sound and fresh, but they were in many places covered with reticular violet coloured filaments, and from some parts of these there issued small glandules, which seemed ready to grow into the same shape and size with those on the decayed roots; though they, at this time, appeared only as so many purple spots lodged on the surface of the root or between its membranes. The earth all about these roots was also found to be full of these reticular violet coloured threads.

These violet threads and their glandules being always found in the places where the rot was among the *saffron* roots, and never in any other place, it became very natural to suppose they had some considerable share in the contagion; to examine, therefore, what they truly were, Mr. du Hamel picked several of them out of the earth, and having washed them clean, he found that they were very like the truffle in appearance; and in all their qualities they were seldom larger than a hazel nut, and were covered with a sort of soft down or velvety coat, and they had a mushroom like taste, but with an earthy flavour. There were found some of them adhering to the bulbs of the *saffron*, and others two or three inches distant from them; the violet threads are of the thickness of a coarse thread, and are covered with a velvety coat, in the same manner with the glandulous bodies; some of these extend themselves from one to another between these glandules, while others spread themselves over the surface of the bulb of the *saffron*, and pierced it in many directions quite to the center: they make numerous anastomoses and inosculations in the body of the root, and have fastened to them in several places little knots or ganglions, which seem only small tufts of the cottony or velvety matter which covers them.

From the whole it seems very clear, that this is a parasitical plant, which grows very quick in its glandules; and by means of these threads, or filaments, sucks its nutritious juices from the roots of the *saffron*, which it by that means destroys. It seems to grow in the same manner with the truffle, that is, it never appears above the surface of the earth, but is produced under ground, and there grows and propagates its species. It spreads very fast, and soon occupies a large compass of ground, continually furnishing new glandules at the end of the filamentous roots, in the manner of the potatoe and some other roots. Thus the disease of the *saffron*, wherever it begins, spreads itself every way in a circular direction; and there is nothing to be seen on the surface of the earth, which can give any opportunity of guessing at its cause.

It remained now to enquire whether this plant was peculiar to fields of *saffron*; and whether it was brought thither with the *saffron*, or was there before: and another material question was, whether it could draw its nourishment from any other plants, or must have it from *saffron* only. To try this, Mr. du Hamel put some of the bulbs of the new plant into a pot of fresh earth, where he also planted some roots of *saffron*, of narcissus, and of the common lilly. Six months afterwards, examining the whole, he found the glandules had greatly increased in number, and had fed upon the lilly roots as well as on the *saffron*; hence it appeared, that this was a real plant capable of increasing itself, and not destined singly to that food; after this digging up the earth in several places where *saffron* had never been planted, he found in some places the same parasitical plant, fastening itself to the roots of the anonis, and some other plants, and letting alone several others, such as the senecio, &c. The roots of muscari were also sometimes found affected by it; and a certain distemperature, which the florists complain of in their tulip roots, seems to be owing to the same cause.

This mischievous plant, however fatal it prove to the *saffron* fields; may, on the contrary, prove a real benefit in corn fields, by destroying many of the pernicious herbs which hurt the corn, as it preys only on those which send their roots deep into the earth, never hurting those which are superficially fixed, as corn, and the like are. The florist, however, is probably often as much injured by it, as the *saffron* cultivator; and doubtless, whole beds of plants are often destroyed without the proprietor's knowing what to attribute the mischief to. One misfortune attending this destroying plant, is, that the common culture of land which destroys other weeds, serves rather to promote its increase, since it delights in light dry earth, not in wet, or undug lands: it is possible, however, to stop its progress, by digging pretty deep between the sound and the infected roots; of the last, those which are eaten to the heart can never recover again, but of those which are only wounded superficially there is some hope; since it is common for them to be

be cured by taking them up, peeling off their outer husks, and drying them in the sun. This separates the worst part of the destructive plant, and the rest becomes soon dried and withered, and incapable of farther vegetation, while the root itself is uninjured, and when put into the ground will shoot again. Mem. Acad. Par. 1728.

The yellow tinge, which this medicine is able to give to the fluids, is carried so far, that no juice escapes it. Amatus Lusitanus gives an account of a fœtus in a mother's womb, tinged yellow, by her taking very frequently medicines with *saffron* in them. This had been disputed and disbelieved by many. But an experiment made at Leipsick on a bitch big with puppies, restored the credit of Amatus. For on giving this creature *saffron* frequently among her food, the puppies had their flesh and the whites of their eyes, when opened, dyed yellow with it; though the chyle, in the lacteals, was not yellow but whitish. However, it does not seem improper to verify the experiment farther.

Tree SAFFRON, in natural history, the name of an East-Indian shrub, which grows to about two feet high, having square branches, which are beset with leaves in pairs. The pedicles of the flowers come from the alæ of the leaves, and are branched, each pedicle supporting about five flowers; these are of the shape of the jasmine flowers, and are white above, and of the fine reddish yellow colour of *saffron* below. The flowers never open but in the night, and then do not perfectly expand themselves, but all the petals remain in such a position, that they can close instantaneously on occasion of the least heat; they are placed each in a green cup, to which they are so slightly fastened, that the least motion makes them fall. They seldom stand more than four days, often not so long; the flowers have no smell, but are of a cordial virtue, approaching to that of *saffron*. Mem. Acad. Paris, 1699.

Meadow SAFFRON, *colchicum*, in botany, the name of a genus of plants, the characters of which are these. The flower is of the liliaceous kind, but consists only of one leaf which arises immediately from the root, in form of a fine slender tube, and by degrees expands and enlarges, and becomes divided into six segments. The pistil arises from the bottom of the flower, and terminates in several very slender filaments; this finally becomes a fruit of an oblong trigonal form, which is divided into three cells, and contains roundish seeds. To this it is to be added, that the root is doubly tuberose, one part being fleshy, and the other tuberose, and both are covered with a common membrane.

The species of *colchicum* enumerated by Mr. Tournefort are these. 1. The common *colchicum*. 2. The white *colchicum* with purple lines. 3. The common *colchicum* with a leaf veined with white. 4. The common *colchicum* with a leaf painted with yellow. 5. The common French *colchicum* with single blackish purple flowers. 6. The *colchicum* which flowers both in spring and autumn. 7. The English narrow leaved white flowered *colchicum*. 8. The *colchicum* with flowers mottled with white and red. 9. The many flowering *colchicum*. 10. The white *colchicum* with red streaks. 11. The many flowered variegated *colchicum*. 12. The broad leaved variegated *colchicum*. 13. The *colchicum* variegated with a deep purple and snow white. 14. The *colchicum* variegated with a paler purple and a greyish white. 15. The *colchicum* with flowers, tessclated like the fritillaries. 16. The Coan purple *colchicum*, with large, broad, and curled deep green leaves. 17. The double Portugal *colchicum* with flesh coloured and purple flowers. 18. The *colchicum* with narrow variegated segments of the flower. 19. The double flowered variegated *colchicum*. 20. The many flowered, broad leaved, variegated *colchicum*. 21. The white many flowered *colchicum*. 22. The broad leaved many flowered *colchicum* with white hellebore leaves. 23. The double autumnal many flowered *colchicum*. 24. The vernal many flowered *colchicum* with broad convoluted leaves. 25. The double flowered common *colchicum*. 26. The many flowered double white *colchicum*. 27. The double many flowered *colchicum* with tessclated flowers. 28. The vernal Spanish *colchicum*; and 29. The narrow leaved mountain *colchicum*. *Tourn.* Inst. p. 349.

Syrup of SAFFRON. This medicine is thus made: take fine *saffron* an ounce, cut it small, and put it to infuse in a pint of mountain wine; let it stand three days without heat, then strain off the wine; to which, after filtration, add twenty-five ounces of double refined sugar: melt the sugar over a gentle heat, and then set it by for use.

Tincture of SAFFRON, a preparation made as follows: take *saffron* an ounce, cut it small, and pour on it in a matrass a pint of proof spirit; let them stand together three days without heat, often shaking the vessel, then filter off the tincture for use. Its dose is from thirty drops to a drachm or more. It is good in all cases where the *saffron* in substance is.

If the same quantity of wine be used instead of spirit, it is called *vinum crocatum*, *saffron* wine.

SAGADENON, a name given by the antients to what they say was the very finest kind of opobalsamum, produced in Palestine and the country thereabout.

SAGDA, or PSAGDA, in natural history, the name of a stone described by Aldrovand, which he says is of a green colour, and has the property of attracting wood.

Pliny and the antients give this name to a gem of a greenish colour, very much esteemed at that time; and about the origin of which the antients had many fabulous reports. Solinus tells us, that it is produced at the bottom of the sea, and thence rises up of itself as ships pass over the place where it is, and fixes itself to their bottoms, and that it cannot be got off again without cutting away a part of the wood. This author has generally taken his accounts of things from Pliny; though he has been at the pains to disguise them, in such a manner, that they are often unintelligible. All that Pliny says on this occasion, is, that the *sagda* was of a green colour, and was found by the Chaldæans at the bottoms of their ships; even this, however, is not very intelligible, unless they meant that the ships which traded to the Red Sea, and lay long in the harbours, and were sometimes aground, picked up at their bottoms the stones which make up the shores, and some of these are of the jasper kind, and usually green; at this rate it could not be a stone of any great value, nor do we indeed find any where that it was, except in Solinus.

It is to be observed, that the antients called a certain ointment by the name *sagda* as well as this stone; this ointment was green, and probably the stone had its name from the resembling it in colour. This was a custom common among the writers of early times; and they have the names of *libanotis*, *myrrhites*, *stactachates*, and *aromatites*, from the resemblance which certain agates and jaspers had to the drugs, &c. in common use among them.

SAGE, *salvia*, in botany. See SALVIA.

The several sorts of *sage* propagated either for the kitchen, or for medicine in our gardens, are to be produced by cuttings planted in any of the summer months, watering and shading them till they have taken root, and after that they should be removed to a dry soil, where they may have the benefit of the sun. *Miller's* Gardners Dict.

Sage has always been esteemed a cephalic and sudorific. An infusion of it made in the manner of tea, has been long famous as the common drink of people in fevers. It is attenuant and diuretic, promotes the menses, and is good in vertigoes, tremors, palsies, and catarrhs. There used to be a syrup, conserve, and simple water of *sage* kept in the shops; which are all disused, and the dried herb only retained.

SAGE *apples*, a name given by naturalists to a sort of soft gall, or protuberance, found frequently on the leaves and stalks of *sage* in the eastern parts of the world, and much resembling the soft gall of the oak leaf, called the *oak apple*.

These are both owing to the same cause, the puncture of an insect of the fly kind, which deposits its eggs in the wound, and the worms or maggots hatched from those eggs feed on the inside of the gall, and occasion a preternatural derivation of juices to the part, whence it swells and assumes this form. The leaves of many other plants are also liable to the same accident, particularly those of ground-ivy, on which there grow eatable galls of this kind. The *sage apples* are so frequent in the east, that they are brought to market at Constantinople, and eaten as delicacies. See GALLS.

SAGENE, a Russian measure equivalent to seven English feet. Five hundred *sagenes* make a werst. Phil. Transf. N° 445. Sect. 7. See WERST.

SAGIMEN *vitri*, a name given by some of the chemists to any alkaline salt.

SAGINA, in the Linnæan system of botany, the name of a genus of plants, the characters of which are these. The cup is a four leaved perianthium remaining after the flower is fallen; the leaves being of an oval figure, hollow, and spread very open. The flower is composed of four oval obtuse petals, shorter than the leaves of the cup, and spread wide open. The stamina are four capillary filaments, the antheræ are roundish. The germen of the pistil is of a globose figure; the styles are four in number, tapering in shape, and bent back; these are downy, and the stigmata are simple. The fruit is a capsule, of an oval figure, containing four cells, with four valves. The seeds are numerous and very small, and are fixed to the receptacle. *Linnæi* Gen. Pl. p. 55.

SAGITTARIUM *alexipharmacum*, in the materia medica, the name of a root cultivated with great care in Jamaica, and supposed a remedy for the wounds of poisonous arrows. The plant of which it is the root is the *canna indica radice alba*. *Sloan's* Hist. 1. p. 253. but its virtues have not yet brought it into use on this side the water. *Dale*, Pharm. p. 250.

SAGITTATED *leaf*, among botanists. See LEAF.

SAGOCHLAMYS, among the Romans, a sort of garment that partly resembled the *sagum* and partly the *chlamys*. See SAGUM and CHLAMYS, *Cycl. Pitisc.* in voc.

SAGOUIN, in zoology, the name of a very beautiful small species of monkey, described by Clusius, and seeming the same with *cogui minor* of Marggrave. See COGUI.

Clusius says it is of the size of a squirrel, and has the look

of a lion about the head, and that it is a very tender and delicate little animal, and impatient of the flighteft injury. *Ray's* Syn. Quad. p. 154.

SAGULUM, among the Romans, a little, or fhort *fagum*. See the article SAGUM, *Cycl.*

SAHIRA, in the materia medica, a name given by Avifenna to the *mify* of Diofcorides and the Greeks. Avifenna has placed it among the zagi or atramenta, but defcribes it in the very phrafe of Diofcorides, faying that it is of a gold yellow colour, hard and fparkling when broken. The Greek chemical writers call this *chalcanthum chloron*, or yellowifh vitriol. There feems, however, fome reafon to fufpect that Avifenna has, in this place, confounded two fubftances, and given to the melanteria the name of *fchira*, and the defcription of mify; for the mify has nothing in it to entitle it to the name of atramentum or ink; but the melanteria of the Greeks very well deferves that name, as it immediately turns black on being wetted, though it be in itfelf naturally of a yellow colour refembling fulphur. The properties of thefe two fubftances are ftrangely confounded by Avifenna; his interpreters are generally cenfured, as being faulty; but the blame, in reality, lies upon the author himfelf, who did not clearly underftand the things he was to defcribe to others. See the articles MELANTERIA and MISY.

SAIC, one of the many names given by the antients to quickfilver. See MERCURY, *Cycl.* and *Suppl.*

SAIL (*Cycl.*)—*After*-SAILS, in a fhip, are thofe that belong to the main maft and miffen. They keep the fhip to windward. On which account fhips failing on a quarter wind require a *head-fail* and an *after-fail*; one to countermand the other.

Netting-SAIL, in a fhip, is only a *fail* laid over the *Nettings*.

SAINT CUTHBERT's BEADS, an Englifh name for the *trochitæ* and *entrochi*, found in great abundance in the clay of Yorkfhire and fome other counties with us. They are truly the remains of parts of the arms of the *ftella arborefcens*, or branching *ftar-fifh*; but have been fo far miftaken, by authors, as to be fuppofed a fort of rock plants, or the parts of fome unknown vegetable petrified.

Agricola judged very well of the nature of the matter they confift of, faying they were of the fame fubftance with the *lapis judaicus*, which is a fpar, as they are, but thefe are ufually of a dufkier colour, fometimes bluifh, fometimes whitifh or reddifh, though thefe latter colours are more rare. The fame author obferves alfo, that they make an effervefcence with vinegar, and fome of them move out of their places with it, becoming a fort of creeping ftones. This is no great mark of diftinction, however, for all fpars, or all foffils, which vinegar will corode, will be acted upon, in the fame manner by it, provided that they are broke into fmall pieces, and that the bottom of the veffel in which the vinegar is put, be not too rough or too flanting to a point. The fingle joints are ufually thin, and regularly round; they have always a hole through the middle; though it is fometimes filled up with earthy or ftony matter; this has given them the name of *beads*, as by means of this they may be eafily ftrung together. The hole is ufually fmall, and fometimes oval, though commonly round.

The outermoft round or circle is generally fmooth, but the flat fides are all thick drawn with rays or lines from the circumference to the central hole. Aldrovandus from thefe ftriæ refembling antimony, and the whole mafs in the compound pieces, or *entrochi*, refembling the trunks of fmall trees, with the hollow for the pith, and the feeming rudiments of branches growing from them, calls them *ftelechitæ ftibii facie*. Though in other parts of his book he difcourfes of them after Gefner and Agricola, under the names of *trochitæ* and *entrochi*. In the compofition of the compound ftones or *entrochi*, the fingle joints are applied clofely to one another fide by fide, and they are fitted fo nicely together by the rays of one meeting the cavities between the rays of another, that the whole mafs, when ftruck violently, will not feparate into them, but breaks tranfverfely in an oblique direction, as all the other fpars do; particularly the *lapides judaici* or fpines of *echini* petrified. Phil. Tranf. N° 100.

SAINT FOIN, *fanum*, or *fanctum fœnum*, the name given by the French, and continued by us to a fpecies of plant, frequently ufed for the food of cattle, either frefh or dried; it is called *holy hay* or *wholefome hay*, from its excellent nutritive quality. The ftalks of the plant are commonly about two feet long, but they grow fometimes to five or fix feet, and it has tufts of red flowers of three, four, or five inches in length.

This plant will make a forty times greater increafe in poor ground than the common turf; and this is owing to its having a long perpendicular root, of that kind, called tap roots, which finks to a great depth to attract its nourifhment. The length of this root is fcarce to be credited by any but thofe who have feen it; it is frequently drawn out of the ground to the length of twelve or fourteen feet, but it is faid to be often thirty feet or more in length.

The farmers have a general opinion, that this plant never fucceeds well in any land, where there is not an under ftratum of ftone, chalk, or fome other hard matter, to ftop its running; but that otherwife it fpends itfelf in root, and comes to nothing above ground. This is an error too grofs to need much refutation. It is certain, that the roots being to plants, what the ftomach and guts are to animals, the more and larger roots any plant has, the more nourifhment it receives, and the better it thrives.

Saint foin always fucceeds where its roots run deep, and the beft crops of all are produced upon lands where there is no hard under foil to obftruct their paffage. An under foil of clay may kill the plants, by retaining the water, and chilling and rotting their roots.

The long root of *faint foin* has, near the furface, many horizontal roots iffuing from it, which extend themfelves every way; there are of the fame kind all the way down, as the roots go, but they grow fhorter and fhorter all the way. Any dry land may be made to produce this valuable and ufeful plant, though it be ever fo poor; but the richeft and beft land will produce the fineft crops of it. The beft way of fowing it is by drilling, but the earth muft be very well prepared, and the feed well ordered, or elfe very little of it will grow. The heads of thefe feeds are fo large, and their necks fo weak, that if they be much more than half an inch deep, they are not able to rife through the incumbent mould; and if they are not covered they will be malted, as the farmers exprefs it; that is, it will fend out its root while it lies above ground, and be killed by the air; and whether the farmer plants bad feed that will not grow, or good feed that is buried or malted, the event will be the fame. The ground will be underftocked with plants. A bufhel of feed to an acre of land is full twenty feeds to each fquare foot of land; but as there is fome difference in the largenefs of the feeds, there is no abfolute certainty as to this calculation. The worft feafons for planting it are the beginning of winter, and the drought of fummer; the beft is the beginning of the fpring; and it is always ftrongeft when planted alone, and is not fown together with corn, as is the practice of fome farmers. If barley, oats, or any other corn, fown with the *faint foin*, happen to be lodged afterwards, it kills the young *faint foin*. If it be planted with any other corn, it is beft done by drilling in the horfehoing way; in this cafe it is not much liable to be killed by the lodging of the corn, as the drilled corn feldom falls at all, and when it does, never falls fo low as the fown corn.

The quantity of feed to be drilled upon an acre of land will depend wholly upon the goodnefs of it; for there is fome feed of which not one in ten will ftrike, whereas in good feed not one in twenty will fail. The method of knowing the goodnefs, is, by fowing a certain number of the feeds, and feeing how many plants are produced by them. The external figns of the feed being good, are, that the hufk is of a bright colour, and the kernel plump, of a light grey or blue colour, and fometimes of a fhining black. The feed may be good though the hufk be black, as that is fometimes owing to the letting it receive the wet in the field, not to its being half rotted in the heap.

If the kernel be cut acrofs, and appear greenifh and frefh, it is a certain fign that it is good. If it be of a yellowifh colour, and friable, and look thin and pitted, they are bad figns. The quantity of feeds allowed to the acre in the drill way, is much lefs than that by fowing, and is to be computed according to the number of plants that are to be allowed in that fpace, allowing for the common cafualties. It is not neceffary to be exact in this calculation, or to fay whether two, three, or four hundred plants are to be allowed to a fquare perch; neither is it poffible to know before-hand the precife number of plants that may live out of thofe that come up; for fometimes the grub takes them when they have only the two firft leaves, and the crop is greatly diminifhed by this means. Four gallons of good feed to an acre of land will cover the land with plants when judicioufly managed.

Single plants of *faint foin* make the greateft crops; but the farmers, in general, plant them fo clofe, that they ftarve one another. The fingle plants always run the deepeft, and thofe which do fo will always draw moft nourifhment. The plants which ftand crowded ftarve one another, and often die after a few years; but the fingle ones grow to a vaft bignefs, and are every year better and better.

The beft way to calculate how many plants are to be allowed to a perch, is to compute how much hay each fingle large plant will produce; for if kept fingle, and well cultivated, they will all be large ones. Without culture thefe plants never arrive at a fourth part of the fize that they do with it. The hay of a large fingle cultivated plant will weigh more than half a pound, and a hundred and twelve plants upon a fquare perch, weighing but a quarter of a pound a piece, one with another, amount to two tun to an acre. If *faint foin* be planted on fome forts of land early in the fpring and hoed, it will fometimes produce a crop the following fummer; in a garden the feeds fown in February will yield plants of two feet high that will flower in the month

month of June following; and though March be frosty the young plants seldom suffer by it. This shews, that this plant is naturally a quick grower; but the farmers usually plant it on poor or cold land, and give it too little culture, which makes it backward, and slow of growth with them. The poor land usually allotted to this plant also makes it generally yield but one crop a year, but on a rich land it will yield two very good crops annually, with a moderate share of culture and management.

The farmer who expects to make a profit of this plant must not expect a good crop the first year. Nothing is so injurious to *saint foin* as its standing too thick; if it be sown so thick as to cover the ground the first summer, the plants will starve one another for ever after; but if the owner will be content to place them so thinly as to have but a small crop the first year, they will increase prodigiously, and every succeeding crop will be better and better. When *saint foin* is well hoed, it will grow as much in a fortnight as it would otherwise do in six weeks; and this quick growing is of advantage to it every way, not only making the plants larger, but of better nourishment to the cattle, whether they are eaten green or made into hay.

The proper distance to drill this plant for the horsehoing husbandry is at double rows, with eight inch partitions between them, and thirty inch intervals between every two and two. These intervals need only be hoed alternately, leaving every other interval for making the hay on. This method of hoing is of vast advantage, and poor land by means of it will always produce two crops in a year. The land is always to be perfectly cleared of grass before the sowing the *saint foin*, and the lumps of earth carefully broken. But no harrowing is to be allowed after it is drilled, for that would bury it; and it is not proper to roll it at all, unless for the sake of barley, when they are sown together; and when that is done, it should be with a light roller and in dry weather. This should be done lengthwise of the rows, and as soon as it is drilled; if it be not done at this time, it is best to stay three weeks before it is done, that the necks of the young *saint foin* may not be broken.

No cattle are to be suffered to come in the first winter upon the *saint foin*, after the corn is cut, among which it was sown. Their feet would injure it by treading the ground hard, as much as their mouths, by cropping it, and it would never come to good. Sheep should not be suffered to come at it even the following summer and winter. One acre of drilled *saint foin*, considering the difference of the quantity and goodness of the crop, is worth two acres of sown *saint foin* on the same land, though the expence of drilling be twenty times less than that of sowing. The first winter is the time to lay on manure after the corn is reaped off. Pot-ashes, or the like, are very proper, and a small quantity of them will do, as there are at this time no other plants to partake of the benefit, but the young crop has it all; and the young plants being thus made strong at first, will continue so, and be long the better for it.

It is observed, however, that in the drilling and horsehoing way there is no necessity for any manure at all. Some farmers sow eight or ten bushels of the seed of *saint foin* to an acre along with their corn, with intent that it should kill all the other weeds; but the consequence is, that the plants stand close, and starve one another, and are no bigger than where the plant grows wild on the hills in Calabria, where it is so small and seemingly despicable a plant, that it seems a wonder that any body could be tempted to think of cultivating it: yet, when rightly managed, it seems capable of being as useful a plant as any in the world. Where these plants stand so thick they draw out all the nourishment from the ground, in a few first years, and soon die, though manured ever so carefully. Six or seven years seems their greatest duration; whereas, when the seed is drilled in, and the plants are horsehoed, they will be as strong and vigorous as ever, at thirty years standing.

Some people who have turned their thoughts to husbandry, have been of opinion, that the cytisus would succeed better with us than the *saint foin*; it is probable enough that it would grow well; but the labour of sheering it, would with us, where the pay of servants is so dear, run away with the greatest part of the profits of the crop.

Lucerne is another thing which many have thought of introducing among us in the place of *saint foin*, but it requires so much care to suit it with a proper soil, that whatever are the profits of it, it never can be so general as *saint foin*. *Tull's* Horsehoing Husbandry, p. 76. seq.

Saint foin succeeds best also in high grounds, which is a great advantage in the article of making it into hay, as it has greatly more advantage of the sun, and less to fear of mischief from wet than grass which grows in low grounds. On the high grounds the wind will dry more in an hour than it will in meadows that lie low in a whole day; and often the crops of *saint foin* make very good hay in the same seasons in which all the grass hay is utterly spoiled. The sun, on the high grounds, has also a more benign influence, and sends off the dew there two hours earlier in the morning, and holds it up as much longer in the evening; by these advantages the *saint foin* has more time to dry, and is made with half the expence of common hay.

All kinds of hay differ greatly in their goodness, according to the manner in which they are made, but the hay of *saint foin* differs more than all.

There are properly four kinds of the *saint foin* hay, differing according to the times of cutting them. These are first, the virgin hay; secondly, the blossomed hay; thirdly, the full grown hay; and fourthly, the thrashed hay. The first of these, or virgin hay of *saint foin*, is the best of all, and excepting lucerne has not its equal in the world. The *saint foin* for this hay must be cut before it begins to blossom; for when it stands till full blown, the most volatile spirituous and nutritive parts of its juices are spent on the generation; and this being done at once, the sap is greatly depauperated, and the plant can never afterwards recover the strength, vigour, and nutritive qualities it had at that time. The exact time of cutting this is, when a few of the blossoms, which are forwarder than the rest, are beginning to look red. *Saint foin* cut in this state, even though the weather prove bad, may be made up in small ricks, and a chaff basket drawn in the middle of each; this easy care will prevent it from firing; and though the colour be a little altered, it will be as good and nourishing, as if made at the most favourable season. Working stone-horses have been kept fat the whole winter on this hay alone without corn, and they are so fond of it that they will refuse beans and oats mixed with chaff in the common way for it.

Sheep will also be fatted in pens in winter with only this hay and water better than with pease, oats, and the like; and if the hay be weighed to them, and the whole expence and profit computed, the clear profit will be found to amount to four pounds a tun. These creatures make no waste in this way of feeding, but eat up every morsel of the stalks, though ever so thick, for they are always brittle, and are as well tasted as the rest.

The blossom hay is very beautiful to the eye, and of a very sweet smell, but it does not fatten the sheep as the virgin hay does, nor can working horses be kept fat upon this without an admixture of some corn.

The land ought to be well tilled for the virgin hay; for if it stand on a poor land, without much culture, it will not be above four or five inches long before it flowers, and will therefore yield but a poor quantity, and will spring up again, but very slowly, for another crop; but when on good land and well tilled, it will yield at this time two or three tun to an acre, and will spring up immediately very strong for a second crop.

This virgin hay is seldom sold, it being worth a much greater price than the common, and being usually kept by the farmer for his own use. Id. Ibid.

Beside the advantage the farmer makes of this plant, as well for hay as for the feeding his cattle, there is a considerable profit to be made by selling the seed of it when properly managed.

The owner of a land of *saint foin* has three chances for the making his hay; since this may be done either when it is in the leaf, or in the bloom, or when full grown. If the weather should prove unfavourable all this time, he may still reserve the crop for seed, and for thrashed hay, to his no small advantage. The ordinary crop of seed from one acre is sufficient to plant a hundred acres in the way of horsehoing husbandry; but as this is not yet universally practised, there is a sufficient demand for what seed a few who practise it can spare.

But beside the use of *saint foin* seed in sowing for new crops, it is also an excellent provender for horses; and those, in general, who have tried it, affirm, that one bushel of it will go as far as a bushel and a quarter of oats. When this seed is well cured, it is extremely sweet, and all sorts of cattle are fond of it: hogs will eat it and be fattened very well by it. But the goodness of the seed, and of the remaining hay, from out of which it is thrashed, depends very much upon the manner of the managing of them. When the thrashed hay has been kept dry, it is found to be better food for horses than common grass hay; and when cut small with an engine it is found as good as chaff for any cattle. It requires some skill to know the time at which the *saint foin* should be cut for seed. The seeds never ripen all at once. The flowers grow in spikes, and begin opening at the bottom, from thence gradually opening to the top. It is several days before the whole succession of flowers are blown, and the seed ripens in the same manner, so that the lower part of the ear has ripe seed many days before the top; and, in consequence, if the farmer stays till the top seeds are quite ripe, the lower ones will be all shed and lost.

The properest time to cut it is when the greatest part of the seed is ripe, the top part beginning to be full and the bottom full ripe. The kernel or seed is bluish, and the husk brownish when ripe. The seeds and husks are green for some time after the flowers are fallen, and it is better to cut the plant while it is thus, than to let it stand too long; for the

the seeds will ripen and become bluish after cutting, which will be much better than the letting them be lost by waiting till they ripen upon the stalks in bad weather.

The *saint foin* for seed must never be cut in the heat of the day, for then it will dry too fast as it falls, and much of the seed will be lost. It is best for the mowers to begin at day-break, and to leave off as soon as the sun has any power, going to work again in the cool of the evening. If the plant be dry at the time of cutting, it may be immediately made up into little cocks; but if not, it must be made hay of, only observing never to turn it while the sun is hot upon it: unless there happen rain it is scarce necessary to turn the swarths at all; and when this is done, it must be done very carefully, that the ears be not shaken.

There are two ways of thrashing this plant; the one on the field, the other in the barn. The first can only be done in very fine weather, and while the sun shines warmly upon the field. The middle of the day is the only time for this, and the method is to spread a large sheet, and peg it down at the corners, and in this thrash the plants from the cocks by small parcels at a time. The straw is to be separated from the seed, and made up into ricks; and this is good food for horses and other cattle, and the seed, *&c.* is to be collected, and afterwards winnowed, to separate the chaff.

If the seed have been wetted in the time of thrashing or lying in the ear, it may be put up immediately; but if it have been thrashed and winnowed dry, it will ferment and spoil if laid together too soon. The common way of managing it is by spreading it in a malt-house, or on a barn floor, but in spite of this it will often heat and spoil; the best way of all is to spread a layer of straw, and on this sprinkle a layer of the seeds, then cover these with another layer of straw, and this with more seeds, and so on, till the heap is raised six or seven feet high. The seed will thus be kept cool, and in spring it may be easily separated from the straw, and will be as fresh as if just thrashed; if this be sown, not one seed in twenty will fail of coming up. When the weather is not fine enough to give opportunity to the thrashing the *saint foin* in the field, it must be very carefully carried into the barn with sheets at the bottom of the carts, otherwise a great quantity of the seed will be lost in the way. *Tull*'s Husbandry, p. 90.

SAKER, in the manege, the same with *dock*. See DOCK.

SAL, *salt* (*Cycl.*)—See the article SALT.

SAL, in the history of the gems, a term used by Pliny and the antients, to signify a defect or flaw, which took off very much from the value of the gem. Martial having occasion to mention this sort of blemish, in crystal, calls it *nitrum* instead of *sal*. *Et turbata levi questus crystallina nitro.*

The critics have sometimes changed this word *nitro*, to *vitro*, and others have made the confusion yet greater, by supposing that the poet did not mean rock crystal but crystalline glass: but these are all errors. It is plain, by what Pliny and others have said on the same subject, that the author means here the same that others do by the word *sal*. This was a dusky and dusty foulness, seemingly composed of a quantity of saline particles, shooting into their forms within the body of the crystal. The gems in general were subject to this blemish; and we find, in particular, that the emerald was frequently debased by it.

It is found at this time, indeed, that crystal is much more subject to it than any of the gems; but, as the Romans called all the green crystals found in the copper mines of Cyprus by the name of emeralds, it is easy to conceive, that the emerald, as they understood the word, must be frequently subject to it. The poets using the word *nitrum* instead of *sal* is not wonderful, for the Greeks called common salt *halonitrum*, so that the words seem almost synonymous.

SAL *Ægypti*, in natural history, a name given by Hippocrates, and many other of the old writers, to the *natrum* of the antients, called also *nitrum* by some, though very different from our nitre. It had the name *natrum* from *natrium*, or *nitrium*, the name of a city of Ægypt; and therefore this, as well as the name used by Hippocrates, stood for Egyptian salt.

SAL *ammoniac*, or *armoniac*. See ARMONIAC, *Cycl.*

The substance known by the antients, under this denomination, was very different from the *salt* we now call by this name. It was indeed no other than a particular appearance of the *muria*, or common alimentary *salt*, in a striated form. We have common *salt* of this very form now in some parts of the world, but though with us it is scarce, with them it was very frequent, and was in common use, and esteemed the very best kind of *salt* for the use of the table. Dioscorides is extremely accurate and express in his account of it, and when he has reckoned up the various properties and uses of common *salt*, he describes the several sorts of it, and particularly this striated one among them, which, he says, was the very best of all the kinds; yet it seems owing to the description of this author, that the common errors about this *salt* have arisen; for he says that it was fossile, and composed of strait regular fibres. And after writers finding no *salt* of the common alimentary kind, answering to these characters, and perceiving that the compound mass, we call *sal armoniac*, was of this structure and appearance, made no hesitation to determine this to be the *salt* called *sal ammoniacum* by the antients, not considering the incongruity of the characters of that *salt* to their accounts, or the impossibility of its ever being used at table as common *salt*. *Hill*'s Hist. of Foss. p. 384.

The *sal ammoniac* of the moderns may be easily prepared in the following manner: take four ounces of common volatile *salt* of ox bone, saturate it with strong spirit of sea *salt*, and evaporate the superfluous moisture, upon which there will be found a cake of true *sal armoniac* left behind.

This is an experiment which regards both philosophical and technical chemistry, as it shews that odours may depend upon the mechanical structure and texture of bodies; and leads to a cheap way of making *sal armoniac* in other countries, as well as in the Levant. The volatile *salt* here employed has a very quick and pungent odour; so likewise, though in a less degree, has the spirit of *salt*; but these two, upon mixing, destroy each other's odour, so as to leave the cake of *sal armoniac* scentless; but if a little of this *sal armoniac* be rubbed in a mortar with salt of tartar, or any other fixed alkali, this lays hold of the acid of the sea *salt*, and leaves the volatile salt to strike the nose as pungently as before. *Shaw*'s Lectures, p. 422.

Our own volcanos, or subterraneous fires, which we have in the coal countries, afford us *sal ammoniac*. It is found sticking to the sides of the openings of these volcanos, in considerable thick crusts, under other crusts of sublimed sulphur. There is no fossile *salt* in these places, nor any thing else, that can form *sal armoniac* in the common way we suppose it to be found in; but it appears truly, that it proceeds only from the coal that feeds these fires. It is certain, that *sal armoniac* is sometimes found on brick kilns, where nothing but coals and common brick clay are burnt; and as no one would suspect it of being contained in the brick clay, there is here only the coal to afford it. The common coal slate of those counties also contains alum, sulphur, and *sal armoniac*; for alum may be drawn from it by the common operations; and when it is burnt, as it frequently is there for hardening the coal ways, both brimstone and *sal armoniac* are found in the heaps in several places.

The *sal armoniac* found in the openings of the burning mountains, particularly mount Ætna, is evidently the same in all respects with ours; and even this also may, for ought we know, be formed of coals, of which the inaccessible bowels of that mountain may contain great stores; though none have been found rising near enough to the surface to be dug for use. Other bitumens also may possibly afford this *salt* on burning as well as coal, and it is not to be doubted but many such are to be found in the earth thereabouts. The *salt* on the sides of the mouths of mount Ætna is found in large and thick cakes, and in dry weather may be collected in vast quantities, and possibly a great part of what the Venetians sell into other parts of Europe may be from these places. Either this *salt*, or that of our own volcanos, may be used in all the processes of chemistry, with the same success as other *sal armoniac*. It is of itself grey and coarse, but on mixing it with lime, and wetting them, a volatile spirit is raised; and on subliming a mixture of it with pot-ash, a dry and white volatile *salt* is obtained. If some spirit of wine be added to the mixture of *sal armoniac* and pot-ash, more of the volatile *salt* will be produced than any other way. Phil. Transf. Nº 130.

We are well assured that this *salt* is a concrete, the acid of which is that of sea *salt*, and its alkali, a volatile urinous one; both of which are found in dung burnt and raised into soot.

If there is occasion to separate the acid of sea *salt* from *sal ammoniac*, there need only be used the common vitriolic acid, which being well known to be stronger than that of sea *salt*, it divests that acid of its alkali by its superior power, and it becomes the basis of a new concrete *salt* with this acid, while the acid of sea *salt* now freed and separated may be drawn off pure by distillation.

If on the other hand it were required to draw from *sal ammoniac* its volatile alkali, the substances to be employed to this purpose are such alkalies as act upon the acid of the sea *salt*, absorbing and retaining it; the volatile alkali becomes freed, and rises with a very small heat. This alkali thus raised appears in two different forms, the one a liquid, which is called spirit of *sal ammoniac*, the other a dry one, which is called the sublimed *salt* of *sal ammoniac*; and though these are sometimes obtained separate, yet in some operations they are in part of the one and in part of the other kind. This is well explained by Mr. du Hamel in his course of experiments on this substance. Mem. Acad. Scien. Par. 1735.

As the adding an alkali is the way to separate this natural volatile alkali from *sal ammoniac*, the more powerful that added alkali is, the better may it be expected to perform its effect. Chalk, lime, *salt* of tartar, and pot-ashes, have all been in common use to this purpose, and all except the lime give the volatile alkali in a dry form, which is no wonder, since these are all naturally dry bodies before the operation; but there is one circumstance in these operations very worthy regard,

regard, which is, that the mixtures ſometimes afford more volatile alkali than the weight of the whole quantity of *ſal ammoniac* from which this volatile alkali is drawn; beſide that, there muſt be ſuppoſed to remain all the acid matter at the bottom of the veſſel; but the whole account of this muſt be, that this volatile urinous *ſalt* is ſo extremely powerful, that it raiſes and carries up with it a part of its other matter.

It remains, however, yet to enquire why lime alone being joined with *ſal ammoniac* in diſtillation, yields this volatile alkali in a liquid form, or in the ſtate of ſpirit of *ſal ammoniac*. There ſeldom riſes any thing in a dry form in this proceſs; when there does it is but very little; and when there ariſes no liquid, as is ſometimes the caſe, there ariſes often nothing at all; whereas, with the other alkalies, there ariſes, as has been ſeen, more than the weight of the whole quantity of *ſal ammoniac*. We very well know that this liquid ſubſtance, which we call ſpirit, is no other than the ſame volatile *ſalt* diſſolved in water, or in ſome other humidity, furniſhed by the matter, added to the ſalt in the diſtillation, and that this *ſalt* in riſing has brought up its diſſolvent with it. The lime, though deprived in a great degree of its humidity, by the operation which made it lime, yet retains enough for the purpoſe of melting the *ſalt* into what we call this ſpirit; and when the operation with lime does not ſucceed it is owing to this, that the calcination of the lime has been ſo perfect, as to deprive it of all its humidity; and the truth of this is evident, ſince the adding a little water will always enſure the riſing of a ſufficient quantity of ſpirit, and that with leſs fire than it can be obtained with when no water is added. We are yet at a loſs, however, to account for lime's acting differently from all the other additions to this *ſalt*, and making nothing ariſe in a dry form.

Mr. du Hamel obſerves, that by its formation, lime is diveſted of all acids, and of all humidity; but that by means of its fatty particles, whether they are from ſhells embodied in the ſtones from which it was made, or from the natural bitumen of ſtones, it is always endeavouring to recover what it has been diveſted of by fire; that it abounds with a vaſt number of fiery particles; and that by means of theſe, it is enabled to act upon the urinous, and therefore fatty matter of the *ſal ammoniac*; whether it be, that it unites itſelf intimately with it, ſo as never to be ſeparated from it, or whether it decompounds, and as it were burns it. And what confirms this conjecture, is, that Mr. du Hamel having diſtilled four drachms of ſpirit of *ſal ammoniac* with one drachm of freſh lime, he obtained a ſmall quantity of volatile *ſalt* in a dry form; the lime in ſo ſmall a proportion not being able to prevent the *ſalt* from this ſpirit from appearing in a dry form. And it is eaſy to conclude hence, that a volatile *ſalt* might be obtained from *ſal ammoniac* with lime, in a dry form, provided that the *ſal ammoniac* be mixed in an over proportion up to a certain quantity. Mem. Acad. Scien. Par. 1735.

The ſpirit and *ſalt* of *ſal ammoniac* being the ſame matter in a dry and a liquid form; it is evident, that the liquid muſt of the two be moſt ſtriking to the noſe, becauſe the particles of the *ſalt* are more eaſily diſunited from this latter union: and the *ſalt*, in a dry form, is ſo very volatile, that it entirely evaporates when laid on a hot iron, however fixed the matter may have been, which it originally carried up with it. It appears very plain from this, that the union between this volatile body and the particles of more fixed ones, which it carries up with it in ſublimation, and which are proper to give it the form of a dry concrete, is ſo intimate, that it will bear very ſevere trials and remain unaltered, and indeed, that it is ſcarce poſſible at all to decompoſe it.

It is no indifferent matter what the additions are with which *ſal ammoniac* is diſtilled; they muſt, by no means, be either ſuch as contain a nitrous, or a vitriolic acid; the former of theſe meeting with the fatty and ſulphurous part of the *ſal ammoniac*, may cauſe a detonation and burſt the veſſels; and the other, which is yet much more dangerous, might diſengage a portion of the ſea *ſalt*, which would again mix with the volatile part with which it has now no buſineſs to be allied, and with the fatty matter it might form a very diſagreeably ſcented ſulphur. Bole contains a vitriolic acid, and is therefore to be rejected. Gypſum mixed with it gives a ſmoaking liquor, whoſe odour is inſupportable, and chalk and common pot-aſhes are the beſt of all additions.

The firſt who gave *ſal ammoniac* internally was Platerus; but its uſe in fevers was not then known; he only uſing it in aſthmas. In ſucceeding times it became known as a febrifuge. It is frequently uſed in this intention, in Germany and Holland, and with great ſucceſs. The common doſe to a grown perſon is one drachm. The largeſt doſe, in caſes of the moſt robuſt conſtitutions, is two drachms. A perſon of eleven or twelve years old may take two ſcruples, and an infant of a year old may take fourteen grains. Its chief virtue is in intermittent fevers, in which it may be thus given. Let the doſe of *ſal ammoniac*, proportioned to the age and ſtrength of the patient, be diſſolved in an ounce of common water, or of any diſtilled water; and let the patient take it half an hour before the time that the fit is to come on. This is to be repeated in the ſame manner, before every fit, till the diſtemper is removed.

Though the great uſe of this medicine be in intermitting fevers; it is not, however, adapted only to thoſe, but may be of uſe in fevers of other kinds. The ſame doſe may be taken every five or ſix hours, drinking a baſon of ſage tea after it. It very frequently ſucceeds ſo well, that one doſe of it carries off the diſeaſe, ſo that it never returns again; but if the firſt doſe does not ſucceed in this manner a few others will. Two, three, or four doſes almoſt always prove ſufficient. This medicine has no viſible effect upon the body, more than the ſudden removal of the ſickneſs; for it neither operates by vomit, nor by ſtool, nor by ſweat: its effect ſeems to be owing to the correcting and altering of the matter of the diſeaſe, not the evacuating it out of the body.

The bark is ſuperior to this *ſalt* in the cures of quartan agues, and indeed in other caſes it is more certain in the ſtopping a ſecond fit; but there is another advantage in this, which the bark greatly wants, this is the preventing relapſes. Theſe are very frequent after cures in the common way, but are ſcarce ever found to follow in caſes when this *ſalt* has been uſed.

Another advantage of this medicine is the ſmall quantity of the doſe, and the few doſes that are neceſſary to be taken for a cure; whereas every one knows how many large doſes of the bark are neceſſary, and that often at ſuch ſmall diſtances of time, in caſes, that it is often difficult to perſuade the patient to be cured at the expence of ſo nauſeous a load of medicines. Act. Erudit. 1717.

SAL *aquarum*, in natural hiſtory, a name given by many of the antient writers to the nitre of the antients or *natrum*.

They had this *ſalt* principally from Ægypt, and called it in their works the produce of the evaporated waters of the Nile; for this reaſon Hippocrates ſometimes calls it *ſal ægypti*, and ſometimes *ſal in aquis creſcens*, a *ſalt* growing in the waters.

SAL *circulatum*, in chemiſtry, a term uſed by Paracelſus for a preparation of ſea *ſalt*, of which he diſtinguiſhes two kinds, under the name of the *circulatum minus* and *circulatum majus*. Theſe ſeem to have a great affinity with the famous alkaheſt or univerſal ſolvent, ſo much talked of in the works of this author, and his ſucceſſor Van Helmont.

The *circulatum minus* was a liquor procured by a tedious proceſs from ſea *ſalt*; this *ſalt*, he ſays, is that body in which nature has placed the greateſt perfection; and from this he, by incredible induſtry, procured a liquor which he calls a perpetual oil, and to which he alſo gives the name of the ens primum of *ſalts*. He calls it the higheſt and moſt ſucceſsful of all *ſalts*, and declares that all poiſons are ſubdued by it; and that being brought to the utmoſt degree of purity and ſubtilty, it pervades all bodies, and readily diſſolves them, itſelf remaining unaltered in the action. Theſe are all properties expreſsly attributed by Helmont to the famous alkaheſt. See ALKAHEST.

The *circulatum majus*, however, we are told, by the ſame author, was much more powerful and much more difficult to be obtained than the former. This he calls the matter of mercurial *ſalt*, and the living fire: he acknowledges that the higheſt fire and celeſtial life lie hid in common mercury, and ſays the quinteſſence of mercury is celeſtial fire: by this and a great many other enigmatic expreſſions in this writer, there is room to believe, that the alkaheſt, deſcribed by Helmont, is a preparation of mercury and ſea *ſalts*. *Boerh.* Chem. p. 573.

SAL *diureticus*, a form of medicine, of the nature of the *terra foliata tartari*, introduced into practice by the late college diſpenſatory. The method of preparing it is this: take of any alkaline fixed *ſalt* a pound, boil it in four or five pints of diſtilled vinegar in a gentle heat. When the fermentation is over, pour on more diſtilled vinegar; and when the fermentation ariſing from this addition is over, pour on ſtill more, and proceed thus till the moiſture being nearly all evaporated, freſh vinegar being added will excite no more fermentation: this generally happens when about ten quarts have been uſed; then evaporate to a dryneſs; the *ſalt* will be impure, and muſt be melted for a ſmall time, with a gentle heat, afterwards diſſolved in water, and filtered; if the melting has been rightly performed, the ſtrained liquor will be pellucid as water; then evaporate this in a gentle heat to a dryneſs, and you will have a very white *ſalt*, ſoluble either in water or ſpirit of wine. *Pemberton*'s Lond. Diſp. p. 187.

Jamblici SAL. See the article JAMBLICI *ſal*.

SAL *lucidum*, in natural hiſtory, a name given by ſome to nitre. Others uſe the phraſe to expreſs the nitre of the antients, that is the natrum.

SAL *marinus*, in ichthyography, the name of a truttaceous fiſh of the umbla kind, and very much approaching to that ſpecies called the *reutele*. See REUTELE. And by ſome ſuſpected not to be eſſentially different from that ſpecies. It is a very ſcarce fiſh, and is extremely valued for the table, but is never caught in any plenty, never keeping in ſhoals as many other fiſhes, but living ſingly. It loves clear ſtony rivers of a ſharp current, and feeds on ſmall fiſh. Its moſt frequent ſize is of about a pound weight, and it very rarely exceeds

exceeds twice that. Its tail and fins are very red; its fides and belly reddifh, and its back of a fort of orange colour or reddifh yellow, having fome yellow fpots. Its fcales are moderately large, and do not eafily fall off on rubbing.

The *fal marinus* is diftinguifhed by Artedi by the name of the forked tailed falmon, with a yellowifh back, and with yellow fpots. See SALMO.

SAL *marinum regeneratum*, in chemiftry, the name given to a fea *falt*, produced by adding an alkali to its acid fpirit of *falt* drawn by diftillation. The procefs is thus, dilute four ounces of oil of tartar, with three times its weight of fair water; put this mixture into a tall glafs body, and heat it, and drop into it any of the kinds of fpirit of fea *falt*, whether Glauber's, or that prepared with bole; fhake the veffel now and then, and continue to drop in the acid till the alkaline liquor is fated, and there rifes no more effervefcence; filter the liquor, and evaporate to a pellicle, and fet it by to cryftallize, and there will be procured cryftals of perfect fea *falt*, in all things agreeing with common *falt*. *Boerh.* Chem. Part II. p. 253.

SAL *martis*, *falt of iron*, a chemical preparation, which is made as follows: mix together a quart of water and eight ounces of oil of vitriol; pour the oil of vitriol in by a little at a time; and having put this mixture into a glafs veffel, add to it filings of iron, four ounces. When the ebullition is over, evaporate the liquor to a pellicle, and fet it to fhoot; there will be found a green vitriol or *falt* in fair cryftals, which dry for ufe.

This *falt* is one of the moft powerful preparations of iron; it opens obftructions of all kinds, and ftrengthens the vifcera; it is an excellent medicine in cachexies, obftructions of the fpleen and liver, and in fuppreffions of the menfes; it is alfo found good againft worms.

The beft manner of giving it is in folution, half an ounce in a quart of water, four ounces of which is a dofe; and if drank in the manner of the natural chalybeate waters, it will be found to exceed moft of them in its good effects.

SAL *mirabile*. *Glauber's falts*. Though this be a well known preparation, and the refult of a mixture of a vitriolic acid with marine *falt*, and the world has fuppofed it could be no other way found than by fuch an union made by art; yet Mr. Heliot has communicated to the academy of fciences of Paris, an account of its being found in vitriol alone, without the addition of any foreign matter.

The common green vitriol or copperas is well known to be made in England, by an union of the fulphureous acid of the common pyrites, and iron. Old iron is thrown into large quantities of a folution of the pyrites, that it may be diffolved, and the union produces a concrete in the form of a regular *falt*. This *falt* we well know contains a fulphureous matter; whether that be obtained from the pyrites, or from the iron that enters its compofition; fince, in the diftillation of its oil, there ever efcapes a very ftrong and penetrating fcent of fulphur through the junctures of the veffels.

There are alfo fome vitriols, particularly the common Swedifh kind, which may very probably be aluminous; fince the yellow fhining gold like marcafite from which it is made, yields in its native ftate true fulphur in diftillation, and afterwards affords vitriol in the lixivium, after the remainder has been long expofed to the air, and finally it yields alfo alum by the addition of urine and pot-afhes, to what they call the mother water of vitriol.

Mr. Lemery has fhewn, that after a moderate diftillation of green vitriol, a *falt* of the nature of alum may be drawn by a lixivium from the colcothar; and befide this, Mr. Heliot has found in that colcothar a vitrifiable earth, and a genuine *Glauber's falt*. Thofe who are at all acquainted with chemiftry, know that *Glauber's falt* is a concrete compofed of the vitriolic acid and fea *falt*, and it is generally received as a certainty that any other acid joined to fea *falt* cannot afford this concrete; therefore if *Glauber's falt* is to be produced from fea falt alone, and yet is proved to be found in pure vitriol; it muft follow, that pure vitriol does contain fea falt, or at leaft that fubftance which is the bafis of fea falt: and this will prove a lefs fingular obfervation, if it can be evinced, according to Becher, that all the known *falts* owe their origin to marine *falt*.

Mr. Lemery, in order to procure his aluminous *falt* from vitriol, does not pufh his diftillation too far, that the acid may remain engaged and entangled in that earth, by the union with which it is to form this *falt*, which is afterwards to be feparated by lixiviation; but Mr. Heliot pufhes the diftillation to the utmoft degree with a violent fire of three or four days and nights, fuch as Kunkel prefcribes, for the diverting vitriol of all its acid, that the remainder in the retort may contain little or no *falt* at all. He took eighteen pounds of Englifh vitriol, which he calcined to a rednefs, and by that means reduced it to fix pounds. This quantity, though put in a covered earthen veffel, acquired nine ounces in weight from the humidity of the air in two days; and in this ftate it was put into a german retort, and urged to that degree by the violence of fire, for fo long a continuance, that the remaining black mafs, though treated with all the care imaginable, and wafhed by repeated lixiviation, yielded only two ounces and a half of *falt*, and that of a very earthy kind. About nine ounces of phlegm had been feparated at the beginning of the diftillation, but when the white vapours began to appear, the veffels were all clofed, and fo kept to the end of the operation; the produce of which was an icy oil of vitriol, which was found in a black cryftalline form.

The fuccefs of the operation, as to the procuring this icy oil of vitriol, depends on the nice luting the junctures of the veffels, fo as to prevent all communication with the external air; for otherwife the vapours attract a moifture from the air, which renders them fluid in the receiver. The receiver muft alfo be placed at a confiderable diftance from the retort, that it may be cool enough to condenfe the vapours, and large enough to prevent their exploding, for want of room; for though the preceding calcination has carried off the more volatile parts, yet there remains matter enough for great explofion, and for the formation of a fubftance not lefs inflammable, than crude fulphur, were the acid in a lefs proportion.

The beft method is to fit to the neck of the retort a receiver with two necks; the one of which receives that of the retort, and the other is received into a capacious fingle receiver of the common kind.

The icy oil is not eafily got out of the receiver, for it exhales fo ftrong a fulphureous vapour, that if it be placed lower than the operator's head, it would fuffocate him in a moment.

This icy oil is black, becaufe it carries over with it a quantity of that oily matter, which no vitriol is ever entirely free from, and which is always found in the mother water, as it is called, of vitriol, after the repeated cryftallifations of the *falt* from it; and it is well known, that any inflammable fubftance, in ever fo fmall a quantity, will turn the pureft oil of vitriol black; nor is this all, for the acid fpirits alfo, when urged by a violent fire, carry over with them iron, or at leaft fuch particles, as are capable of becoming iron. This is eafily demonftrated in either the common or the blackifh cryftals of the icy oil of vitriol; for if thefe be diffolved in a large quantity of pure diftilled water, and allowed to ftand feven or eight days, there always precipitates to the bottom of the veffel a fediment, which, after it has been calcined, has many particles, which readily anfwer to the magnet.

Befides this oily matter, and thefe particles of iron, the oil of vitriol carries with it alfo a white, heavy, and cryftalline fubftance, of the nature of earth, which may be feparated, by means of fpirit of wine, from oil of vitriol, ever fo well rectified. The fame fort of earth is alfo found in the *falt*, which is extracted from the *caput mortuum*, left after the diftillation of the icy oil. The lixivium made by this author from the remaining mafs, left after the diftillation of the icy oil of vitriol, was expofed to the air, in a glafs cucurbit, for the fpace of fix months; and the faline liquor, concentrated by evaporation in a fand-heat, became green, and would by no means cryftallize. The firft faline pellicles had a faline, but earthy tafte: thefe precipitated by degrees of themfelves, and were finally fucceeded by others, which tafted acid, but not greatly fo. This liquor being evaporated to a drynefs, an ounce of the remainder was put into a retort, and four ounces of oil of vitriol was put on it, with one ounce of water, to forward the diffolution; this was kept in digeftion twenty days, at the end of which time the liquor acquired a green colour, which fhewed that there were yet in the mafs metallic parts for it to diffolve: this was finally diftilled with a gentle heat, to feparate the phlegm, and afterwards the fire was encreafed, to drive over the acid; the oil of vitriol came over as ftrong, as it was when put on, but much more fulphureous. The diftilled oil being returned upon the *falt*, with the frefh addition of a fmall quantity of water, became fo hot, that the veffel could not be held in the hand; which had not been the cafe in the firft mixture, at leaft not in any fenfible degree. Several more cohobations made it yet more and more acid, and at length it became fo cauftic, as to leave an efcbar on being juft touched upon the tongue.

The green colour, which the acid firft received, became at length changed into a blue one, which gave fufpicion that there was copper, as well as iron in the vitriol. This might appear ftrange, as it was Englifh vitriol that was ufed; but Kunkel has proved by experiments, that there is fome copper in all vitriol, even in the Englifh; nay he advances, that in the vitriol of iron, made with oil of vitriol and filings of that metal, there may always be difcovered fome fmall portion of copper; and, in fine, that there is no iron but contains fome portion of copper, and no copper but contains fome portion of iron.

After the fixth cohobation of this blue liquor, there remained a granulated and filamentous faline fediment, on the furface of which there was a fmall quantity of a yellow fublimation, refembling flower of fulphur; warm water being poured upon this matter, became of a greenifh colour; and this being digefted in a fand-heat, became afterwards reddifh,

reddifh, and precipitated to the bottom a white and very heavy powder; which, on a feries of examinations, proved to be of the nature of that opake white ftone, ufually found among the ores of metals, and called by the Germans *quartz.* The faline liquor, from which this was feparated, became yet redder by long digeftion, but when cold, it turned to a fine green.

This liquor being concentrated, by evaporation, to the quantity of two or three ounces, was put into a glafs veffel, with its pellicle, which foon precipitated itfelf to the bottom, in form of a thin cruft, covering the furface of the glafs in the manner of a wet paper. In five or fix weeks time, there became formed in this veffel, both at the bottom and fides, a number of large cryftals, of a beautiful green colour, and as the liquor dried away, thefe mouldered into a brownifh red powder.

In fine, there appeared, in the remainder of this liquor, another fort of cryftals; thefe were white and tranfparent, and were formed in fquare columns, with their extremities cut in the manner of thofe of the pyramids of the columns of *Glauber's falt*; they had alfo a bitter tafte, and left a remarkable fenfe of coldnefs on the tongue. Thefe appeared indifputably, by thefe and all other trials, to be true *Glauber's falt*. Mem. de l'Acad. Scien. Par. 1738.

Glauber's *fal mirabile* was long thought to be the produce of art only; but of late years, a natural *falt*, perfectly fimilar to Glauber's, has been found in many places. We have a full account, by Mr. Boulduc, of a fubftance of this kind, which had been found near Grenoble in Dauphine. The fame gentleman alfo found a *fal mirabile* in the waters of Paffy. The true Epfom *falt*, defcribed by Dr. Grew in 1696, is alfo either the fame as Glauber's, or at leaft Glauber's is the principal part of it. Stahl afterwards found a true *Glauber's falt* in the acidulæ, or ferrugineous waters, and did not fcruple placing this among the natural mineral *falts*. Hoffman alfo found a fpring of very bitter and purgative mineral water, a pound of which contained two drachms of this *falt*. The cathartic *falt*, found near Madrid, is alfo of the fame nature. See Hift. de l'Acad. Par. 1727. p. 29, 30. and the Memoires of the fame year, p. 375, feq. 4to.

It is to be obferved, that though Glauber made his *falt* known about the middle of the preceding century, yet Kunckel, in his Laborat. Chymic. affures us, it was known in the electoral houfe of Saxony an hundred years before. However this be, we owe the knowledge of it to Glauber, who called it *admirable*; and it foon acquired, and has ever fince maintained, the reputation of an excellent internal medicine in many cafes.

Glauber's falt may be obtained from borax, by mixing oil of vitriol with it. Mix four ounces of borax with one ounce and one drachm of oil of vitriol; upon fublimation, this gives the *fal fedativum* of Homberg, and the refiduum, expofed to a ftrong fire, affords *Glauber's falt*. This operation may be fhortened very much, for inftead of fublimation, the *falt* may be obtained by cryftallization, in light foliated laminæ. This *falt*, whether prepared by fublimation, or by cryftallization, has the property of diffolving in fpirit of wine; and if this fpirit of wine be fet on fire, the flame is green. Spirit of wine has no effect on borax, and the oil of vitriol digefted with it, does not make its flame green. Therefore it is neceffary, in order to give this greennefs to the flame, that borax fhould be united to an acid. Philof. Tranf. N° 436. p. 39.

SAL *nitrium*. See NITRIUM *fal.*

SAL *polychreft of Seignette*, a foluble tartar made with *fal kali*, inftead of *falt* of tartar. Mr. Boulduc defcribes this *falt* in the Mem. Acad. Scienc. 1731. See POLYCHREST, *Cycl.*

SAL *fedativum of Homberg*, This ufed to be made by diffolving borax in water, into which oil of vitriol was poured, and then diftilling this mixture, quieting *falt* was obtained. Mr. Geoffroy has lately taught us an eafier way of preparing it: he evaporates the liquor to the proper confiftence, and then allows it to cryftallize. Mem. de l'Acad. Par. 1732. See SEDATIVUM *fal.*

SALACSAE, in natural hiftory, a name given by the inhabitants of the Philippine iflands to a kind of bird, by whofe flight they pretend to divine the event of things. All the account we have of the bird is, that it is of a fmall fize, and is varioufly coloured, and has a long and large beak.

SALAMANDRA, the *falamander*, in zoology, a name given by authors to feveral fpecies of the lizard kind, but the principal are two, the *falamandra aquatica*, and *falamandra terreftris*.

The *falamandra aquatica*, or water *falamander*, is our common water newt, or eft, which is very common in fifhponds, and other ftanding waters, and is diftinguifhed from the reft by the flatnefs of its tail.

The manner of propagation in thefe animals is very fingular, and ferves to illuftrate the analogy between animal and vegetable nature.

The *falamandra terreftris*, or land *falamander*, is a fpecies of lizard very like the green kind, except that its head, and its belly, are thicker. Its tail is fhort, and its colour a fine black, marked with red fpots, and of a bright, fhining, and gloffy appearance. It is very common in many mountainous places.

The difference between this and the water kind is not only in colour, but in the fhape alfo of the tail; which in this is round, not flat as in that; yet there are fome who affirm, there is no fpecific difference between the two, but that the water kind, when it deferts that element, and comes to live on fhoar, alters in colour, and becomes round at the tail.

The opinion of this creature's being able to remain unhurt in the fire for a long fpace of time, is wholly falfe and fabulous.

The *falamander* is evidently a viviparous animal, yet it is fuppofed that the young are hatched from perfect eggs, while in the body of the parent animal. *Ray's* Synop. Quad. p. 274.

SALAMANDRINO, in ichthyology, a name given by the Italians to that fpecies of falmon, which Salvian calls *falmarinus*. It is diftinguifhed from all the other fpecies of this fifh, by its having a yellowifh back, with yellow fpots, and a forked tail. The flefh of this fpecies is very delicate. It loves cold and clear rivers. *Willughby's* Hift. Pifc. p. 199.

SALAMGA, in natural hiftory, the name given by the people of the Philippine iflands to a fpecies of fea fwallow. This is the bird, whofe nefts are fo famous as an ingredient in foops.

SALANDRA. See the article CHELANDIUM.

SALANDRIA. See the article CHELANDIUM.

SALAR, in ichthyology, a name given by fome authors to the trout. See TRUTTA.

Others apply the name to a young falmon while very fmall. See SALMO.

SALAYASIR, in natural hiftory, the name by which the people of the Philippine iflands call that fmall fpecies of duck, which is fo common thereabouts. This is an inhabitant of their lakes and marfhes, and is a perfect duck, and very beautifully coloured, but does not exceed the bignefs of a man's fift.

SALEFUR, a name given by fome of the chemifts to garden faffron. See SAFFRON.

SALEP, in the materia medica, the root of a fpecies of *orchis*. See the article ORCHIS.

Salep fhould be chofen clean, firm, and hard; it is very little liable either to decay, or fophiftication.

The people of the Eaft are extremely fond of *falep*; they look upon it as one of the greateft reftoratives, and provocatives to venery in the whole vegetable world.

That *falep* is the root of an *orchis*, no way differing from our common *orchis's* in virtue, but owing its appearance to the manner of preparing it, and confequently, that *falep* may be prepared from the roots of *orchis* of our own growth, Mr. Geoffroy has proved in the following manner. He confidered, that the method of curing one root in the eaftern parts of the world was probably the fame with that ufed in all; and obferving that Kæmpfer had defcribed the manner in which the Chinefe prepare their ginfeng, to make it pellucid, which was by firft fteeping, or macerating it in water, and afterwards carefully drying it; he determined to attempt the curing the roots of the common *orchis*, in a method not unlike that ufed to the ginfeng, in order to make *falep* of it. The *falep*, which we receive from Turkey, is a root of a white or reddifh colour, according to its different age; and as we receive it, is always tranfparent. As to our own *orchis*, if we attempt to dry the roots in the common way, they never will appear at all like the *falep*, but will become fhrivelled up and brown, and will always retain, or be ready to imbibe from a humid air, a great quantity of moifture. To prepare thefe, in imitation of the *falep*, Mr. Geoffroy chofe the largeft, plumpeft, and faireft roots he could find; thefe he nicely fkinned, taking off the whole outer rind, then throwing them into cold water, he fuffered them to macerate there fome time; after this he lightly boiled them; and after this taking them out of the water, and draining them, he had them ftrung upon threads, to be dried in a warm and dry air. When the roots were thoroughly dried, they were very tranfparent, and refembled pieces of gum tragacanth, and continued dry and hard. The roots thus prepared, may be kept ever fo long in a dry place, and will never attract humidity, or become mouldy and rotten; as they will always do in wet weather, if dried in the common way with their fkins on.

The *orchis* roots thus prepared may be reduced to powder, this powder will diffolve away in boiling water, and a fcruple of it will make a bafon full of jelly, in the manner of the Turkifh *falep*. This jelly is an admirable medicine in all the cafes, in which *falep* is prefcribed, and may be rendered agreeable by the addition of wine, fugar, fpice, &c. and the powder may be given with great fuccefs in affes milk, for difeafes of the breaft.

If the water, in which the roots have been boiled, be evaporated over a gentle fire in an earthen veffel, there will remain an extract of a vifcous texture, and a very agreeable fmell, refembling that of a meadow of flowers when the wind blows over it. Mem. de l'Acad. Scienc. Par. 1740.

SALIÆ, in antiquity, Roman virgins, dreſſed after the manner of the ſalii, who aſſiſted the pontif in ſacrificing. *Pitiſc.* in voc. See the article SALII, *Cycl.*

SALIAN *dance*, in antiquity. See DANCE and SALII, *Cycl.*

SALICARIA, *willow herb*, in botany, the name of a genus of plants, the characters of which are theſe. The flower is of the roſaceous kind, conſiſting of ſeveral petals, diſpoſed in a circular form, and growing out of the ſegments of a tubular cup; from the bottom of this cup there ariſes alſo a petal, which finally becomes an oval bicapſular fruit, containing a number of ſmall ſeeds, affixed to a placenta, and uſually ſurrounded and covered by the cup.

The ſpecies of *ſalicaria*, enumerated by Mr. Tournefort, are theſe. 1. The common long leaved *ſalicaria* with purple flowers. 2. The trifoliate purple flowered *ſalicaria* with hexangular ſtalks. 3. The roundiſh leaved purple flowered *ſalicaria*. 4. The narrow leaved Portugal *ſalicaria*. 5. The broad hyſſop leaved *ſalicaria*. 6. The narrower hyſſop leaved *ſalicaria*. 7. The white flowered hyſſop leaved *ſalicaria*. 8. The Spaniſh hyſſop leaved *ſalicaria* with long deep blue flowers. 9. The ſmalleſt narrow leaved *ſalicaria*. 10. The ſmalleſt Portugal *ſalicaria* with leaves like moneywort. *Tourn.* Inſt. p. 253.

SALICARIA, in zoology, a name by which Geſner, and ſome others, have called a ſmall bird, very much reſembling the muſcicapa, or fly-catcher, if not the ſame ſpecies.

It lives among the willows in wet places, and feeds on ſpiders, flies, and other inſects. *Geſner.* de Avib. See the article MUSCICAPA.

SALICASTRUM, a name by which Pliny, and ſome other botanical authors, have called the *ſolanum lignoſum*, the woody nightſhade, or bitter ſweet. *Ger.* Emac. Ind. 2.

SALICHA, in the materia medica, a name given by ſome of the old writers to cinnamon. Aviſenna and Serapion uſe it for the bark we call *caſſia lignea*, and the Greeks *hylocaſia*, when ſtripped clean from the wood.

The antients had two ways of collecting the barks of trees and plants for medicinal uſes; the one was the ſtripping them from the branches of trees, as we do at this time; the other was the cutting off the branches, bark and all, and drying them together. The *ſalicha* ſignifies, however, the *caſſia*, or cinnamon, thus ſtripped from the wood, not cut with it. The word *ſelach*, in the Arabic, from which it is derived, ſignifying *exuviæ*, or the caſting off the outer part of any thing. The *ſelach alhaie* is the *exuviæ ſerpentis*, or caſt ſkin of a ſerpent, and ſo of the reſt. The determinate ſenſe of the word *ſalicha* is, therefore, the bark of *caſſia* ſtripped from its wood, and is what the antients called *caſſia fiſtula*, from its being rolled up in the form of a pipe. But we have perverted their meaning in this term, and applied it to the fruit of the pudding pipe tree, that being our *caſſia fiſtula*. Damocrates, in his iambics, and alſo in his antidote, mentions this bark under the name of *caſſia fiſtula*; and Scribonius Largus, among the reſt, expreſsly informs us, that it was the bark, not the fruit of a tree, that was at his time known by this name. Aviſenna, and the more correct writers, keep this word for the name of *caſſia*, never expreſſing cinnamon by it, though others do. They call cinnamon *darſini*.

SALICINEA, in the materia medica, a name uſed by Geſner, and ſome other authors, for the *nardus Celtica*, or Celtic ſpikenard. *Ger.* Emac. Ind. 2.

SALINE, a name given to a preparation of ſea *ſalt*, procured from the froth of the ſea, hardened by the ſun in hot countries. It is called by ſome authors *pilatro de Levante*, and is uſed in glaſs-making; and in the making the fine purple colour from cochineal, by boiling it in a ſmall quantity, with the bran and fœnugreek, of which the magiſtery is made for that purpoſe. *Neri*'s Art of Glaſs, p. 173.

SALINE is alſo the name given by authors to ſprings of *ſalt* water, called by us *ſalt wells*, *ſalt ſprings*, and *brine pits*. Moſt parts of the world are found to have theſe, but thoſe of Franche Compté, in France, ſeem to be the moſt remarkable. The ſprings are ſituated in deep caves, and theſe in the greater work are about four hundred feet in length, and fifty feet in breadth: into this work they deſcend by a ſtone ſtaircaſe of forty ſteps, and thence by a wooden one of twenty; at the bottom of theſe ſtairs is a cave with an arched roof. This firſt cave, or vault, is forty feet long, and thirty two feet and a half broad, and in it are ſix ſprings of *ſalt* water, and two ſprings of freſh water; all which iſſue out of the ſame rock, in the ſpace of fourteen feet in length. From this cave they go into others, which are ſupported in the middle, each by a row of thick pillars, from which are carried double rows of arches. They then paſs through two gates into a ſpacious vault, thirty five feet high, and ſupported, nigh the entrance, by four ſtrong pillars, placed in form of a ſquare. In the middle ſpace, between theſe pillars, is a baſon of a very conſiderable ſize, into which the *ſalt* water from ſeveral ſprings is collected: and in the ſame vault, beyond theſe pillars, are four others placed in a row, ſupporting different arches, of ſixty feet in length, and forty eight feet in breadth; beyond which there is an irregular ſpace, ſixty three feet long, in which are ſix or ſeven ſprings of *ſalt* water, and ten or twelve of freſh. The *ſalt* waters of theſe ſprings, and of the ſix ſprings before-mentioned, are kept ſeparate from the freſh water, and are all conveyed through gutters to the baſon before-mentioned. From this baſon, they are drawn out by a wheel and buckets into four large ſtone baſons or reſervoirs, one of which holds fifteen thouſand hogſheads, and the other three together twenty-five thouſand hogſheads. From theſe reſervoirs they are to be drawn off, as occaſion requires, into ſmall ciſterns placed near the boiling houſes; and the waters contained in the ſeveral baſons, as they are drawn from the ſprings, at different times, and are of different ſtrength, are mixed together before the boiling, in ſuch proportion, that each pound of the water yields about three ounces of *ſalt*.

The water of the freſh ſprings is alſo collected in the caves into a freſh water baſon prepared to receive it, and is raiſed by means of a crane to the level of a little brook, through which it runs away by a ſubterranean conduit. *Brownrig* of Salt, p. 94.

SALINE *principle*, a term uſed by the chemical writers, to expreſs a conſtituent part of ſeveral mixt bodies, on which their exiſtence in that form depends; and which, though always exiſtent in them, and always ſeparable by art, is yet not perceivable in many of them in the complex.

The *ſaline principle* of vitriol is of the number of thoſe made by ſome a neceſſary principle of the exiſtence of that body, and by others ſuppoſed not to exiſt at all, otherwiſe than in the general form of that compound *ſalt*. But the exiſtence of it, in a ſeparate ſtate, is proved by this experiment: take four or five gallons of the ſtrong vitriolate water at the water works, as it runs from the beds of pyrites to the great ciſtern; this is to be choſen, becauſe having yet undergone no operation but that of the air and water, it muſt needs be in the moſt ſimple and natural ſtate; diſtil from this about two thirds of the inſipid water, let the glaſſes cool, and the water will then let fall a vitriol of a lovely pale green colour, together with a large quantity of ochre or yellow earth. Evaporate away a third part of the remaining liquor, and more vitriol ſtill will be produced of a paler colour than the former, and ſome yellow earth will alſo be thrown down, though leſs in quantity than before; after this has been repeated five times, inſtead of vitriol, a yellow *ſalt* will be obtained; and after that, on more evaporations, a white *ſalt* will be every time obtained, which will be extremely different from vitriol both in colour and taſte, being fiery and pungent, and partaking ſcarce at all of that acrid and nauſeous aſtringent taſte, which is ſo peculiar to vitriol. It is unctuous like *ſalt* of tartar, and cleanſing like ſoap, rendering the hands waſhed with it ſoft and ſupple; whereas the common vitriol makes them very harſh and rough; finally, this laſt *ſalt* diſſolved in water appears fatty and mucilaginous.

From five pounds and a half of the laſt lixivium four pounds of this ſalt will be obtained, and half a pound of the liquamen will never congeal. It is remarkable, that this *ſaline* matter is the moſt ſoluble of all the ſorts, as the greateſt quantity of it may be kept fluid in the ſmalleſt quantity of water we know of in any experiment of this nature.

The liquamen remains thin, and is of an acrid and fiery taſte, ſcarce ſupportable on the tongue. See the article LIQUAMEN *pyriticum*.

The white ſalt, which is called the *ſaline principle* of vitriol, being put into a retort, and diſtilled in a ſand furnace; the far greater part of it comes over in form of a highly acid ſpirit, eſpecially that coming laſt in ſmall drops. This liquor being rectified in a tall glaſs body, a volatile ſulphureous liquor ariſes immediately on the application of the heat. The ſmell of this is ſo ſubtile, and penetrating, that it is almoſt inſupportable, and yet it is clear as water and inſipid to the taſte. This may be preſerved in its full perfection many years, only by keeping it cloſe ſtopped, not letting fall any ſediment. The remaining liquor is the common acid liquor of vitriol, and by diſtillation may be ſeparated into ſpirit of vitriol, and that heavy and corroſive liquor, commonly called oil of vitriol.

In alum, vitriol, and mineral ſulphur, the *ſaline principle*, which in each of them is by far the chief part, both in quantity and energy, has much the ſame nature and properties. In the laſt indeed it is clogged with ſulphur; for the true nature of common ſulphur is, that it is a vitriolic ſalt, the very ſame with that of common vitriol; and the ſulphureous parts, which give it that form and exiſtence which we expreſs by the word ſulphur, are leſs copious than could be imagined, compared with the *ſaline*, which are genuine vitriol, differing in nothing from the common vitriol, but that it contains a ſmaller admixture of terreſtrial and metalline parts. Phil. Tranſ. N° 103.

SALINE *earths*. The chemiſts under this, as a general head, reckon all thoſe *ſaline* and *earthy* ſubſtances, which are calcined or burnt in the fire; as all the kinds of lime, potaſhes, ſoot, and the like; theſe being ſo many mixtures of ſalt and *earth*; and all ſalts appearing to them, indeed, on a rigorous examination, to be only *earths* of different natures, which when reduced to a certain degree of ſubtility or fineneſs of parts, ſo as permanently to diſſolve in water, are then emphatically denominated ſalts. *Shaw*'s Lectures, p. 67.

SALIVAL (*Cycl.*)—SALIVAL *ducts*. Dr. Trew endeavours to shew, that the vessels called *salival ducts*, by Coschwitzius, are not truly *salival ducts*, but veins. Phil. Transf. N° 457. Sect. 7. p. 441.

SALIVARIS, in botany, a name given by some authors to the pellitory of Spain, or pyrethrum of the shops, from its quality of draining a large quantity of the saliva into the mouth by its great heat and acrimony. *Ger.* Emac. Ind. 2.

SALIX, the *willow*, in botany, the name of a genus of trees, the characters of which are these. The flower is of the amentaceous kind, being composed of a great number of stamina arranged in form of a spike: These are the male flowers, and are barren; the embryo fruits appear on other trees of the same species, which produce no male flowers. These are disposed like the stamina into the form of a spike, and finally become conic capsules, which when ripe open into two parts, and discharge a seed winged with down.

The species of *willow* enumerated by Mr. Tournefort are these. 1. The common white tree *willow*. 2. The common black *willow* with leaves not serrated. 3. The common red *willow*. 4. The yellow *willow* with crenated leaves. 5. The almond *willow* with auriculated leaves, green on both sides. 6. The *willow* with almond like leaves auriculated on each side, which casts its bark. 7. The *willow* with long and very narrow leaves white on both sides. 8. The long narrow leaved *willow*. 9. The long hoary and pointed leaved *willow*. 10. The brittle or crack *willow*. 11. The dwarf *willow* with scaly heads. 12. The great bay leaved mountain *willow*. 13. The round silvery leaved *willow*. 14. The dwarf broad leaved erect *willow*. 15. The broad leaved creeping *willow*. 16. The round leaved creeping dwarf alpine *willow* with leaves greyish underneath. 17. The round leaved dwarf *willow*. 18. The creeping round or alder leaved alpine *willow*. 19. The mountain creeping *willow* with leaves woolly on each side. 20. The dwarf *willow* with leaves smooth on both sides. 21. The dwarf hoary flax leaved *willow*. 22. The dwarf *willow* with short narrow and woolly leaves. 23. The Pyrenean mountain *willow*. 24. The smooth narrow leaved creeping *willow*. 25. The Alpine *willow* with shining leaves like serpyllum. 26. The sallow or *willow* with broad roundish leaves. 27. The sallow with pointed roundish leaves. 28. The broad leaved white *willow*. 29. The Portugal *willow* with auriculated sage like leaves. *Tourn.* Inst. p. 591. See Tab. 1. of Botany, Class 19.

SALIX *amerina*, in botany, is used for *agnus castus*. *Lemeri* Tr. des drog. p. 18. See AGNUS *castus*.

SALLIUS *lapis*, a name by which Ludovicus Dulcis, and some other writers of his time, have miscalled the *lapis samius* of the antients. That author describes it as being heavy, white, and brittle, and gives it the same virtues with the *lapis samius* of Pliny.

SALLY (*Cycl.*)—SALLY-*port*, in a fire ship, is a great opening in her side, made on purpose for the men to escape by, when they have grappled an enemy, and fired their train.

SALMO, the *salmon*, a well known fish. It is distinguished from other fish of the truttaceous kind by these characters. It is of an oblong body covered with very small scales, a small head, a sharp nose, and a forked tail. Its back is bluish; the rest of its body whitish, or reddish, and usually spotted. Its under jaw is bent upwards, and that sometimes so much as to make itself a sinus in the upper, by constant motion, and sometimes to perforate it. The *salmon* is first produced from its parent's spawn in fresh rivers, thence it goes into the sea to acquire its growth and feed. And at the time of its full growth, and in the season for spawning it removes into the fresh waters again.

The *salmon* in the different stages of its life and growth has different names. The Latins called it when young *salar*, when of a middle growth *sario* or *fario*, and only when full grown *salmo*. In England the fishermen have names for it in every year of its growth. In the first it is called a *smelt*, in the second a *sprod*, in the third a *mort*, in the fourth a *fork-tail*, and in the fifth a *half fish*; finally, in the sixth it is called a *salmon*. This is the common agreement of our fishermen, though there are some who say the *salmon* comes much sooner to its full growth. *Willughby*'s Hist. Pisc. p. 139.

In the Artedian system of ichthyology, the characters of this genus of fishes are these: the branchiostege membrane on each side contains eleven, twelve, or nineteen bones. The body of the fish is generally variegated with spots. The back fins are placed nearer the head than those of the belly, and the teeth are large, and are placed in the jaws, and palate, and on the tongue.

The species of this genus enumerated by Artedi are these. 1. The *salmon* with the snout often reaching beyond the lower jaw. This is the common *salmon*. The spots are black, and the back convex, the belly flat and plain. 2. The *salmon* with grey spots, and with the end of the tail equal. This is that sort of *salmon* which we call the grey; its body is broader and thicker than the common *salmon* in proportion to its length. 3. The broad *salmon* with black and red spots, and with an even tail. This is the kind we call the *scurff*, or the *bull trout*. 4. The forked tailed *salmon* with only black spots, and with a longitudinal furrow on the belly. This is the *trutta lacustris* of authors. Its flesh is red. Its weight about twenty pound, when full grown; it will sometimes weigh much more. The upper jaw in the spawning time is crooked, the head and back are of a bluish green colour. 5. The *salmon* with the lower jaws somewhat longer than the upper, and with red spots. This is the common river trout. The tail of this fish is scarce at all divided; the pinna ani has ten rays; the spots below the lineæ laterales are red, those on the head and back are blackish. 6. The oblong *salmon* with two rows of teeth in the palate, and with only black spots. This is that sort of trout, called by the Germans *huch*; the sides and the fins are red, and the body is slenderer than in the common river trout. There are some spots on the lower jaw, but none on any other part of the head. 7. The twelve inch *salmon* with five rows of teeth in the palate. This is the fish called by authors the *carpio lacus benaci*, and by us the *gilt charre*. The body is much broader than that of the common trout. The flesh when boiled becomes red. It has eight spots on each side in the lower jaw, and black spots in the back. The sides and belly are silver coloured, and the snout is bluish. 8. The twelve inch *salmon* with red belly fins, and the lower jaw somewhat the longer. This is the *salmo lapponicus* of Linnæus. The *torgoch* of the Welch, and probably the *red charre* of some parts of England. The body is more slender than that of the river trout. The belly is generally reddish. The flesh of this species scarce becomes at all red in boiling; the spots are broad, but of a faint and obscure colour. 9. The forked tail *salmon* with the lineæ laterales turning upwards, this is the umbla of authors; it has three or four foramina under the eyes, and has no middle line of teeth in the palate. The belly and the sides below the lineæ laterales are yellow. The head is bluish, and there are some whitish spots above the lateral lines. 10. The twelve inch *salmon* with the upper jaw longer than the under. This is the fish called the *pavelin* by the Germans, and the *umbla altera* of authors: it has yellow spots on the sides, and the belly and its fins are also yellowish. The lateral line is strait. The middle row of teeth in the palate is scarce perceivable; but there is a double row of them in the upper jaw, with a skin resembling a lip between them. The flesh boils red. *Artedi*'s Gen. Pisc. p. 9.

The *salmon* is a very peculiar kind of fish. It is bred in rivers, but goes every year from thence into the sea; and at a certain season of the same year it always returns up into the fresh water again; and what is remarkable, is, that so far as observation has been able to trace them at any time, the same shoals of *salmon* always return into the same river out of which they swam, not into any other; so that the people who live on the *salmon* fishery are not afraid for their rivers being cleared, by all the fish in them going down into the sea, for they know that they will all return up to them again at a proper time. When the *salmon* has once entered a fresh river, he always swims up against the stream, and often will go an hundred leagues up a river in the large and long rivers; and the people at this vast distance from the mouth have the pleasure of taking a fish, that is properly in part of the sea kind. It is also remarkable, that the rivers which most abound with *salmon* do not make the seas about their mouths any more abound with them than others, particularly the harbour of Brest affords no *salmon*; though the river Chateaulin, which discharges itself into it, is the richest *salmon* river in France.

Another singularity, in regard to the *salmon*, is their swimming up the rivers together in such vast numbers. It is to be allowed, indeed, that herrings, mackrel, and many other fish, do in the same manner appear on the coasts at certain seasons in prodigious numbers; but the reasons for their coming together in these quantities, are much more easily explained than that of the *salmons* doing so. The herrings, when they come in such prodigious shoals to the coasts of Normandy, have been found to be allured thither in these numbers by a prodigious quantity of a particular sort of sea worms which are their favourite food, and which are found to cover the whole surface of the sea at that time. Rondeletius has described these insects under the names of sea caterpillars; they always appear in the months of June, July, and August, which are the herring seasons at that part of the world; and probably the same cause will be found to bring them to other places, if sufficiently enquired into, as these and some other fish come to certain places in shoals to get food. The *salmons* do it in order to propagate their species. The spawn of the *salmon* is never deposited but in rivers, and at the time that these fish are found up the rivers, it is only with this intent; the females go first, and the males follow as far as the others please to lead them, which is usually to some convenient place in shallow water, where the spawn when deposited is not buried under too great a quantity of water, but has the advantage of a continual warmth from the sun's heat.

Salmon do not equally frequent all rivers, though they may seem to us equally proper for their reception. There are

two rivers which open themselves into the harbour of Brest very near one another; the one of these is famous for the quantity of *salmon* in it, and the great advantage of the fishery, the other never has any of these fish in it. It most probably is owing to their finding plenty of food, and proper places for the depositing their spawn in the one of these rivers, and not in the other, that makes this regular choice. *Des Landes* Trait. Phys.

SALMON *pipe*, in our old writers, an engine to catch *salmon*, or such like fish. 25 H. 8. c. 7. *Blount*, *Cowel*.

SALMON *trout*, in zoology, the English name of the fish called *trutta lacustris*, by Gesner and other authors. It is caught in lakes, in mountainous countries, and grows to a very considerable size, sometimes to thirty, forty, or fifty pounds weight. It resembles the *trout* in figure, but its belly is very flat, and has, as it were, a long furrow or cavity running the length of the belly. Its back and head are of a very beautiful bluish green colour; and the whole fish, especially its back and the upper parts of its sides, are marked with numerous black spots. Its back fin is also spotted with black, and its scales are small and silver coloured. *Gesner* de Pisc. p. 1210.

SALMULUS, in zoology, the name of a small fish of the truttaceous kind, called in English a *samlet*.

It seldom grows to more than seven inches in length. It is very like the common trout, but differs in these particulars. 1. It is broader in proportion to its length. 2. It has fewer spots, and those of a deader colour. 3. It is white in its general colour. 4. The tail is more forked. 5. The lines on the sides are smaller and paler. 6. The sides under the lines are yellowish; and 7thly, It has several bluish streaks near the side lines. It is caught about Hereford, and in some other places. *Willughby*'s Hist. Pisc. p. 189.

SALPA, in zoology, the name of a fish caught in great plenty in the Mediterranean, and common in the markets of Italy and elsewhere. Its usual size is about a foot in length, and it has a somewhat flatted, yet considerably thick body, and a strait back. Its sides are variegated with a number of fine gold coloured lines running longitudinally; the intermediate spaces between these toward the back are of a bluish green, toward the belly they are white; there are usually eleven of these lines on each side. The mouth is extremely small, and each jaw has only one row of teeth, which are thick and broad below, and terminate in a double point. It has only one back fin, the anterior rays of which are prickly, the hinder ones soft. It generally keeps about the shores, and swims in large shoals. Though it be a very beautiful fish it is no very delicate tasted one, nor much regarded, the poorer sort of people usually buying it up. *Rondelet* de Pisc. l. 5. c. 23. p. 154. *Aldrovand* de Pisc. l. 2. c. 21. See Tab. of Fishes, N° 55.

SALPUGA, in natural history, a name given by some of the Latin writers to the *solipuga*, a small kind of spider, that buries itself in the sands in hot countries, and bites men who come in its way in a very venomous manner. It is common in Africa, and in some parts of Europe; Sardinia in particular, according to Solinus, abounds with it. See the article SOLIPUGA.

SALSIRORA, in botany, a name used by some authors for the *ros solis*, or sundew. *Ger.* Emac. Ind. 2.

SALT (*Cycl.*)—*Salts* are defined to be solid fossile bodies, friable, pellucid, not inflammable, but fusible by fire, and congealing again in the cold; soluble in water, so as to disappear in it, naturally concreting into regularly figured crystals, and impressing a sensation of acrimony on the tongue.

These are the characters and qualities common to all *salts*, and to no other bodies: and these they always manifest when pure and freed from heterogeneous substances; but in the state in which they are naturally found in the earth, though they have that in their taste alone which may sufficiently distinguish them, yet they do not exhibit all their genuine characters: some of them being found solid and pure, either within the earth or on its surface, but commonly without their proper form; others embodied in earths and stones, as the particles of metals in their ores; and others in a fluid state suspended in waters.

Of the fossils of this class, nature therefore affords us three distinct orders, and under those they are distinguishable into five genera. The *salts* of the first order are those found native and pure, either in the earth or without its surface, and exhibiting all other natural characters, though often without their proper form. Of the second, are those found not native, but in form of ores, never pure, but distinguishable by their taste, and immersed in and blended with the constituent matter of earths and stones in extremely small particles. And of the third are those naturally found suspended in waters, and in a fluid form, but ready to assume their proper figures on the evaporation of a part of that water.

Of the first of these orders are the common *alimentary salt* or *muria*, and the *natrum* or *nitre* of the antients. Of the second are *alum* and *nitrum*, and of the third are *borax*, and *halcryptium*, an alkaline *salt* hid in the chalybeate waters. *Hill*'s Hist. of Foss. p. 380. See the articles NATRUM, ALUM, NITRUM, BORAX, and HALCRYPTIUM.

The *muria* or *alimentary salt* is a body which appears to us under an almost infinite variety of forms, but is always immediately distinguished by applying it to the tongue, and always assumes the same figures after a regular crystallization. Sea water, and that of *salt* springs, sustain it in a liquid form; and beside this state, it is found in vast masses in the earth, either of a fine pellucid structure, called *sal gem*, or else variously debased and coloured, or in form of a striated body, resembling the fibrariæ, or fibrose talcs, as they are called. This is the true *sal ammoniac* of the antients. See SAL *ammoniac*. But in which ever of these forms this *salt* is found, it affords the same crystals on evaporation: these, according to the degree of heat used in the evaporation, are either pyramidal, cubic, or parallellopiped. All these *salts* are soluble in water, but they require different quantities of it to dissolve them, and this makes one of their criterions. This *salt* requires three times and one seventh its own quantity of water, to make a perfect solution. The sea water, in different parts of the world, is very differently sated with it, some parts containing twice as much as others. *Hill*'s Hist. of Foss. p. 380.

Alimentary salt, according to the various ways of preparing it, may be distinguished into several kinds. 1. *Bay salt*, prepared by evaporation by the heat of the sun. 2. *Marine salt* boiled, which is extracted from sea water by coction. 3. *Brine salt*, or fountain *salt*, prepared by boiling from natural brine, whether of ponds and fountains, or of lakes and rivers. 4. *White salt*, prepared from sea water, or any other kind of *salt* water, first heightened into a strong brine by the heat of the sun, and operation of the air. 5. *White salt*, prepared from a strong brine, or lixivium, drawn from earths, stones, or sands, strongly impregnated with common *salt*. 6. Refined *rock salt*, which is boiled from a solution of fossile *salt* in *salt* water, or in fresh. And 7. *Salt upon salt*, which is made from bay *salt* dissolved in sea water, or other water, and boiled to a white *salt*. *Brownrig*, on Salt, p. 50.

Bay SALT. This *salt* is of two kinds: the first drawn from sea water, as is practised in France, Spain, and Portugal, and many other hot countries; the other from the water of *salt* springs, or lakes, as in the Cape Verd islands, in the island of Tortuga, Turks island, and many other parts of America.

The first kind is, in times of peace, imported into Great-Britain in very large quantities, and our colonies and fisheries in America commonly supply themselves with the latter.

There are several methods practised, in the different parts of the world, of making this useful *salt*; of which some are more simple and easy, others more complex. It is sometimes prepared by a total exhalation of the water in which it was dissolved; but the most simple and easy method of making it, is, when the water of ponds and lakes, impregnated with *salt*, is totally exhaled by the force of the sun and air, and the *salt* is left concreted into a hard crust at the bottom of the lake. We have many instances of *salt* thus prepared, in the different parts of the world. In the Podolian deserts, near the Borysthenes, is a *salt* lake, whose water, by the heat of the sun, is exhaled, and all its *salt* left in form of ice, in so hard cakes, that it is to be cut away in large pieces with tools; and in Russia, on the borders of Crim Tartary, there are vast desert plains, which in summer produce neither tree nor plant, but are covered with *salt*. In the West-Indies we are told of a *salina* of this kind, called *garci mendoza*, forty leagues long, and sixteen broad. And in the kingdom of Algiers there are many *salines*, which in winter are so many *salt* water lakes, and dry plains in summer, covered with a crust of *salt*, which is dug out, and sold in very large quantities; and there are more of them in several parts of the world.

Large quantities of *salt* of this kind, however, are prepared by the art and labour of man. The English in the Cape Verd islands have long been used to prepare great quantities of it. The islands, which principally afford this *salt*, are chiefly Mayo, Bonavista, and Sall. The subjects of Great-Britain have long enjoyed a liberty of preparing *salt* in the two first of these, free of all taxes, except a late one imposed on the captains for every ass which they hire of the inhabitants, to carry the *salt* to their boats. *Brownrig* of Salt, p. 1 to 19.

The time of making this *salt* is in the dry season, which in those islands is usually from November to July: those ships, therefore, which are to load with *salt*, are to be there in the months of December or January. On the west side of Mayo, or May island, they find themselves, as soon as on shoar, upon a bank of dry loose sand, fifty or sixty yards broad; and when they have passed this, they enter upon the *salina*, or *salt* marsh. This is a plain of half a mile broad, and a mile long, the greater part of which is hollowed out into pits, which, at a proper season of the year, are filled to the depth of eight inches with strong brine, or pickle. See SALT-*marsh*, infra.

Some authors, who have given accounts of these works, say, that this brine is only sea water, let in through holes in the bank at spring tides. But this is an error, the brine of these pits being much more strongly impregnated with *salt*,

salt, than the sea water, and being the real produce of *salt* springs, with which the whole island abounds at a certain depth. In moderate seasons, the sailors find these pits ready filled with brines, but in times of great drought, they are obliged to dig little wells to come at the water, and with this they fill the pits to the proper depth. The bottom of these pits is a kind of close earth, which retains the water, and the sailors, who first arrive at the place, clean out as many of these as they have occasion for, and others, who follow them, do the like. After the pits are properly filled, the heat of the sun exhales the water very fresh, and leaves all the *salt*, which forming itself into crystals, sinks to the bottom from time to time. As this is done very quick in this season, they twice a week draw out all the *salt* that is ready formed with rakes, and lay it in little heaps to drain; after this they add it to their general cargo in one large heap, where it soon dries entirely, and becomes fit to be put on board their ships.

If the weather be favourable, a large ship may be, in this manner, loaded with *salt* in a fortnight, and it is often done much sooner, the sailors finding the pits, at their arrival, ready filled with concreted *salt*.

Though a ship be thus very easily loaded with *salt* in good seasons, yet bad weather, and delays upon the voyage, often are the occasion of ships returning without their loading; for the wet destroys all the *salt* they had prepared, and the tornados toss up the sand, and mix it with the *salt*, and at the same time make it impossible to load it. This trade might therefore be carried on with much greater advantage, if there was a British factory established at the place, whose business it should be to make *salt* in the dry season, and sell it afterwards to the sailors, and this might be done at a cheaper rate, than what the seamen can make it for, it usually standing them in about sixpence a bushel.

The *salt* is made at Bonavista in the same manner as in the island of May; but the brine is weaker, and the *salt* does not kern, as the sailors call it; that is, it does not granulate, or crystallize, so soon as in the other place; but the ships are often forced to be contented with this, when either the isle of May is too crouded, or when the rainy season sets in there, while they are at work; for though these islands are but eighteen leagues distant from one another, the rains are sometimes several weeks later in one than in the other. The weather is not excessively hot in either of these islands, the sailors finding it tempered continually by breezes from the sea. *Brownrig* of Salt, p. 26.

The British colonies in America have also, for near a century past, been used to supply themselves with *salt* of this kind from Tortuga, one of the Leeward islands, uninhabited, and situated near the coast of Caraccas, on the Spanish main, and the Turk's island, which lies not far from Hispaniola; and many vessels, freighted from North-America to Barbadoes, and others of the Caribbee islands, were accustomed to go from thence to these *salt* islands, and carry back a loading of *salt*, for which they always found a market in Newfoundland, New-England, and other places in North-America. The Spaniards, who had been used to suffer this without molestation, at length seized such ships as they found loaded with this *salt*, and the traders in this way were compelled to go in a sort of fleet from Barbadoes, and the neighbouring places, and they kept together till out of danger. The method of making the *bay salt* in these places, is much the same with that already described; only in the American isles they do not collect it out of small pits, but out of large ponds and lakes; and the sailors often find vast quantities of clean and good *salt* ready prepared, lying at the bottom of these lakes.

It has been reported, as a very extraordinary thing, that in these American islands the *salt* never kerns, or forms into grains, except during the hot season of the year; but this is a story much improved in the telling, and the whole truth seems to be this. During the constant rains, the ponds overflow, and great quantities of *salt* are washed away; and when these are over, the ponds and lakes remain full of a very weak brine, so that no *salt* can crystallize in them till most of the water is exhaled, and this does not happen, till toward the time of the rainy season's setting in again; but as this season begins only in showers once in two or three days, and those not great, the *salt* is easily prepared from the brine of the pits, which is then very rich, notwithstanding this slight interruption. These first showers of the rainy season are always a sort of tornados, and wash off a great quantity of *salt* from the surface of the earth into the ponds; and, in general, while they are so moderate, that there falls no more water in them, than is daily evaporated by the sun, they are an advantage in keeping the ponds supplied, which otherwise, after the continuance of heat that has been at that time, would be dry, and in no condition for working.

Bay salts, prepared in France and other parts of Europe, are of the same kind, in the general meaning of the processes, with those of the African and American islands. As the *salt* is there prepared from the water of *salt* springs, it is in Europe made from sea water. *Bay salt* is not extracted from sea water, in the colder parts of Europe, as on the coasts of Germany, Denmark, and Sweden, but in places situated in a more southern climate, as on the coasts of France, Spain, and Italy. Some marine *bay salt* has also, of late years, been made in England at Limington, and in some other parts of Hampshire, and in the Isle of Wight: but in these places it is only made in drier summers, and then rather by accident than design, it being collected from ponds, which were originally made for heightening of sea water, or reducing it into a strong brine by the heat of the sun, in order to lessen the expence of fuel, in boiling it into white *salts*. *Brownrig* of Salt, p. 35.

The ponds, in which this *salt* is made, nearly resemble a rude kind of *salt* marsh, described by Agricola, in which the sea water is received into a pool, and thence, by a trench, is conveyed into several pits dug in the earth; and when it has stood some time in these pits, it is suffered to run out into others, and so on, till the brine is strong enough to crystallize.

This is the case in our English *salt* works; but the French marshes, in which a vast quantity of *bay salt* is annually prepared, are made in a much more artful manner. A full account of which is given in the Philosophical Transactions, N° 51. See SALT-*marsh*, infra.

When rainy weather happens, in the time that the French are making this *salt*, they keep it out of the pits as much as possible; but unless it rain much, the damage is not very great, the heat of the sun sufficiently exhaling it. If it rain very violently for a whole day, all the care in the world cannot so well keep it out, as to render it practicable to make *salt* for the three or four next days. But when it has rained successively for five or six days, they are forced to empty all the water out of the beds, and take in fresh, before any *salt* can be made. This is an accident, however, that rarely happens to them. The hottest years always afford the most *salt*. In the very hot weather, there is *salt* made even in the night; and it is always observed, that there is more *salt* made in stormy weather than in calm. The west, and north-west winds, are always found to be most useful to the *salt* makers; and in good seasons, the French *salt* workers draw out the *salt* from their pits every other day, and draw more than an hundred weight from every pit. This they do with instruments that will retain the *salt*, and are pierced full of small holes, which let the water run off.

Those pits which are made in a reddish earth, are always found to make the *salt* more grey; and those in a bluish earth, more white; and it is always observed, that if more than the proper quantity of water be let in, the *salt* is the whiter, but there is the less of it in proportion. All the marshes should have a clayey viscid earth, neither spungy nor sandy. There is a great deal of caution to be used in drawing out the *salt*, that the earth, or other impurities of the pit, do not mix with it; for two workmen, who are differently skilled in their business, will procure from the same pit a very brown and foul, and a very clean and white *salt*; and they always separate a pure and white *salt*, which rises to the top of the water, before the other granulates, and falls to the bottom. This pure *salt* is not only of a better colour than the other, but is in smaller grains, and this is what the politer people use at their tables. These marshes are overflowed once a year, at the end of the season, about a foot high, and this preserves them from year to year. *Brownrig* of Salt, p. 44.

The French have so many works of this kind, that in favorable seasons as much *bay salt* is made in a fortnight, as serves for the whole year, not only for the home consumption, but for that of other nations, who purchase it of them, and who use much more of it than the French themselves. But, on the contrary, when a rainy season comes, there is often a scarcity for a whole year afterwards. It is wonderful, that though the method in which the French work has been long known among us, we have never attempted it ourselves, either here, or in our American colonies, which would seem a very easy matter, the principal care being in the first erecting the works, or *salt* marshes. See SALT *marsh*, infra.

The several kinds of *bay salt*, made in the different parts of the world, are found to differ greatly from one another in several particulars; as 1. in the size of the crystals, which is owing to the heat of the sun, and the time it lies in the pits. The French cream of *salt*, and the blown *salt* of the isle of May, are fine and small grained. The Portugal *salt* is larger grained than that of France; and that of Tortuga is larger than either. 2. In purity. As all *bay salt* has some mud, slime, or the like, in the making, and some kinds are mixed with the bittern *salt*, or what is called Epsom *salt*, they are all more white while dry, and more pellucid when moist, and they differ in colour, according to the earth which makes the bottoms of the pits. Thus some of the French *bay salt* is grey, some reddish, and some white, according as a blue clay has lined the pits, or a red, or white one. 4. Some kinds of *bay salt* are more apt to contract a moisture from the air than others: this is sometimes owing to

to the smallness of the grain, and sometimes to a mixture of a calcarious, or alkaline *salt* with it. And 5. some kinds have an agreeable smell in large heaps; such are the Portugal, and the Hampshire *bay salts*; and this seems owing to the sea water, they were made from, having a bituminous matter in it. 6. It differs greatly in taste, according to the various foreign mixtures it contains; and it will often alter in taste, and other qualities, by long keeping. Thus the *salt* of Peccais is so bitter, when new made, as not to be eatable, but after keeping a while, it becomes very pleasant. This is owing to its containing at first a large portion of the bittern *salt*, or Epsom *salt*, which liquifies in keeping, and running off in form of a fluid, leaves the rest of a good taste. In general, *bay salt* is much fitter for use, after it has been kept some time in a dry place, than when it is first made.

From the accounts already given of the *bay salt* of other countries, and the manner of preparing it, it seems evident, that our being obliged to purchase it of other nations is the effect of our want of application to the making it ourselves; since it is evident that it may be very well made, both in England, and in many of our American colonies. *Brownrig* of Salt, p. 202.

In England, a very advantageous sort of works might be set on foot in the following manner. A number of *salt* pits should be made in a row in the marsh, and their bottoms lined with plaister, or some strong cement that will not easily break up; and by this caution, the *salt* may be drawn white and pure like the Portugal kind, not grey like the French. Over each pit covers should be made of thin boards, or rather of canvas painted white, and stretched on frames of wood, and these should be fixed to strong posts, erected on the north side of the pits, and contrived to be easily drawn back to them, in the manner of draw-bridges. These covers, thus fixed, may be let down over the pits, in manner of a shed or penthouse, in rainy weather, to keep the brine from being diluted with fresh water; and in dry weather they may be raised almost to a perpendicular, but inclining a little toward the south, so as to form a wall with a south aspect; and thus they would serve for a double use, being a covering to the pits in rainy weather, and reflectors of the sun's heat in fair. The reflexion of so large a body of the sun's rays, in the course of a bright day, would greatly promote the evaporation of the brine; and the hinges, on which the reflectors turn, being placed at ten inches from the ground, when the reflectors stand upright, there will be a space under them, through which the air will continually flow in a brisk current, and this will greatly promote the evaporation of the water.

The passages of communication between the pits must be narrow and winding, and must be wholly stopped up in wet weather, that no fresh water run into the brine. This channel should be covered also with boards, and at the entrance of the pits there must not be a pond, as is the custom in France, but only a narrow covered trench, running parallel with the side of the pits which is opposite to the reflectors; and the pond, which forms the entrance of the pits in the French *salt* marshes, must in these be detached from them, and instead of it, there must be formed a fourth brine pond, communicating with the third by a long and narrow channel.

If these contrivances should be reduced to practice in England, the *salt* will probably crystallize much faster there than in the French marshes, and the brine may be kept as deep, and even deeper than in the French pits; and a shower of rain will only retard the work for the small time in which it is falling: whereas, in the French works, it throws them back three or four days, as no *salt* can be formed till all the water it brought be evaporated.

Four cisterns may be dug adjoining to the brine pits, to admit the brine in the *salt* ponds, when the weather is very rainy; and as to the *salt* water in the reservoir, if it should be found necessary to preserve it from rain in cisterns, when so much rain falls, as to make it fresher than sea water, it may be let out, and sea water admitted in its place. And in order to promote the evaporation, and to make the *salt* water in the reservoir fitter to supply the first brine pond with brine of a due strength, it may be proper, by means of a small fire engine, continually to force up the *salt* water in the reservoir, as often as occasion requires, and by means of a diverger, fitted to the engine, to make it descend again into the reservoir like a shower of rain; by which means, the evaporation of the watery vapours will be greatly promoted, after much the same manner as is practised at several of the *salt* works in Germany, where the brine is very weak. *Brownrig* of Salt, p. 209.

Thus by augmenting the force of the sun's heat, and of the air, by promoting the evaporation of the watery vapours, and preventing the brine from being diluted with rain, it is very probable that, during the summer season, double the quantity of *salt* might be prepared at an English work with these contrivances, that is now usually prepared at a French *salt* marsh of equal magnitude.

Beside these methods of managing sea water, it is certain that very large quantities of *bay salt* might be prepared in England with great ease, from the natural brine of *salt* springs, and from the common fossile, or rock *salt* of Cheshire, dissolved in weak brine, or in sea water. Upon the whole, *bay salt* might thus be made here at a moderate price, and in sufficient quantities to supply both the nation itself, and all our colonies.

Brine SALT, a name given to that sort of common *salt* which is not made from sea water, but from the water of *salt* wells and springs. Great quantities of this *salt* are made in most of the inland countries, as in Germany, Switzerland, Hungary, and in some parts of France and England.

In Somersetshire, Cumberland, Westmoreland, Durham, and Yorkshire, there are many *salt* springs, but they are either too weakly impregnated, or situated where fuel is scarce, and for those, and other reasons, are not worked; but in other parts of England there are many rich and valuable *salt* springs, which are worked to great advantage: of these some are situated in Staffordshire, a great many in Lancashire, but the chief are those at Droitwich in Worcestershire, and Nortwich in Cheshire; about which last place there are many rich mines of fossile *salt*, above and beneath the beds of which the *salt* springs are usually found. At Nantwich, in the last county, there are also some *salt* wells, which have been of very long standing, being supposed by many to have been worked in the time of the Romans. The *brine* of these springs is found to differ very greatly in its strength and qualities; some yielding greatly more *salt* than others, and the *salt* extracted from some of them being found improper for many uses, for which that of others serves very well.

The *brine* of Barton and Nortwich is almost fully saturated with *salt*, a pound of it yielding six ounces of *salt*; that of Droitwich, Upwich, and Middlewich, contains about one fourth *salt*; some of the springs at Nantwich yield a sixth part *salt*, and those of Weston, in Staffordshire, afford only one ninth part. In England, we seldom boil weaker brine than the last; but in Germany, and some other places, where *salt* is scarce, they work springs, whose water is not higher impregnated than the common sea water, containing about $\frac{1}{36}$ *salt*. *Brownrig* on Salt, p. 98.

Beside common *salt*, the brine of most springs is impregnated with several other ingredients, the nature and properties of which ought to be known to every person who works the springs, in order to his managing his affairs with judgement. The brine of almost all *salt* wells has somewhat of a sulphureous principle mixed in it, as may be observed from its fetid smell, but this soon goes off in the boiling. Dr. Lister observes, that the brine of the pits at Droitwich stinks like rotten eggs, and will make any thing stink in twelve hours that is *salted* with it, whether it be flesh of young, or of grown animals; and yet the *salt*, prepared from this brine, is accounted the best of any inland *salt* in England, and seems indeed as good as any in the world. Nay, this very brine, after it has been boiled a little and clarified, proves an excellent pickle for beef, or any other meat, and for other domestic uses. Philos. Trans. Abr. Vol. 2. p. 362.

In the *salt* mines at Bevieux, in the Pais de Vaux, there are always found large veins of virgin sulphur, and the people who dig in them are often killed with damps and explosions. *Scheuchzer* of the Salt Works at Bevieux.

The brine of many of the English springs turns black as ink on being mixed with galls, and has in it a ferrugineous ochre, which subsides from it when it is exposed to the air in an open vessel, and falls to the bottom of the *salt* pan, as soon as the liquor begins to boil.

Brine of our *salt* springs has also usually mixed with it a very large proportion of what is called *scratch*. This is a sparry substance, analogous to that which forms the crusts in our teakettles, and the incrustations of moss, &c. in our petrifying springs. The Droitwich brine is very free from this, but the other brines of England, as well as those of Germany, and other places, all abound with it. At the bottom of some of our *salt* wells there is also found a black mud, which, when stirred up, blackens and infects the whole spring, like ink; and beside these ingredients, the brine of most springs is impregnated with several other *salts*, as well as the marine one. In all the German *salt* springs the liquor leaves a bitter ponderous fluid, resembling our bittern, produced in the working of sea *salt*, but seeming to partake more of the muriatic, or calcarious *salt*, than the bitter purging one of sea water, as may be concluded from the numerous experiments made on it by Hoffman. This is also observed by Leigh, in his Natural History of Lancashire and Cheshire, who observes, that beside the marine *salt*, the waters of the *salt* wells in those counties always contain a quantity of a calcarious nitre; and both the observations of Hoffman on the German brine pits, and the experiments made on the waters of several of our own springs, seem to confirm, that the waters of this kind in general contain among them other *salts*, or mineral alkalies. *Hoffman*, Obs. Med. Chym. Lib. 2. Obs. 18. *Leigh's* Nat. Hist. Lancashire, p. 44.

The

The antient methods of boiling brine into *falt*, in Chefhire and Worcefterfhire, are accurately defcribed in the tranfactions of the Royal Society; and the method, formerly ufed in Staffordfhire, is delivered in Dr. Plot's hiftory of that county; but the method, now generally ufed in England, is this.

The brine being received from the well into a large ciftern, is thence received, as occafion requires, into the *falt* pan. Thefe pans are of the fame form with thofe ufed in the boiling of fea *falt*, and ufually hold about eight hundred gallons: in fome places thefe are made of iron, and in others of lead. When the brine is put into the pan, a little blood is mixed with it, in order to clarify it, and leaden pans are placed at the corners, to receive the fcratch, or calcarious earth, that feparates from them in the boiling. An ounce of blood is fufficient for eight hundred gallons of brine. As foon as it is boiled, it is carefully fkimmed, and afterwards it is fuffered to boil very brifkly for fome time, till the *falt* is granulated; after this the fcratch is feparated, and the fire flackened, till the whole *falt* is formed.

When they have feparated the fcratch, and the *falt* is ready to cryftallize, they put into the pan feveral forts of feafonings, as they call them, fuch as ale, butter, and the like, which they fuppofe correct the bad qualities of the brine, and make the *falt* of a fmaller grain. After this they boil it very gently, and when as much *falt* is formed, as will fill two or three of their wicker bafkets, they rake it up to the fides of the pan, and fill it into the bafkets, placing them over the leach trough, that the brine may drain into it from the *falt*. The *falt* taken out, they call a draught of *falt*, and the operation, a clearing of the pan. *Brownrig* of Salt, p. 104.

In this manner they draw the *falt*, and clear the pan five or fix times during each procefs, leaving at laft only a few quarts of brine at the bottom of the pan. The bafkets, into which they put the *falt* out of the pan, are called alfo *barrows*: they ufually contain about a bufhel of *falt*, and are of a conic figure, open at the bafe. The whole procefs of working a pan of brine ufually lafts about twenty four hours. After the *falt* has drained an hour or two in the bafkets, it is removed into the hot-houfe over the furnace, where it remains four or five hours to be thoroughly dried, and is then taken out of the bafkets, and laid up for fale.

In all the Englifh *falt* works, the leach brine, which is what remains in the pan after the *falt* is cryftallized, and what drains from the *falt* in the bafkets, is not thrown away, as it is in Germany, but is added to the pan next to be boiled. And befide the *falt* made in this manner, they have, at moft of the Englifh *falt* works, a different kind, which they call *fhivery falt*. See the article SHIVERY *falt*.

They have alfo another kind of *falt*, made up in form of fugar loaves in fmall wicker bafkets, which is thence called *loaf falt*, or *bafket falt*. This is the whiteft, drieft, and fineft grained of any *falt*, and is therefore greatly efteemed at table. In preparing this *falt* they ufe fome refin, and other additions, to break the grain, and render it very fmall; others alfo, to this purpofe, boil it the more brifkly, and ftir it brifkly all the while. But in Chefhire, where the beft bafket *falt* is made, they ufe no particular procefs about it, but only take the third draughts of every pan, which always are the pureft *falt*; and they do not fuffer thefe to lie fo long in the pan, as when they make *falt* of a larger grain, but take it out before it can form large cryftals: by this means they have it of a fine fmall grain, and they then prefs it hard down into the wicker bafkets, and when dried in the ftove, they let it remain in the bafkets for fale. *Brownrig* of Salt, p. 107.

Not long fince Mr. Lowndes publifhed a method of greatly improving the Englifh *brine falt*, fo as to make it at leaft equal to the French *bay falt*.

The method is this. Let a brine pan, containing about eight hundred gallons of liquor, be filled with brine to within an inch of the top; then make and light the fire, and when the brine is juft lukewarm, put in either an ounce of blood from the butchers, or the whites of two eggs. Let the pan boil with all poffible violence, and as the fcum rifes take it off. When the frefh, or watery part is pretty well decreafed, throw into the pan the third part of a pint of new ale, or the fame quantity of the grounds of any malt liquor. When the brine begins to grain, add to it the quantity of a fmall nut of frefh butter, and when the liquor has ftood half an hour longer, draw out the *falt*. By this time the fire will be greatly abated, and fo will the heat of the liquor; let no more fuel be thrown on the fire, but let the brine gently cool, till a perfon can juft bear to put his hand into it; keep it in that degree of heat as nearly as poffible, and when it has worked for fome time, and is beginning to grain, throw in the quantity of a fmall nutmeg of frefh butter, and about two minutes after that fcatter throughout the pan, as equal as may be, an ounce and three quarters of common alum, pulverifed very fine; then inftantly, with the common iron fcrape-pan, ftir the brine very brifkly in every part of the pan for about a minute; then let the pan fettle, and conftantly feed the fire, fo that the brine may never be quite fcalding hot, yet always a great deal more than lukewarm; let the pan ftand working thus for about three days and nights, and then draw it, or take out the *falt*. The brine remaining, will, by this time, be fo cold, that it will not work at all, therefore frefh coals muft be thrown upon the fire, and the brine muft boil for about half an hour, but not near fo violently as before the firft drawing; then with the ufual inftrument take out fuch *falt* as is beginning to fail, and put it apart; then let the pan fettle and cool. When the brine becomes no hotter than one can juft put one's hand into it proceed as before, and let the quantity of alum not exceed an ounce and a quarter, and about eight and forty hours after draw the pan, and take out all the *falt*. *Lowndes*'s Brine Salt improved.

This is Mr. Lowndes's procefs only; he afterwards directs cinders to be chiefly ufed in preparing the fires, the better to preferve an equal heat, and by that means alfo he propofes faving a confiderable expence, afferting, that at prefent cinders are fo little valued in Chefhire, as to be thrown out into the highways. Mr. Lowndes adds, that in a pan of the fize before-mentioned, there may be prepared, at each procefs, fixteen hundred pounds weight of *falt* from the beft brine in Chefhire, and one thoufand and fixty-fix pounds from the ordinary brine of that county. This, as the procefs continues five days, is a little more than five bufhels and a half of *falt* a day, from the beft brine, and a little more than four bufhels a day from the ordinary kind. *Brownrig* of Salt, p. 106.

Marine SALT, the name given by writers on this fubject, exprefsly to that kind of common, or white *falt*, which is boiled from fea water, without any previous preparation.

This *falt* is only made in counties where great quantity of fuel can be had at a very low price, or where the fun has not force enough; and is therefore made in few counties of England, except on thofe parts of the Britifh coaft which moft abound in pit-coal. This has thence got the name of *Newcaftle falt*, and is exported to Denmark and Norway, and fome other countries, as well as fent to London and other parts of England.

The moft convenient works for the making this *falt* are conftructed in the following manner. The faltern is erected at fome convenient place near the fhore; it is a long and low building, confifting of two parts, one called the fore-houfe, and the other the pan houfe or boiling-houfe. The fore-houfe ferves to receive the fuel, and cover the workmen; and in the boiling houfe are placed the furnace, and the pan in which the *falt* is made. And in fome places they have two pans, one at each end of the building, and the fuel and place for the workmen is in the middle. The furnace opens into the fore-houfe by two mouths, and from thefe is carried up a wall to prevent the afhes from flying to the *falt* pans, and in this is a door of communication between the two houfes. The body of the furnace confifts of two chambers, divided from one another by a brickwork called the mid feather, which from a broad bafe terminates in a high edge nigh the top of the furnace, and by means of fhort pillars of caft iron fixed upon it, fupports the *falt* pan. The pans are oblong and fhallow, the common meafure being fifteen feet in length, twelve feet in breadth, and fixteen inches in depth; they are commonly made of plates of iron joined together with nails, and the joints filled with a ftrong cement; and the bottom of the pan is prevented from bending down, or changing its figure, by hooks faftened to ftrong iron bars which are placed acrofs it.

Between the fides of the pan and the walls of the boiling-houfe there runs a walk five or fix feet broad, where the workmen ftand to draw out the *falt*. The roofs are wood, and are faftened with pegs of wood, nails mouldering away into ruft in a few months.

Not far diftant from the faltern on the fea fhore, between full fea and low water mark, they make a little pond in the rocks, or with ftones in the fand; this they call a *lump*, and from this pond they lay a pipe; through which, when the fea is in, the water runs into a well adjoining to the faltern, and by this well they pump it into troughs, by which it is conveyed into their fhip or ciftern, in which it is ftored up till they have occafion to ufe it.

The ciftern is built clofe to the faltern, and may be placed moft conveniently between the boiling-houfes on the backfide of the fore-houfe. It is made either of wood, brick, or clay, and fhould be covered with a fhed, that the *falt* water in it may not be weakened by rains, and fhould be placed fo high that the water may conveniently run out of it into the pans. When the fea water has ftood in the ciftern till the mud and fand are fettled from it, it is drawn off into the *falt* pan; and at the four corners of the *falt* pan, where it is fupported by the brick work, and confequently the flame does not touch its bottom, there are placed four fmaller leaden pans and fcratch pans, which for a *falt* pan of fifteen feet, are ufually about a foot and half long and a foot broad, and three inches deep. Thefe have a bow or circular handle of iron, by which they may be drawn out with a hook when the liquor in the pan is boiling.

The *falt* pan being filled with fea water, a ftrong fire of pit-

pit-coal is lighted in the furnace, and then, for a pan which contains about fourteen hundred gallons, the *ſalt* boiler takes the whites of three eggs, and incorporates them all with two or three gallons of ſea water, which he pours into the *ſalt* pan, while the water contained therein is only lukewarm, and mixes this with the reſt by ſtirring it about with a rake. In many places they uſe inſtead of eggs the blood of ſheep or oxen to clarify the ſea water; and in Scotland they do not give themſelves the trouble of clarifying it at all. As the water heats, there ariſes a black frothy ſcum upon it, which is to be taken off with wooden ſkimmers. After this the water appears perfectly clear, and by boiling it briſkly about four hours, a pan loaded in the common way, that is about fifteen inches deep, will begin to form cryſtals upon its ſurface. The pan is then filled up a ſecond time with freſh ſea water; and about the time when it is half filled, the ſcratch pans are taken out and emptied of a white powder, ſeeming a kind of calcarious earth, which ſeparates itſelf from the ſea water, during its boiling before the *ſalt* begins to ſhoot. When theſe have been emptied, they are again put into their places, where they are afterwards filled again. This powder being violently agitated by the boiling liquor, does not ſubſide till it comes to the corners of the pan where the motion of the maſs is ſmaller, and it there falls into theſe pans placed on purpoſe to receive it.

The ſecond filling of the pan is boiled down after clarifying in the ſame manner as the firſt, and ſo a third and a fourth; but in the evaporation of the fourth, when the cryſtals begin to form themſelves, they ſlacken the fire, and only keep the liquor ſimmering. In this heat they keep it all the while that the *ſalt* is granulating, which is nine or ten hours. The granules or cryſtals all fall to the bottom of the pan; and when the water is almoſt all evaporated, and the *ſalt* lies nearly dry at the bottom, they rake it all together into a long heap on one ſide of the pan, where it lies a while to drain from the brine, and then is put into barrows and carried to the ſtore-houſe, and delivered into the cuſtody of his majeſty's officers. In this manner the whole proceſs is uſually performed in twenty-four hours, the *ſalt* being commonly drawn out every morning. This is the method in moſt of our *ſalt* works, but in ſome they fill the pan ſeven times before they boil up the *ſalt*, and ſo take it out but once in two days, or five times in a fortnight. In the common way of four boilings, a pan of the uſual ſize, containing one thouſand three hundred gallons, they draw from fifteen to twenty buſhels of *ſalt* every day, each buſhel weighing fifty-ſix pounds.

When the *ſalt* is carried into the ſtore-houſe it is put into *drabs*, which are partitions, like ſtalls for horſes, lined at three ſides, and the bottom with boards, and having a ſliding board on the foreſide to draw up on occaſion. The bottoms are made ſhelving, being higheſt at the back, and gradually inclining forward; by this means the brine remaining among the *ſalt*, eaſily ſeparates and runs from it, and the *ſalt* in three or four days becomes ſufficiently dry; in ſome places they uſe cribs and barrows, which are long and conic wicker baſkets for this purpoſe, and in ſome places wooden troughs with holes in the bottom. The ſaline liquor which remains from the making of *ſalt* is what is called bittern. See the article Bittern.

The ſides of the pans in which the *ſalt* is made, are ſoon cruſted over with the ſame ſort of matter formed into cakes or cruſts, that falls in powder into the ſcratch pans; this the workmen call ſtone ſcratch; they are obliged to cleanſe the pans of it once in a week or ten days, otherwiſe they will be burnt: in England they do this with iron picks, but at Hall in Saxony they have a much better method; for they then take out the pans, and turning them bottom upwards, burn ſtraw under them, by which means the matter of the cruſt looſens itſelf, and after this it falls off on being ſtruck with a mallet or hammer. *Brownrig* of Salt, p. 62.

In Lancaſhire, and ſome other parts of England, ſea *ſalt* is made in this manner: they pare off, in dry weather, in ſummer, the ſurface of the flats, which are covered at full ſea, and bare when the tide is out. When they have procured heaps of this they put it into troughs, and pour freſh water on it; this waſhes off the *ſalt* that hung about the ſand, and is received ſo impregnated into veſſels ſet underneath the troughs. So long as this liquor is ſtrong enough to bear an egg they put on more water; when an egg ſinks in it they throw the ſand out of the troughs, and put in freſh from the heaps. The water thus impregnated with *ſalt* they boil in leaden pans, and evaporate to a dryneſs, the *ſalt* remaining behind. *Ray*'s Engliſh word, p. 179.

Rock Salt, a name given by the common people of England to the foſſile *ſalt*, or *ſal* gem, found in ſeveral parts of the world.

It was in the year 1670 that we firſt diſcovered the mines of *rock ſalt* in Cheſhire, where it was accidentally found on the lands of Mr. Marbury, of Marbury, in that county, in boring for coal. It lay there thirty-three or thirty-four yards from the ſurface, and there iſſued from it a vigorous ſharp brine ſtronger than any of the Cheſhire *ſalt* ſprings before known afforded. Since that many other mines of it have been found in the ſame county, and a great many are now worked by a company of proprietors, and yield vaſt quantities of *ſalt*; but this is eſteemed unfit for domeſtic uſes in its natural ſtate, and for that reaſon the proprietors uſe the method practiſed in Poland, Hungary, and many other places on the coarſer *rock ſalt*, that is, the refining it, by diſſolving it in weak brine, and then boiling it into *ſalt* again; this is done with great quantities on the ſpot; and beſide this great quantities are carried in the rough ſtate to Liverpool, and there refined with the water of the river Merſey at full ſea, or elſe ſhipped at Liverpool, and thence tranſported to other parts of England and Ireland, where it is wrought into *ſalt* with ſea water.

The *rock ſalt* refined upon the ſpot is alſo exported to Ireland; and in times of war, to our American colonies, when they cannot have bay *ſalt*. The works where they refine the *rock ſalt* are called refineries, and the *rock ſalt* is broken ſmall and put into leaden ciſterns, where it is diſſolved cold in ſea water. When the ſolution has ſtood a day and night to ſettle, it is drawn off from the ſediment into the *ſalt* pan, and refined into *ſalt* in the ſame manner that common brine is boiled up. The ſame additions are uſed in the clarifying it, and the ſcratch or calcarious matter falling from it, forms a cruſt as in the other works. The brine left in the pans after the *ſalt* is taken out is not thrown away, but is added to the next quantity put into the pan, and ſo on to the end of the works. *Brownrig* on Salt, p. 139.

In Hungary, near the city of Eperes, they have a very remarkable mine of this *ſalt* which ſupplies the whole country thereabout. The mine is near two hundred fathoms deep, and in the greateſt part is ſunk through earth, not through rock. The veins of *ſalt* are ſo large, that there are many blocks of it weighing two thouſand pounds, ſome of ten or more. The *ſalt* is uſually hewn out into long ſquare pieces of about two feet, and is afterwards ground between two grindſtones, to reduce it to a powder fit for uſe. Though the mines of *ſalt* are uſually cold and damp, yet the *ſalt* itſelf being very ſolid, and in the rock or maſs, is ſeldom much affected by the dampneſs. The *ſalt* in many of the mines is not of a fine white, but ſuch as is of a duſky grey in the maſs, often becomes very white when powdered, and made fit for uſe.

Salt upon Salt, a name given to a kind of common *ſalt* prepared by the Dutch, of great uſe in preſerving herrings and other fiſh, and to which they principally owe their advantages in the herring trade. The Dutch prepare two kinds of refined *ſalt*, one of a ſmall grain, intended for the uſe of the table, and called butter *ſalt*. They export large quantities of this to the countries upon the Rhine, and into other parts of Germany. The other kind is a very ſtrong and pure *ſalt*, and is of the largeſt grain of any boiled *ſalt*, now made: this laſt they call the St. Ubes or Liſbon *ſalt*, from its reſemblance to the pure bay *ſalt* made in thoſe places.

The *ſalt*, which they refine, is altogether marine bay *ſalt*, and they chiefly have it from France and Spain; but they find, by experience, that any one kind of bay *ſalt* does not anſwer their purpoſes, ſo well as two or more kinds; they therefore frequently mix three parts of Cadiz *ſalt* with one part of that of Souſton, which is of great ſtrength, but very dirty, and of a green colour, and does not coſt above half the price of the Spaniſh *ſalt*; for diſſolving the bay *ſalt*, they uſe ſea water, which they bring in lighters to Dort and Rotterdam from below the Brill or Helvoet; out of theſe lighters it is craned into cellars, and is thus impregnated with bay *ſalt* to a certain degree of ſtrength, which they determine by hydrometers made for that purpoſe. After the heavy droſs of the *ſalt* is ſubſided to the bottom of the cellar, the clear brine is pumpted up into the *ſalt* pan through a mat, which retains the light ſcum, ſtraws, or other impurities, which floated on the ſurface of it. Theſe *ſalt* pans are of iron, of a round figure, and commonly forty feet in diameter, and eighteen inches deep. Theſe pans are placed over a hearth furnace, and the only fuel they uſe in the boiling the *ſalt* is dry turf. The fire is kept up ſo high, that the liquor boils briſkly all the time, and if any ſcum ariſes, they carefully take it off, but they uſe no clarifying mixtures. A little before the *ſalt* begins to granulate, they add to the pan a lump of butter, of the bigneſs of a walnut, and half a pint of ſour whey, which has ſtood at leaſt half a year. When theſe things are perfectly mixed in by a good ſtirring, they ſhut the doors and windows of the houſe, that no air can blow in cold, and the houſe is kept thus hot all the time that the *ſalt* is forming. This method is not new, or peculiar to the Dutch works, for Agricola deſcribes an apparatus of boards, to keep the cold air out of the *ſalt* pan all the time that the *ſalt* is forming; and the Germans uſe it in many places at this time.

It is out of this ſame brine, and by the ſame proceſs, that they make the table *ſalt* and the ſtrong *ſalt*; only toward the end of the proceſs they make this difference, if the pan is to be wrought into table *ſalt*, the brine is kept gently ſimmering during the whole operation, and all is finiſhed in twenty

twenty four hours; but if it be to be made into the ftrong *falt*, they flacken the fire to fuch a degree, that the operation takes up three days. In both cafes they let the *falt* remain in the pan till the whole is finifhed; they then rake it out with wooden rakes, and after it has drained a while in wooden drabs, it is fit for ufe. The mother brine, of which there always remains a large quantity in the pan after the ftrong *falt* is made, as alfo the drainings of the drabs where the *falt* is put, is referved to be boiled up into table *falt*; but the mother brine of the table *falt* becomes more fharp and bitter after every procefs, and is finally thrown away. *Brownrig* of Salt, p. 142.

Sea SALT. The common *fea falt* is deftructive to almoft all plants, except thofe which naturally grow in the fea water, or on the fhores. Mr. Tull has invented a method of determining how far the horizontal roots of plants run, by burying *falt* at a diftance from them. See the article ROOT. It has been thought by fome that this was an uncertain trial, becaufe, though the roots reaching the *falt* were deftroyed by it, yet the plant would continue to be fupplied by others, and would not perifh; but this is erroneous, for the roots of plants coming where *falt* is, are not killed by it, but they draw juices from the earth where it is buried, and carry it with thofe juices to the plant, and by this means they fail not to kill it. One root, thus coming in the way of *falt*, is able to kill the whole plant, though it have ten thoufand roots, takiog good nourifhment from other places.

This is finally exemplified in the growing of mint in water. If a ftrong and vigorous fhoot of mint, growing in fimple water, be placed near a glafs of *falt* water, and one fibre of its roots be raifed out of the glafs in which it ftands, and plunged into the *falt* water, the whole plant will be killed in a few days by this *falt*, taken in by this fingle fibre, though all the reft are takiog in proper nourifhment from the frefh water all the time. The fame thing happens, if one of thefe roots be taken up and tied in a bag, containing a fpoonful of dry *falt*; the *falt* will foon grow moift, and the plant will be killed. On tafting of the leaves of the plants thus killed, they are found to have imbibed a larger quantity of *falt* than could be conceived from fuch a fmall and fingle root, the whole ftalk, leaves, and every other part of the plant, tafting ftrong of *fea falt*. *Tull*'s Horfe-hoeing Hufbandry. See *Marine* SALT, fupr.

Egra SALT. See the article EGRANUM *fal*.

Effential SALTS. See *Salts of* PLANTS.

Fixt SALTS. Mr. Homberg has given, in the Memoirs of the Paris Academy, a very curious paper of the fubject of volatilizing the *fixt falts* of plants. He obferves, that the *fixt falt* of any plant is a *faline* matter, which has already loft in the fire all, or the greater part at leaft, of the volatile matter contained in the plant it is obtained from, as its phlegm, acid fpirit, urinous fpirit, its effential oil and urinous *falt*; and that its figure is in fome degree that of a fpunge, the pores of which being always open, are ever ready to receive again fuch forts of volatile fubftances, as the fire has before driven off from them; and that art may in fuch a manner add thefe its deprived parts to it again, that the concrete fhall lofe its fixity, and become volatile, as the whole was in a great meafure before. The whole of this operation confifts in the adding to the lixivial *falt* one or more of thofe volatile fubftances, the lofs of which gave it its prefent form. Thefe are to be introduced into the *falt* by repeated cohobations, which are to be continued till fo much volatile matter is added to the fixt, that the whole becomes volatile together; the naturally volatile particles being mixed in fuch proportion, as to be able to carry up the fixed in vapour with them. The feveral volatile fubftances of plants are of different kinds, and confequently require different operations, to make them mix with the *falt*. Tartar may very well ferve as a general inftance in this cafe, and the manner of introducing into its *fixt falt* thofe principles, of which the fire before divefted it, and by this means rendring it volatile, may ferve as a fpecimen of the manner of doing it in all the reft: but as *falt* of tartar, and all other fixt vegetable alkaline *falts*, however well purified, always contain a great deal of earth, the feveral volatiles employed act differently on this, according to their feveral natures; fome carrying it all up in vapour, others carrying only a part of it, and leaving at the bottom of the veffel more or lefs of an earthy matter, infipid to the tafte, and wholly divefted of its alkaline *falt*; every particle of which, even in this cafe, has been volatilized, and raifed by the fire.

The alkaline *falt*, thus volatilized, appears alfo, according to the different fubftances employed, in very different forms; fometimes in that of a *faline* liquor, fometimes in an acid, and fometimes in ao urinous fpirit: fometimes alfo it becomes changed into a volatile *fal falfus*, fometimes into an acrid and fœtid *falt*, and finally, fometimes into a volatile aromatic one. The firft matter which fire drives out of tartar, or any other vegetable fubftance, is its phlegm: this being mere water, one would think at firft fhould be little able to change fo fixed a fubftance as *falt* of tartar into a volatile one; but when we farther confider the great power of water, when put in action by the fire, and that this agent is the caufe of fome of the greateft changes that happen in animal and vegetable bodies, and perhaps of every thing of this kind that paffes in our earth, we fhall not wonder that it may be made, by the help of fire, one of the agents capable of raifing, or volatilizing a part at leaft of *falt* of tartar; but as phlegm is the leaft active of all the principles which chemiftry feparates from bodies, or at leaft acts upon the others the moft flowly, and with the leaft violence, the method of volatilizing part of *falt* of tartar by means of this, muft naturally be more tedious than by any of the other principles; yet it is to be done with time by this, as well as by the other.

The thing that put Mr. Homberg upon this courfe of experiments was, as he candidly acknowledges, an accident. He was difpleafed with the Venice foap, with which he fhaved himfelf; and endeavouring to mend it, he cut it into thin flices, and after drying it three months in the fhade, he powdered it in a mortar, and wetted it into a pafte again with oil of lavender and fpirit of wine; and in continuing his trials to this purpofe, he at length found part of the *falt* of the foap become volatile.

It is very well known that foap is made of the *falt* of kali, or pot afhes and oil. On the event of this experiment, Mr. Homberg proceeded to judge, according to the known rules of chemiftry, that oil, of which the volatile *falts* are generally fuppofed to borrow their volatility, being intimately mixed with the fixed alkaline *falts*, as here with that of the kali, might render them all volatile, as in this inftance; for that in this ftate they were no longer alkalis, their pores being now not open, but filled to the utmoft wi.h tbe particles of oil. All oils contain alfo an acid, and that acid being mixed with the alkali *falt*, the whole on this muft ceafe to be an alkali, and become a middle, or neutral *falt*, fuch as common fea *falt*; but then as the acid is not, in this cafe, joined to the alkali, but by the means of oil, and accompanied with oil, this new found neutral *falt* muft neceffarily be of an oily, or a fulphureous nature.

In carrying on this idea, and trying by chemical experiments all the objects it offered, Mr. Homberg, in fine, found, that in order to volatilize the *fixt falts* of vegetables, it was neceffary to begin, by converting them into foap; then to wait for the fhooting of certain cryftals, or bright points, which would appear upon the furface, and that thefe cryftals were a neutral *falt*, volatilized of itfelf by the mere operation of nature: after this the matter is to be moiftened with a new liquor, and then fet upon the fire, and that thus there would be a new appearance of volatilized *fixed falt*; and the repeating this procefs feveral times, affords always, at length, a very large proportion of the *fixed falt*, no longer fuch, but truly volatilized. The choice of a proper liquor, for the wetting the matter, is a thing of no fmall confequence. Water is, of all others, the leaft proper, and oil appears the moft fo; and of the different oils, thofe drawn by diftillation are much more effectual than the common expreffed ones. The great reafon of this is, that the liquor ought not only to be the moft volatile that may be, but it muft be alfo fuch, as will moft intimately unite with *falt*. Spirit of wine is very excellent for the purpofe, but would be much more fo, did it not want this laft quality.

Mr. Homberg, by various trials, carried at length this attempt to fo great a height, that he was able to volatilize nearly one half of *falt* of tartar, or of any other volatile *falt*. The new *falt* often appears in a dry form, the oil, which is employed in the making it, preferving it from the effect of humid vapours, which would otherwife have refolved it into a liquor. Mem. de l'Acad. Par. 1714.

Foffile SALT. The ifland of Tfongming, in the Eaft-Indies, affords the moft remarkable kind of foffile, or native dry *falt* in the world. The country is there, in general, very fruitful, but in certain parts of the ifland there are fpots of ground, of feveral acres, which appear wholly barren, yielding not the leaft appearance of any thing vegetable upon them.

Thefe fpots of ground tafte very *falt*, and abound in *falt* in fuch a manner, that they fupply not only the whole ifland, but a great part of the neighbouring continent. When the people fee the earth become dry, and covered with white fpangles, which are pieces of *falt*, they dig it up about a foot deep, and carry it away to the work places, where they put it into large wooden veffels of four or five inches deep, and many feet broad, fet a little flanting. They pour water upon it in thefe. When it has ftood a proper time they let it out, and add more, till all the *falt* is diffolved; then they boil this water in the common way, and extract the *falt* from it. It is very remarkable, that the fame pieces of land, which produce vegetables one year, will produce this *falt* another; and, on the contrary, the *falt* parts will fome feafons produce vegetables. The *falt* work there is a thing of great advantage to the inhabitants, and all the poor are, in the feafon, employed in it; the men in collecting and wetting the earth, and the women in boiling up the water, which they attend as carefully as the men. Obferv. fur les Cout. de l'Afie.

Glauber's Salt. See Sal *mirabile*, supr.

Salts *of Count Lagarais*, a name by which the French and some other nations call a preparation of vegetable bodies, invented by the gentleman whose name it bears, but very improperly called by him a *salt*.

The history of these preparations is this: in the year 1731, the Count de Lagarais shewed the French king some powders, which he proved to be very useful in medicine, and which he called the *essential salts of certain plants*. The method of making these was long kept a secret, but at length the discoverer publishing it to the world, it appeared that they were made by means of water only, agitated in a violent and continued manner in a close vessel with an instrument resembling a chocolate mill. Mr. Langelot had before attempted a resolution of this kind of vegetable, and other substances, by means of water and motion, but his was done by grinding them with a very small quantity of water at a time; whereas this of the Count's is by powdering the ingredients, mixing them with a large quantity of water, and breaking them to pieces by a continued motion of this sort of mill made with four vanes, or flaps of thin wood, which was kept for six or eight hours in a continual motion by means of a larger wheel, such as the lapidaries polish stones with.

There is no doubt but that the instrument, used by the Count, is of very great use, and that the result of the operation is a very valuable form of medicine; but it is not a *salt*, but an extremely fine extract, containing the gummy, resinous, and *saline* parts of the body, and is a form capable of being reduced to powder, and easily administered, as it contains the virtues of the plant it is made from in an extremely small compass, and is capable of ready solution in aqueous fluids. It is certainly a form of medicine worthy to be brought into practice, and must be a very proper way of administring the more bulky medicines to children, and persons of tender constitutions.

To give a proper view of the nature of these preparations, and their difference from the extracts made in the common manner, it may be proper to enter, in some degree, into the manner of preparing the two forms. The common extracts of the shops are made either from the juices of succulent plants, as houseleek, purslain, or the like; or from a strong decoction of the other drier plants in common water, which when separated from the coarser parts by subsidence, filtration, or the like means, are evaporated over a balneum mariæ to the consistence of a thick honey.

There will, in process of time, an essential *salt* separate itself from these extracts, and many plants have, in the decoctions, a large quantity of a fine substance, which will never be made to pass the filter: and the extracts, made by this means, contain the oil, the gummy and resinous parts of the plants, and their essential *salts*, though this is but in a very inconsiderable quantity. These are the common extracts of plants.

The method of making those extracts, called *Count Lagarais's salts*, is this. They choose a glass vessel, capable of holding six or seven pints, and having a wide mouth; into this they put an ounce of bark, sena, guaiacum, or whatever other vegetable they are to make the extract of, first reduced to a coarse powder. They pour on this two pints and an half of rain water, or distilled water, and then taking the vessel to the place where the mill is fixed, they raise it so high, that the body of the mill is in the middle of the liquor; they then cover the top of the vessel with a wet bladder, that the froth may not be thrown over, and then turning the large wheel, they make the mill move round very swiftly in the liquor for six or seven hours together; after this they let the liquor settle for an hour or two, till only the finer parts of the body remain suspended in it, and then pour it off into a number of flat China, or stone ware dishes, putting only a small quantity into each dish, and these they set in the sun, or over a balneum mariæ prepared on purpose; for should they attempt the evaporation in a sand-heat, the small quantity of extract in each dish would be burned. When the whole is evaporated to a dryness, there remains on the whole inner surface of the dishes a thin crust of an extract, which is to be separated by scraping it off with a piece of stiff paper, and reserved for use. This always breaks up in small scales, which have a very shining surface on that part where they adhered to the dishes, and it seems that this has given occasion to some to believe, that they were particles of real *salt*.

There is no doubt, but this method of procuring a powerful extract might be of great use, in regard to all those substances which water can have power to penetrate; but it is not easy to give credit to its being able to make the like valuable medicines from the metals, though that has been pretended. Gold and silver are pretended to be operated on in a powerful manner by it, but there seems a fallacy in this, since even iron itself, which is much more penetrable by water than those metals, yields but little virtue to it, two ounces of the filings of this metal yielding, with the utmost care and accuracy, only about four grains of a white earthy matter, which is also much more likely to be a part of the water than of the metal.

The *salts of the metals*, as the Count called them, which were prepared by this means, were always suspected to hold some *saline* quality, which they owed to the menstruum, which, whatever was pretended, was not simple water, and a strict examination of them always discovered a marine *salt* among them. It is true indeed, that according to Langelot's method of grinding, some leaves of gold were reduced, by the addition of a very small quantity of water, into a liquor, from which, on distillation, a few red drops were separated; but it is to be observed, that as Langelot's method is the grinding the substance with great vehemence, and for a long time, in an iron mortar, with a pestil of the same metal, there is reason to suspect, that what was found to come forth in red drops was a solution of iron, not of gold, as was pretended by those who first prepared them. It is not to be doubted, but the method of evaporation of Count Lagarais's medicines is of great use, since no other can so well retain the finer parts of the medicines. Mr. Geoffroy tried it on roses, violets, and some other flowers, and found great reason to wish that all the medicinal extracts could be prepared in the same manner; but the method is impracticable, when medicines are to be prepared for general use; for though the mills might be made to be moved in great numbers at once, by a current of water, and so this part of the work performed with tolerable ease, yet the evaporations, in such quantities, could by no means be made in any tolerable room, or time, and they must be evaporated as soon as made, since they very quickly turn four, and lose all their virtues. Mem. de l'Acad. Scienc. Par. 1739. See Extract.

Lixivial Salts. It may appear very natural, from considering the common method of making the *lixivial salts*, that they should be all of them one and the same substance; and as the greater part of them agree perfectly, not only in taste, smell, and colour, but even in their effects, in the nicest chemical operations, in which it appears wholly the same thing, whether one or another of them be employed; many, even of the most celebrated chemists, have positively declared that they are all the same, and Kunkell has positively asserted this on many repeated experiments, allowing them no other difference, than that some contain more, some less earth; and this he affirms not to be owing to the different species of the plant, but from certain accidents in the burning.

This account, however specious, is not true; for though there are many of the *lixivial salts* procured from different plants, which, on many trials, appear alike, yet there are some that greatly differ from the common kinds; as that of tamarisk, which wants the greatest of all their characters, in that it is no alkali, but a true *sal salsus*; and beside this, there are probably many other as remarkable differences in others, which happen not yet to have been observed. Mr. Bourdelin, of the Paris Academy, having observed, that among the *lixivial salts* some were greatly more, some greatly less alkaline, and this last mentioned kind not at all, determined to search minutely into their differences in this respect. In this attempt he tried the produce of a great number of different fruits and flowers of plants, many of which gave *lixivial salts*, considerably different from one another; but nothing more strengthened his opinion of the essential differences of some of them, than the *salt* of guaiacum, which proved to be little more an alkali than the *salt* of tamarisk, and which he is of opinion may be prepared in such a manner, as not to proye at all alkaline. Mem. de l'Acad. Par. 1728. See Lixivious, *Cycl.*

The opinion of the fixed *salts*, drawn by elixiviation from all plants, being the same, having greatly prevailed, Mr. Gmelin, of the Petersburg Academy, went through a multitude of experiments with the *salts*, made carefully from a great number of different plants, on a number of different liquors; some mineral acids, others solutions and impregnations of different substances; and by these he found that they had very different qualities, beside their differing greatly in the degree of their alkaline power, which had been looked upon as their essential character.

He observes, that these *salts* are not to be obtained pure by any means, except a violent and repeated calcination; and that this is not the method used with the several *salts* made for medicinal use, and consequently that they are all impure. The additional matter, which makes these *salts* impure, is either an earthy, an oily, an acid, or a volatile alkaline substance, according as the plant, while recent, abounded with one or the other of those principles, or as their mutual connexions with one another were more or less strong in each. As therefore the several species of plants are well known to abound with different principles, it must necessarily follow that the *lixivial salts*, obtained from them in the common way, must differ in their nature and properties, as the acid abounds in one, the volatile alkali in another, and the earth or oil in a third.

This difference unquestionably owes its origin to the nature of

of the different plants; but besides this it must be allowed, that there are several accidents by which the *salt* may also be rendered of a different nature, or at least its natural diversity from others may be encreased, and set in a stronger light. The different manner of burning the plant will occasion a great change in the *salt* it yields; and two different *salts* will be obtained, if one half of the same quantity of ashes be lixiviated with hot water, and the other half with cold. This has been fully proved by Stahl in his *Fundamenta Chemica*.

These are only accidental differences in the same *salt*; what Mr. Gmelin takes upon him to prove by experiment, is, that there are more real differences between the *salts* of various plants, and those wholly dependent on the nature of those plants, than had been before suspected.

That the *salts* of plants may be fairly compared together, it is necessary that they should all be made in the same manner; the fire should, in all the processes, be raised to the same degree, and the time of the plants remaining in it should be also ascertained, and the lixivium from each be prepared in the same uniform manner: thus the volatile parts of one plant will be no farther evaporated than of another, and the lixivia will contain an equal share of the principles of the several plants, proportioned to their several natures; for it is a certain fact, that if the lixivium of the same ashes be made in part with hot water, and in part with cold, the *salt*, obtained from that made with the hot water, will contain more of the earthy and oily parts of the plant, than that made with the cold.

The method of making a fixt *lixivial salt* of a plant, so as to retain as much as may be of the virtues of the plant, is this. Let the plant continue on fire without breaking out into flame, and let the fire be continued till it fall into ashes, but no longer, lest some of the volatile parts be driven off, which might have been preserved. Cold water, and not hot, should be used to make the lixivium, that the *salt* may appear in its proper form; and as the water of wells, rivers, and other places, differ greatly from one another, the water used for this purpose should be such, as has been previously distilled two or three times over, and so rendered perfectly pure, and kept in glass vessels, not in earthen, leaden, or wooden ones, lest it contract some adventitious particles. Now if the lixiviums of plants, made with all these cautions, are found to differ from one another, there is no room to doubt, but that the *salts* of those plants are really different one from another.

This evidently appeared from the labours of a Swedish chemist, whose papers fell into Mr. Gmelin's hands, and who had with all this care and caution prepared the *salts* of a number of plants; a copious table of the different effects of which, in different mixtures, is added to Mr. Gmelin's account: but not only the *salts*, but the very ashes of different plants, prepared in the same exact manner, are found to differ obviously to the senses. The ashes of mugwort, small centaury, chervill, and dill, are of a brownish grey; goats beard and lingwort afford white ashes; those of sanicle are whitish; those of Roman wormwood of a greenish grey; those of rue, agrimony, and saxifrage, brown; those of tansy of a dusky green; those of dodder of a fine green; eyebright, southernwood, common wormwood, and scabious, afford them grey; scurvygrass of a whitish grey; hyssop, yarrow, and sowbane, of a dusky grey; melilot and oak leaves, as also plantain, colts foot, pine tops, and fumitory, of a dusky brown; pennyroyal of a pale brown, with some spots of white; elder flowers, sage, and mother of thyme, afford yellow ashes; those of strawberry leaves are of a pale brimstone colour; those of catmint of a dusky red; of prunella brick coloured; of honeysuckle blue; of fern blackish; and those of St. John's wort, feverfew, origanum, and pimpernel, are all of a deep black.

The quantity of ashes, produced from an equal weight of different plants, is very different, some yielding a seventh part of their weight, others but a twelfth or thirteenth, and some particular plants much less than this; St. John's wort in particular yields but a twenty eighth part, and fern but a twenty fourth.

The lixiviums made from these different ashes were some colourless from the beginning, others at first were bluish, greenish, or of other colours, but these tinges all went off after a few days, and the liquor became limpid.

The lixiviums of the several plants are very differently acrid to the taste, though made exactly in the same manner and proportion, and those of some plants are not acrid at all; that of strawberry leaves has scarce any taste; that of the barba capræ, instead of an acrid taste, has a sweet one; and the lixivium of mother of thyme has no taste, by which it can be distinguished from fair water: the lixiviums of pimpernel, dill, and strawberry leaves, have a sulphureous smell; those of most other plants are wholly scentless. Act. Petropol. Vol. 4. p. 289.

SALTS *of metals*. See the article METAL.

SALT *of milk*. See MILK.

Mineral SALT. It has been for many ages a constant opinion among the chemists, that minerals contain no volatile *salt*. Mr. Homberg, however, found the means of preparing an acid mineral *salt*, in a dry form and volatile. This would dissolve in spirit of wine, and that solution being thrown on marble, fermented, and dissolved it in the manner of aqua fortis.

All the world knows that many mineral substances contain an acid, and that this is easily raised in distillation, and therefore is very volatile; but as this could never before be separated, otherwise than in a liquid form, they esteemed it something of a peculiar nature, and called it an acid mineral spirit, banishing the word *salt* from its name. But Mr. Homberg found, that if the acid spirit of any mineral was so embarrassed in the particles of some metal, as that it ceased to be fluid, that metal was always considerably increased in weight by it; and that if afterwards all the acid which had been added to it were again separated from it, there would remain a volatile *salt* in a dry form, and that this *salt* if dissolved in spirit of wine, or in common water, made an acid liquor, which would dissolve all alkalies with an ebullition: from this, he says, it is plain, that the minerals have a volatile *salt*, as well as the animals or plants; which last were also long supposed to want it, and the volatile *salt* supposed peculiar to the animal kingdom: from this also it very plainly appears, that the acid spirits of minerals, as they are called, are in reality no other than these volatile *salts* dissolved in their own phlegm.

The method of procuring this *salt* may be seen in the following instance. Take two ounces of fine silver, dissolve it in five ounces of spirit of nitre; pour this solution, while hot, into a pint of river-water, in which there has been before dissolved as much sea *salt* as it can contain, the silver will precipitate itself in form of white scales. Wash this precipitate till it is insipid to the taste, and then dry it; it will, when perfectly dried, weigh two ounces and an half.

After this calcine in an iron vessel over a strong fire two or three pounds of fine tin, in which there is no mixture of any other metal. Take of this calx of tin well dried an ounce and half, mix this carefully with the two ounces and half of the calx of silver, perfectly dry also: put the mixture into a matrass, of which two thirds shall remain empty; expose this matrass to the naked fire, with its neck turned downwards, there will run into the neck of the matrass a black matter, which will immediately fix itself into a hard stone of a brown colour, this will weigh about an ounce and half; this stone is the calx of tin dissolved by the acids, which remain in the calx of silver; and the caput mortuum, at the bottom of the matrass, will be found to be the silver now divested of those *salts*, which it had carried with it from its dissolvent in the precipitation. This may be run into a mass by the copel, and no part of it will be lost.

Beat this brown stone to powder, let the powder be perfectly dry; then put it into a double vessel, sublime it according to art, and the result of the operation will be half an ounce of a volatile *salt*; this is to be rectified by re-subliming it two or three times over a very gentle fire, and it will then be a volatile and mineral *salt*, perfectly dry, of a fine white colour and transparent. The caput mortuum of this sublimation is the calx of tin. Mem. Acad. Par. 1692.

SALT *of mineral waters*. See the article HALCRYPTIUM.

Pine SALT. See the article PINE.

SALTS *of plants*. See the article PLANT.

Sedative SALT, a name given by the modern chemists to a *salt*, of the virtues of which they boast much. Those who first described it gave the process for making it in a very enigmatical manner; and their successors invented many different ways of preparing it. The truth is, that all mixtures of borax with the vitriolic acids furnish us with a *sedative salt*, as do also the mixtures of borax with spirit of nitre, or of sea *salt*.

Becher first gave the enigmatic account of it, which Homberg traced to its origin, and found the way of making it with the vitriolic, as Lemery did with the other acids. This *salt* is formed by sublimation, and is a congeries of saline flowers, not a little approaching to flowers of benjamin. These flowers are so light and fine, that they swim upon water, and will not dissolve in it unless it be made warm.

The *sedative salt* is a perfect *sal salsus*; it makes no alteration in the colour of the juice of violets, and has no sensible effect on the solution of corrosive sublimate, or on a solution of mercury in spirit of nitre for a long time; but it finally precipitates a yellow powder from it as the borax does; there is this difference, however, between this precipitate, and that formed by crude borax, that the powder precipitated by the *sedative salt*, does not as the other become white on washing with large quantities of water. These experiments shew this *salt* to be wholly analogous to tartarum vitriolatum, or to the Glauber's *salts* in its effects.

When the composition of which this *salt* is to be made is placed on the fire, there arise different liquors before the *salt* appears; the first is a phlegm of a fattish complexion, and with the smell of soap; this is succeeded by a turbid white liquor, along with which there arise some of the first flowers.

ers. This makes a solution of mercury in spirit of nitre muddy after some time, and finally precipitates from it a small quantity of a white powder. After this all the *salt* or flowers ascend; these flowers, dissolved in warm water, recrystallize themselves in it when cold, assuming the same form with that they had in the flowers, except that the combinations of particles are more dense and heavy.

The usual method of making this *salt* has been this. Take a glass retort, with a large neck, put into it four ounces of borax in fine powder, and pour on this half an ounce of common water to wet it into a sort of soft paste; then add to this an ounce and two drachms of concentrated oil of vitriol; place the retort in a reverberatory furnace, and give at first a small fire, which raise by degrees till the retort is red hot: there will pass over into the receiver about an ounce of aqueous matter; and after this the flowers, or *sedative salt*, will rise with a little more humidity; hence some part of the flowers will be dissolved in the liquor, and run over into the recipient, but the greater quantity will remain in form of a dry sublimation in the neck of the retort; they will finally stop up the whole orifice of the neck, and what arises after this usually forms a circle of a sort of glossy *salt*, about their bases, out of which the flowers seem to shoot.

They are composed of multitudes of fine thin blades, or flakes, and are easily brushed out of the neck of the retort with a feather; the glossy circle at the bottom of them may be dissolved in water, and recrystallized, and by this means all the *salt* will be procured.

Mr. Geoffroy the younger has given, in the memoirs of the Paris academy in 1732, an account of a way of making this *salt* by solution and crystallization alone, without the trouble of distilling; he has also summed up the several other ways of making it with blue and white vitriol, but the method here mentioned is that by which the chemists now make it. Mem. Acad. Par. 1732.

Shivery SALT. See the article SHIVERY.

Vitreous SALT, in chemistry, a term used by some modern chemists for a kind of *salt*, which till of late has wanted a name, and which is found in and separable from the fixed alkaline *salts* of vegetables.

It is bitter, hard, fixed, and not alkaline, and of a crystalline or glossy appearance.

The method prescribed by Boerhaave for the procuring it with most ease, is this: put six pounds of the best pot-ashes into a clean glass, add thereto twenty pints of cold rain water; stir them together with a stick, and suffer the whole to rest. When the ashes are thoroughly dissolved, gently decant the clear lixivium; and there will be found at the bottom, mixed with the fæces, a number of small greyish granules, of a bitter taste, and of an almost glassy brittleness and hardness; these are the *salt* required, and contain no alkaline quality; but to obtain it in greater purity, dissolve six pounds of pot-ashes in fourteen times their weight of water; filter the lixivium while hot, and make it perfectly clear; then put it into a glass vessel ready heated, and moistened, and suffer it to stand; a dusky crust will soon begin to shoot to the bottom and sides of the glass, and will gradually become thicker and thicker; at length when no more appears to shoot, pour off the liquor, and there will remain behind a *salt* like the former, but purer, and in larger quantity: if the remaining lixivium be boiled a little, and set to crystallize again, it will afford a small quantity more of this *salt*; but after this it will yield no more; whence there seems to be only a certain and determinate quantity of this *salt* contained in the alkali. If this *salt* be put into a vessel of rain water and shook about, it does not dissolve, only the alkali washes off, and the *salt* remains purer than before; after this it is to be gently dried and kept. *Boerh.* Chem. P. 2. p. 42.

It is well known among the chemists, that genuine fixed alkaline *salts* can hardly be crystallized; and though some have produced this *salt* as a crystallized alkali, the fallacy of the pretext is evident, since this appears on trial to be no alkali at all; and it remains not less difficult than before to crystallize pure alkali, though a *salt* different in its nature from it, may be crystallized in a certain quantity from among it.

This *vitreous salt* never runs spontaneously in the air, nor does it easily dissolve in cold water; when boiled it requires a large proportion of water to dissolve it, and as soon as cold it easily separates itself from it again: it is lastingly bitter to the taste, and crackles very much when thrown into the fire: it is neither acid nor alkaline, nor approaches in its nature to any other *salt* hitherto known; but seems nearest of all others to resemble sandiver. This may suggest a query, whether the fire in producing the fixed alkali, does not at the same time produce this *salt* from vegetables; and whether by combining the sand and alkali together in glass-making, the fire does not again separate and throw up this *salt* in sandiver. Something of this kind seems to be the case, and a close inquiry on these principles may shew us why tartar, in the state of an alkali, does not afford this *salt*; for tartar proceeds from a subtile liquor, intimately fermented in all its parts. There yet remains the trying this *salt* on various bodies, by means of fire, to give a true knowledge of its nature, which is at present too little known. This is to be observed, however, that it differs so much from the alkali, in which it is contained, that the careful chemist, before he makes use of that alkali in any nice process, or experiment, ought carefully to separate this neutral *salt* from it. *Boerhaave's* Chem. P. 2. p. 100.

Fusible SALT *of urine*. This *salt*, otherwise called by some *sal microcosmi*, and *native salt of urine*, is extracted from *urine* in a particular manner.

It is best prepared from putrified human *urine*; but it may be prepared from fresh. A quantity of the *urine* of sound beer drinking men being putrified in a moderate heat, and then slowly boiled in glazed earthen vessels to the consistence of a syrup; if this liquor be placed in a cellar or cool place, in about four weeks time, or sooner in winter, crystals of a peculiar figure will be formed. But these being impure, must again be dissolved in a sufficient quantity of water, and filtered as hot as possible through grey paper, and the solution again put in a cool place, where in a few days crystals will again be formed much cleaner than the former. These being separated from the liquor and dried, the operations of solution, filtration, and crystallization, must be reiterated twice or thrice, till the *salt* becomes perfectly white and without smell.

Mr. Marggraff says, that 100, or 120 measures of *urine* give about three or four ounces of this *salt*, which always crystallizes first, and is easily distinguished from that which appears afterwards in crystals of a long and cubical form.

This *salt* is ammoniacal, but of a peculiar nature. It is a saline acid body. By distillation an urinous volatile spirit first rises. The residuum may be reduced by a violent fire into a pellucid white transparent mass like glass, of a very fixed nature, and from which neither acid nor any thing else can be separated, without the addition of some other matter.

This vitreous substance may be entirely dissolved in two or three parts of distilled water, and is thereby changed into a transparent liquor, somewhat thick, not unlike the concentrated oil of vitriol, and having the properties of all acids, such as fermenting with volatile and fixed alcalies, forming neutral *salts* with them, precipitating bodies dissolved in alcaline menstruums, and dissolving alcaline earths. It does not dissolve gold nor silver; and copper, tin, and lead little; but iron very strongly. It extracts a red colour from *cobaltum pro cæruleo*, in German, *blau farben-kobalde*, the mineral by which glass is tinged blue.

But this *salt*, in its dry state attracts metals with much more vigour, and with them produces several remarkable and singular phænomena; for all which, as also for the relation their *salt* bears to acid, alcaline and neutral *salts*, we refer to the learned author, who has also examined its effects on several solutions of terrestrial bodies. One most eminent property is, that mixed with the inflammable part of soot, and dissolved in a close vessel, it produces a phosphorus. An ounce of this *salt* of urine thus separated from its urinous part, and exactly mixed with half an ounce of soot, affords in this way a drachm of the best phosphorus. The residuum did not produce any when tried.

The learned author does not pretend to determine exactly the true origin of this *salt*, he thinks its acid may come into the human body from vegetable aliments. He has observed elsewhere that cresses, mustard, rocket, and even corn exposed to a very violent fire, produce a phosphorus. Hence he thinks this acid must be mixed with those substances; and the like may happen in other vegetables. He thinks this conjecture strengthened, because urine in summer, when people eat most vegetables, always produces this *salt* in the greatest quantity. *Marggraff*, in Mem. de l'Acad. de Berlin 1746. See also Miscel. Berol. Tom. VII. p. 341.

Spirit of SALT. This menstruum dissolves iron into a yellowish green liquor, and copper into one of a very deep yellow colour: tin dissolves in it with great violence and noise, and in great quantity; the solution becomes a thick but pellucid fluid: lead also dissolves in it; but after this solution has stood for some time, there always subsides to the bottom a white powder. Silver, if it is perfectly pure, does not dissolve in *spirit of salt*, but if it contain ever so little copper, as it is very seldom met with perfectly pure from that metal, its surface is then always corroded, and its colour sullied. *Spirit of salt* dissolves mercury into a limpid liquor; if diluted with water it does not dissolve the regulus of antimony; and if this regulus is dissolved by the most concentrated *spirit of salt*, if a little water be added, or it be only exposed to a moist air, it is reduced to a fine powder. Zink dissolves easily and perfectly in this menstruum. *Cramer's* Art of Assaying, p. 38.

SALT-*marsh*, *salina*, a place where *salt* is made, of which there are many natural ones in the hotter countries, where the sea exhaling the water of *salt* lakes, leaves the *salt* dry and ready for use at the bottom, without any art or labour of man to make it: thus in Muscovy and some other places there are whole fields of *salt*. See *bay* SALT, supr.

The countries, however, where this is not naturally performed, may effect it by art, and make *salines* or *salt marshes*, where they may use the sun's heat to great advantage. This is annually done to great advantage in France, and there is no reason why we may not do the same, either at home or in our American colonies, though it has not yet been attempted.

In order to make a *saline* or *salt marsh*, a low plat of ground must be chosen, adjoining to the sea, and distant from the mouths of large rivers, and this must be near some convenient harbour for vessels. The ground must be free from fresh water springs, and out of the reach of land floods, and if possible should have a clayey bottom; and finally, it must be well defended from the sea, either by natural or artificial banks of earth of a proper strength and thickness.

The ground thus chosen must be hollowed out to three ponds or receptacles. The first into which the sea water is usually admitted may be called the reservoir. The second receptacle, which is to be divided into three distinct ponds, communicating with each other by narrow passages, and containing brine of different degrees of strength, may be called the brine ponds; and the third receptacle is to be furnished with an entrance, between which and the brine ponds there is to run a long narrow and winding channel; the rest of it is to be divided into small and shallow pits, containing a very strongly saturated brine, which in them is to be converted into *salt*, and they may therefore very properly be called the *salt* pits.

The first receptacle or reservoir must have a communication with the sea by a ditch, defended on each side by walls of brick or stone, and made of such a depth, that by it all the water of the reservoir and other parts of the *salt marshes* may be able to run out at low water, and by it also the sea may be admitted into it at high tide. So that at neap tides the marsh may be filled with sea water to the depth of ten inches in the reservoir; and consequently, at higher tides, to the depth of two feet, when there is occasion to overflow the marsh, as is always to be done in the winter season, when there is no *salt* to be made; for, by this means, the wood work is kept from decay, and the clay bottom from injuries by frost. The ditch between the reservoir and the sea must have a flood-gate, by which the sea water may be admitted, retained or let out as occasion may require. *Brownrig* of Salts, p. 37. Phil. Transf. N° 51.

The several ponds or receptacles must not have all their bottoms upon the same level, but must be made of unequal depths, so that the first receptacle or reservoir may be eight inches and a half deeper than the *salt* pits in the third receptacle. The three brine ponds also situated between the reservoir and the *salt* pits must be of unequal depths. The next adjoining to the reservoir must be the deepest, and that which is nighest the *salt* pits the shallowest, but all of them must be shallower than the reservoir; and the three receptacles being thus constructed, the water standing at the same height in them all, and forming with its surface one continued plain, will be ten inches deep in the reservoir, when only an inch and half in the *salt* pits.

The length and breadth of the brine ponds and reservoirs are to be at discretion; but it is best to err in making them too large, and in general they ought to be so large as to furnish the *salt* pits with a constant supply of brine, fully saturated with *salt*; and, for this purpose, it is necessary to have them of different dimensions, in different countries, according to the degree of heat.

The bottoms of the reservoir and brine ponds are to be lined with any kind of lean and tough clay, or earth, that will hold water; and the French use a red, or blue clay, to be had in the neighbouring grounds. With them the blue always succeeds better than the red, which colours the *salt* much more; but in order to have a perfectly pure *salt* from this kind of manufacture, the bottom should be lined with some clean cement, which will hold water perfectly, and will not be easily broken up. Id. Ibid.

The *saline* or marsh being thus constructed; the saltmen, at the proper season of the year, open the flood-gate when the tide is out, and drain off all the stagnating water; when this is done, they repair the bottom of the marsh in several places, where it is found necessary, and cleanse the several receptacles from mud and dirt: after this they admit the sea water, at the next high tide, till it floats the whole marsh, and stands at about ten inches high in the reservoir. In a day or two most of the water in the *salt* pits is exhaled, and what remains is a very strong brine, they then let in more sea water at the two or three following tides; and so take care to admit as much water fresh into the marsh as has been wasted in vapour by the heat, constantly raising it to the height of ten inches in the reservoir, and consequently to an inch and half in the *salt* pits; and when the weather is extremely hot, or there are sharp drying winds, they fill them something higher than this.

All the parts of the marsh are thus supplied with water out of the reservoir, but the sea water which is let into the reservoir, is not confusedly let into the other water or brine of the ponds and *salt* pits; for, as the several parts of the work communicate only by narrow channels: it is provided, that the *salt* water flowing out of the reservoir never returns to it again, but gently flows along till it arrives at the second brine pond, and from that to the third, being forced forward by the sea water received from time to time into the reservoir: during this flow course, the watery fluid alway flies off in great quantity by exhalations, and the brine is continually preparing for crystallization as it flows along gently, growing all the way stronger and stronger, as it approaches the *salt* pits; so that when it at length enters these pits, it is fully saturated with *salt*; and particular care is taken to guard the entrance of the *salt* pits by a long and narrow channel, by which means the strong brine contained in these pits is prevented from returning back, and mixing with the weaker brine in the brine ponds; care is also taken, that the strong brine in the *salt* pits is spread out very thin, and exposed to the sun and air with a large surface, by which means the water more quickly exhales from it, and the *salt* is left concreted into crystals. These crystals, or *salt*, the workmen in France draw out every day, and dispose them at length together in a pyramidal heap, which they cover over at the top with thatch or straw, and so preserve them from the injuries of weather. Thus at a small expence and trouble a *salt* is prepared, which is found very fit for all domestic uses; and France is furnished with a very profitable article for exportation into other countries. *Brownrig* of Salt, p. 43. See *Bay* SALT, supra.

SALT-*petre*. There are some lands in Jamaica and our other American plantations, which are said to contain *salt-petre*; though there have been no works set up for the refining and preparing it. The earth containing it has been found to have very different effects on vegetables from those of common earth.

The sugar canes that grow on these spots shoot up much faster, and grow larger than in other grounds; but they rot very soon if not ground, and they do not boil so well into sugar as the others. Potatoes planted in these grounds are always found to be two months forwarder than others, but they must be used soon, otherwise they decay, the *salt-petre* eating away the skin, which is thinner on those roots which grow in this sort of ground than elsewhere; and the fleshy part of this beginning to rot and moulder away. The tobacco planted, on the same grounds, is greatly altered in its nature also. It grows up very quickly, and becomes robust and strong, but it will not be cured to so good a colour as that which grows on common earth, nor will it keep so well; many cargoes of this tobacco have wholly perished at sea, by the leaves mouldering away to dust. And it is reported, as a certainty, that this tobacco, when smoaked, flashes in the pipe with large flames. Phil. Transf. N° 33.

SALT *springs*. There is a copious *salt spring* in the neighbourhood of Durham, lost to the country, by its rising in the bed of the river Weare. It does not issue out of any one particular spot, but bubbles up from the mud and rocks for the space of forty yards in length, and about ten yards in breadth. It is best examined in dry seasons, in the middle of summer; for at this time the water of the river is all carried into another part of the channel, and this place left dry. The greatest quantity at this time is found to issue out of a hard rock. It is as *salt* as any of the Cheshire brines; and though but very small in quantity, in proportion to the size of the river, yet it gives a manifest saltness to the water a hundred yards below. The brine has been collected in summer by some curious people, and evaporated, and is found to yield a very useful *salt*, not like that of the common inland *salt springs*, which is our white basket *salt*, but rather like the bay *salt*, of a dusky colour, and not very pleasant taste, but as fit for all the uses of life as any other *salt*. The water of this spring, as it runs among the stones in summer tinges them all of a reddish colour, which is a property not common to other brine. Phil. Transf. N° 163.

In Cheshire, and many other counties, they make a great use of the water of these springs, as a manure for their lands. They let out the water of these springs for a certain time upon the lands, after there has been rain, and by this means the quantity of *salt* they contain is so blended with the rain water, that it is too weak to hurt the corn or grass, and yet is strong enough to kill worms, and other vermin.

The vegetables of all kinds are improved also by this, for there are no lands that fatten cattle sooner, than the pasture grounds which are thus, at times, overflowed by the *salt* water.

We have instances of a like effect of sea *salt* in small quantity, and but occasionally laid on, doing great good to pasture in those high pastures about Erith, which are only overflowed sometimes in spring tides. These fatten cattle of all kinds in a very surprising manner. It is a wonder that no body has yet attempted a regular manuring of land with *salt* upon this plan, for bay *salt* might be had at a very small price in time of peace, and a bushel or two allowed to an acre, would probably have all the advantages that these over-

overflowings of the high tides, and natural *ſalt* ſprings, are found to have. Some farmers have tried the ſcattering *ſalt* over their corn fields, as ſoon as ſown, in the quantity of two buſhels to an acre, and it is ſaid with good ſucceſs. *Mortimer's* Huſbandry.

SALTS *microſcopically examined*. Mr. Lewenhoek has opened a very extenſive field for microſcopic obſervations, in the evaporation of certain fluids, in which *ſalts* of various plants, and other ſubſtances of a like kind, had been diſſolved.

The fixed *ſalts*, in general, are ſaid by chemiſts to admit of no cryſtallizations at all; but this curious obſerver found, that on being evaporated in ſmall quantities before the microſcope, they each would ſhoot into extremely minute, but regular cryſtals, and thoſe often of various forms in the ſame *ſalt*; but that theſe varieties were only of a certain number, and that no other *ſalt*, but that to which they belonged, had them all in the ſame regular manner.

The ſophiſtications of *ſalts*, too common among our chemiſts, may be diſcovered by this means, and many other advantages may he obtained from it, as well as great amuſement, in the obſervation of the variety and beauty of the figures.

The moſt agreeable way of examining theſe *ſalts* is by the ſolar microſcope; but the moſt accurate, and fitteſt for making deductions from, is that by the common double microſcope. The way is to diſſolve a ſmall quantity of *ſalt*, of any kind, in water, and add to this about one fourth part of ſpirit of wine; this renders the whole a much leſs fit menſtruum for keeping the *ſalt* in ſolution, and conſequently it much more readily concretes from among it. A large drop of this liquor is to be laid on the ſurface of a thin and clear piece of glaſs, ſuch as may conveniently be laid upon the ſtand for receiving objects in this microſcope; then this glaſs is to be held till gently heated over a clear fire, and when it begins to evaporate, the glaſs is to be placed under the microſcope, and about a third magnifier uſed to examine it. The *ſalts* will ſoon be ſeen beginning to ſhoot, and will form themſelves under the eye into very beautiful figures; ſome reſembling branches of trees, others ruins and fortifications, and the like; but what are moſt to be depended upon, as eſſential to the *ſalt*, are certain little ſingle ſhoots, reſembling cryſtals; theſe are determinate in their figure, the others more vague and uncertain. Theſe will always be produced the ſame from the ſame *ſalt*, the others ſcarce twice from even the different drops of the ſame ſolution, alike in all reſpects. Philoſ. Tranſ. Nº 172. p. 1075.

Carduus Benedictus affords three different kinds of *ſalts*, or cryſtals, ſingle and perfect in their kinds; the one is a thin ſquare, another an oblong, and thicker body, terminated by a point at each end, and reſembling in miniature the perfect double pointed ſhoots of rock cryſtal; and the third a quadrilateral pyramid, of the ſhape of the cryſtals of common *ſalt*. The oblong double pointed ſhoots are the moſt numerous in this *ſalt*, and ſeem to be the perfect figure of the genuine and purer *ſalt* of the plant. They are ſo numerous and minute, that Lewenhoek ſays he ſaw as many of them in the quantity of a ſingle grain of water, as the eye can count ſtars in a clear night.

Theſe, as alſo the cryſtals of many other *ſalts*, continue regular while the water is about them, but as that evaporates they join together, and become confuſed.

Wormwood affords a great variety of figures in its *ſalt*. When this begins to ſhoot by the evaporation of the water, there are diſcovered a number of very ſmall double pointed ſhoots, reſembling the ſhape of a weaver's ſhuttle; after theſe there are found ſome ſquare ones, then ſome which have ſix angles, yet are flat and thin; ſome others reſemble triangles with the corners cut off, and ſome are large and oblong; others large and ſquare, and bordered round with the reſemblance of the cut edges of a looking glaſs.

Blue vitriol, beſide its own rhomboidal cryſtals which ſhoot firſt, affords afterwards many oblong ones. The firſt rhomboidal ones have no ſenſible thickneſs, but they grow larger and thicker every inſtant, while the eye looks at them. They are pellucid and colourleſs at firſt, but afterwards they by degrees become blue, as they encreaſe in thickneſs.

Oil of tartar, made by diſſolving the *ſalt* into a liquor by the humidity of the air, firſt ſhoots into oblong and cylindric, but very thin bodies, reſembling ſmall cuttings of hairs; after theſe there appear certain flat bodies, having either two oblique ends, or one end ſtrait, and the other oblique.

Ruſſia pot-aſh firſt concretes into figures like a weaver's ſhuttle, but theſe ſoon after enlarge, and loſe their form: after this there appear hexangular figures with broad baſes, reſembling ſome of the native diamonds and cryſtals; among theſe there are others oblong and flat, but truncated at each end, and ſome roundiſh; others approaching to that figure, but with ſeveral angles, irregular both in number and ſize.

Camphor forms regular cryſtallizations, approaching to a rhomboidal figure, having ſix perfect ſides, though generally irregular in bigneſs, and their thickneſs is generally equal to their breadth. Among theſe are many irregular ones; ſome ſhaped like the flint of a gun, and ſome broad at the baſe, and running to a taper and fine point. Philoſ. Tranſact. Nº 173. p. 1089. See Tab. of microſcopical Objects, Claſs 3.

SALTARELLA, or SALTARELLO, in the Italian muſic, is applied to triple time, the firſt note of which is pointed thus:

or

Airs in this kind of movement are ſaid to be in *ſaltarello*. Such are the Venetian forlanos, ſicilianas, ſome jigs and other gay dances.

SALTATIO *mimicorum*, in antiquity. See DANCE, *Cycl.*

SALTO, in the Italian muſic. See LEAP.

SALVIA, *ſage*, in the Linnæan ſyſtem of botany, makes a diſtinct genus of plants, comprehending the *horminum*, and *ſclarea* of Tournefort and other authors, as plants of the ſame characters, and properly of the ſame genus: the characters of which are, that the calyx is a one leaved perianthium hollow, ſtriated, larger and compreſſed above, with an erect bilabiated edge; the upper lip being divided into three ſegments, the lower into two. The flower is a ſingle petal in form of a tube, large, and compreſſed above, and labiated at the mouth; the upper lip is concave, compreſſed, bent, and rimmed round its edge; the lower is broad and trifid; the middle ſegment being large, roundiſh, and rimmed round the edge. The ſtamina are two filaments bifid from their middle; the two branches remote, and having an obtuſe ſinus, one branch being the longer, and hid under the upper lip of the flower, and on this the anthera is placed; the other is terminated by an obtuſe body, probably a nectarium. The piſtil has a quadrifid germen, a thread-like, and very long ſtyle, placed in the ſame direction with the ſtamina, and a bifid ſtigma. There is properly no fruit, the calyx or cup of the flower cloſing ſlightly, and containing in its bottom four roundiſh ſeeds. *Linnæi* Gen. Plant. p. 6. See Tab. 1. of Botany, Claſs 4.

The characters of this genus, according to Tournefort, are theſe. The flower conſiſts of one leaf, and is of the labiated kind; the upper lip is ſometimes only arched, ſometimes very much hooked, the lower is divided into three ſegments; the middle one being protuberant, not hollowed like a ſpoon, as in the claries. The piſtil ariſes from the cup, and is fixed in the manner of a nail into the hinder part of the flower, and is ſurrounded with four embryos, which afterwards become as many ſeeds of a roundiſh figure, which ripen in a tubular caſe, that was originally the cup of the flower. To theſe marks it may be added, that the ſtamina reſemble the os hyoides in animals. *Tourn.* Inſt. p. 180.

The ſpecies of *ſage* enumerated by Mr. Tournefort are theſe. 1. The greateſt yellow flowered mountain *ſage* with clary leaves. 2. The large broad leaved *ſage*. 3. The greater *ſage* with purple flower cups. 4. The greater *ſage* with changeable coloured leaves. 5. The great *ſage* with leaves variegated with green and yellow. 6. The three coloured ſilvery *ſage*. 7. The leſſer *ſage* with ſinuated leaves edged with yellow. 8. The roundiſh leaved *ſage*. 9. The broad leaved ſerrated *ſage*. 10. The wormwood *ſage*. 11. The berry-bearing *ſage*, or apple *ſage* of Candy. 12. The Candy *ſage* without apples. 13. The white flowered Candy *ſage* without apples. 14. The narrow leaved ſerrated *ſage*. 15. The leſſer auriculated, and not auriculated *ſage*. 16. The ſmall white flowered not auriculated *ſage*. 17. The leſſer *ſage* with variegated leaves. 18. The thin leaved Spaniſh *ſage*. 19. The lavender leaved Spaniſh *ſage*.

The common broad leaved *ſage*; or, as we uſually call it, from the colour of ſome of the leaves, red *ſage*, is a ſudorific and diuretic; it promotes the menſes, and is good in palſies, vertigoes, tremors and catarrhs; and mixed with honey, it is ſaid to be one of the beſt known cures for the aphthæ and eroſions of the mouths of children.

The ſmaller leaved *ſage* generally ſold among us under the name of *ſage* of virtue, has the ſame qualities in a greater degree.

SALUSANDRIA, in botany, a name given by ſome authors to the nigella, called in Engliſh *gith*, or fennel flower. *Ger.* Emac. Ind. 2.

SALUTATION, *ſalutatio*, among the Romans, was a daily homage paid by clients and inferiors to their ſuperiors.

Among the great the atrium was the place appointed for this purpoſe, but among people of middling condition the veſtibulum only. See the articles ATRIUM and VESTIBULUM.

This practice of *ſalutation* was not confined to the city, but took place in the army likewiſe, it being uſual for the private ſoldiers to go very early in the morning to *ſalute* their centurion, who at their head proceeded to *ſalute* the tribune, and then the tribune, with the reſt, went and *ſaluted* the imperator, or commander in chief.

The women too had their crowds of *ſaluters* attending them every morning. *Pitiſc.* in voc. *ſalutatio.*

The manner of receiving thoſe who came to pay their reſpects,

ſpects, was to receive thoſe of the better ſort with a kiſs, and the poorer ſort had a ſmall entertainment given them, and were even feaſted by ſuch as wanted to be thought more liberal than ordinary.

SALUTATORIUM, in nunneries, a place where the nuns receive the ſalutation of thoſe that come to ſee them. *Hofm.* Lex. univ. in voc.

Salutatorium is alſo uſed for the veſtry, or place where the biſhop was dreſſed, and received the ſalutation of viſitants before divine ſervice. Id. ibid.

SALUTIGERULI, among the Romans, were ſervants chiefly employed by the women in carrying ſalutations to one another. *Pitiſc.* in voc.

SAMALUM, in botany, a name by which Pliny and ſome other authors have called the *pulſatilla*, or paſque flower. *Ger.* Emac. Ind. 2.

SAMARRA, a garment worn by thoſe condemned by the Romiſh inquiſition to be burnt; ſuch are impenitents, and thoſe who confeſs themſelves guilty of hereſy, but repent, and renounce their errors before the execution.

It is a black kind of frock, made of ſackcloth, and painted with flames pointing downwards; ſometimes the unhappy ſufferer's picture is drawn to the life on it, and ſometimes devils are painted on it dragging, as it were, the perſon along with them to hell. It is otherwiſe called *ſambenito*, and *ſamaretta*. *Hofm.* Lex. univ. in voc.

SAMBAK, or ZAMBAK, in botany, a name uſed by ſome authors for the jaſmine, or common white jeſſamy. *Chabræus*, p. 112.

SAMBENITO, a kind of frock worn by thoſe who are condemned by the Romiſh inquiſition to be burnt. See the article SAMARRA.

SAMBUCA, among the antients, a triangular muſical inſtrument. *Pitiſc.* in voc.

SAMBUCUS, the *elder*, in botany, the name of a genus of trees, the characters of which are theſe. The flower conſiſts only of one leaf, and is of the rotated kind, and divided into many ſegments at the edges. The middle of the flower is perforated by the pointal of the cup, in the manner of a nail, and the cup finally becomes a berry, containing ſeveral oblong ſeeds.

The ſpecies of *elder*, enumerated by Mr. Tournefort, are theſe, 1. The common *elder* with black berries. 2. The common *elder* with white berries. 3. The racemoſe mountain *elder* with red berries. 4. The jagged leaved *elder*. 5. The dwarf *elder*, called *ebulus*, or danewort. 6. The dwarf ſhrubby *elder* with beautifully variegated leaves. 7. The jagged leaved *ebulus*, or danewort. *Tourn.* Inſt. p. 606.

SAMEL-*bricks*. See the article BRICK.

SAMIA *terra*, in the materia medica, an earth of the marl kind, found in the iſland of Samos, and much uſed both in medicine and in the pottery of the antients.

It is of two kinds, a white dull looking one, called the *collyrium ſamium*, and a browniſh and glittering one, called the *aſter ſamius*. *Hill's* Hiſt. of Foſſ. p. 38.

The *collyrium ſamium* is ſtill to be found in the place from whence they had it, and from whence it has its name; and is a very fine and pure earth, of a cloſe, equal, and regular texture, and yet remarkably light. It is of a fine bright white colour, and of a ſmooth, even, and gloſſy ſurface. It is ſoft to the touch, adheres firmly to the tongue, is eaſily broken between the fingers, and does not at all ſtain the hands, but drawn along a rough ſurface, leaves a fine clean white line. It melts ſlowly in the mouth, and does not ferment with acids. Theſe are the characters by which it is to be diſtinguiſhed from the white earths: to which may be added its manner of lying in the earth; which is not, as that of moſt of the other earths, in a continued ſtratum, or bed, but in the perpendicular fiſſures, and horizontal cavities in the ſtrata of ſtone, in the manner of the European earths, called the *medullæ ſaxorum*, but in ſubſtance very different from them all.

The antients prepared them by burning, waſhing, and then uſed them with ſucceſs internally in hæmorrhages, and fluxes of all kinds, and externally in inflammations. They alſo uſed them, probably, both mixed together, and blended with ſome other viſcous earth, or clay, for the fineſt of their earthen ware. *Hill's* Hiſt. of Foſſ. p. 38.

The other kind of *Samian* earth, called *aſter ſamius*, is ſtill found in the place from whence they had it, and lies in the ſame manner in which they have deſcribed it, in an horizontal cavity between two rocks.

It is a looſe, lax, and crumbly earth, of a mixed colour, between a duſky white and a pale brown, and all over ſpangled with ſmall glittering particles. It is of a looſe and incoherent ſtructure, but uſually breaks away into flat pieces, and ſeems ſomewhat of an obſcurely laminated make. It is of a dry duſty ſurface, falls to pieces very readily between the fingers, and though it duſts the hands, does not at all ſtain them. It melts very readily in the mouth, and when thrown into water parts immediately, with a hiſſing noiſe, into a number of flaky pieces, and from thence moulders into a looſe powder. It makes no effervefcence with acid menſtrua, and when its glittering particles are ſeparated, and ſtrictly examined, they are found to be ſo many thin flakes of that ſpecies of foſſils, called *ſelenites*.

This, as well as the other ſpecies, or *collyrium*, was prepared by calcination and waſhing, and uſed by the antient phyſicians internally in fluxes and hæmorrhages, and externally in inflammations. It was alſo one of the moſt valued earths in the Roman pottery. *Hill's* Hiſt. of Foſſ. p. 39.

SAMIARII, among the Romans, were a kind of furbiſhers, who with Samian earth poliſhed the arms of the prætorian ſoldiers and emperor's life guards. *Pitiſc.* in voc.

SAMIR, a kind of worm, which, according to the fabulous ſtories of the Jews, was made uſe of by Moſes in fitting and poliſhing the precious ſtones in the ephod, and the two tables of the law. *Hofm.* Lex. univ. in voc.

SAMLET, an Engliſh name for a fiſh of the truttaceous kind, caught in Herefordſhire, and ſome other parts of England, and called by Willughby *ſalmulus*. *Willughby's* Hiſt. Piſc. p. 193. See SALMULUS.

SAMOLUS, in botany, the name of a genus of plants, the characters of which are theſe. The flower conſiſts of one leaf, is rotated, aad divided into ſegments at the edge. The piſtil ariſes from the cup, and is fixed in the manner of a nail to the lower part of the flower, and finally joining with the cup, it forms a ſhell, or capſule, which opens at the ſummit, and contains a great number of ſmall ſeeds.

The ſingle ſpecies of *ſamolus*, according to Mr. Tournefort, is the *ſamolus valerandi*, called *anagallis aquatica rotundifolia*, or the round leaved water brook lime, by authors. *Tourn.* Inſt. p. 143.

SAMP, in our American colonies, a name given to a ſort of bread made of the maiz, or Indian corn.

They firſt water the corn for about half an hour, and then beat it in a mortar, or grind it in a hand mill; they then ſift out the flour, and winnow the huſks from it; they then mix this into a thin paſte with water, and bake it in flat loaves, which they call *ſamp* loaves, or *ſamp* bread.

Beſide this they have another diſh prepared of this corn, which they eſteem a great delicacy, and call by the name of *ſamp*, without the addition of loaf or bread. To make this, they only bruiſe or grind the corn to the ſize of rice, and then winnowing away the huſks, they boil it gently till it is thoroughly tender, and then add to it milk and butter, and ſugar: this is not only a very wholſome, but a very pleaſant diſh. It was the firſt diet of our planters when newly ſettled there, and is ſtill in uſe, as an innocent food in ſickneſs as well as health.

The Indians, who feed on this ſort of food, are found never to be ſubject to the ſtone, and to eſcape ſeveral other painful diſeaſes.

The Engliſh have found a way of making a very good ſort of beer of the grain of this Indian corn: they do this either by uſing the bread made of it, or elſe by malting it as we do our own corn. When they make the beer of the maiz bread, they break or cut it into lumps as big as a man's fiſt; they maſh theſe in the ſame manner that we do malt, and boil up the wort in the ſame manner, either with or without hops. Phil. Tranſ. Nº 142.

SAMPHORÆ, among the antients, were horſes marked with the letter Σ on their legs. *Pitiſc.* in voc.

SAMPSUCHUS, a word generally uſed as a name of the common ſweet marjoram. This is as old a cuſtom as Dioſcorides; for that author expreſsly ſays, that the plant *ſampſuchus* was called *amaracus* by the Cyzenians, and ſome others whom he names, and ſeems to make them proper ſynonyms of the ſame plant; yet afterwards mentioning the oils, called *oleum ſampſuchinum* and *oleum amaracinum*, he declares them to be different medicines.

This might ſeem to imply a falſe text, either by the error of the tranſcribers or printers, in one of the places, but thoſe who are verſed in the writings of Dioſcorides, will not infer ſo much; for there are too many inſtances of this ſort of contradiction in his works. It appears, however, from the moſt antient writers of all, that the *amaracus* and *ſampſuchus* were originally the names of different plants.

Meleager in his poem, where he compares the ſeveral poets of his own and former times to the flowers of various garden plants, compares one to the *amaracus*, and another to the *ſampſuchus*. Galen and Paulus Ægineta alſo make them different plants, and allot different chapters to the treating of them. This would never have been the caſe, had the general opinion of the world at that time made them one plant; and the teſtimony of Dioſcorides, that they were ſo, will weigh very little with thoſe who know how often that author, though excellent in his way, is guilty of inaccuracies of this kind.

Diocles, in Athenæus, indeed mentions *amaracus*, which ſome call *ſampſuchus*: but even allowing that ſome people did call the *amaracus* by this name, it does not follow but that this might be improperly done, and that the *ſampſuchus* might ſtill be the name of a different plant.

SAMYDA, in botany, the name of a genus of plants firſt deſcribed by Plumier, and called by him *guldonia*; the characters are theſe. The cup is a very large one-leaved perianthium

anthium, divided into five segments, which stand wide expanded, and remain when the flower is fallen, and are of an oval figure. The flower is of the shape of a truncated cone; it is of the length of the cup, and is dentated at the edge, and sulcated. There are no stamina, but the apices stand each at the summit of one of the jags of the flower, and are of a roundish figure. The germen of the pistil is of an oval figure; the style is of the length of the flower, and is of a pointed form; and the stigma is headed. The fruit is an oval berry with four deep furrows, divided into four cells, and containing a number of kidney-shaped seeds in an oval receptacle. Linnæus thinks this nearly related to the *melia*. *Plumier*, 24. *Linnæi* Gen. Plant. p. 520.

SANALIA, a name given by some authors to those tumors, commonly called *meliceres*.

SANAMUNDA, in botany, a name used by some authors for the sea heath spurge, or empetrum of the shops; a plant of the thymelæa kind.

In the materia medica, however, according to most catalogues, the *sanamunda* is appropriated to be the name of the heath spurge, another plant of the thymelæa kind, different from the sea sort. *Park.* Theatr. p. 203. *Dale's* Pharmac. p. 314.

SANATES, among the Romans, an appellation given to those people in the neighbourhood of Rome, who having revolted, soon submitted themselves again; on which account they had equal privileges with the other citizens, there being a law in the twelve tables ordaining *ut idem juris* sanatibus *quod fortibus sit*. *Pitisc.* in voc.

SANATODOS, in natural history, a name given by the people of Sicily to the spungy excrescence found on the stalk of the dog rose, and more usually called the *bedeguar*.

This they greatly esteem in all venomous bites, and use it in fine powder, both internally and externally, in many parts of that country. They use no other remedy for the bite of a viper: the wound is scarified, and some of the powder is sprinkled on, and large doses of it are also given internally in strong wine.

In the bite of a mad dog they apply it to the wound, softened into a sort of pultice with oil, or with strong wine; and they give it in repeated doses internally in broths, and other weak fluids. They give it also in continual fevers, and in many other cases, particularly in the colic. It is said, that a single dose of a dram of it, in red wine, takes off all the pain of the colic in an hour.

There seems a very old opinion on the side of this medicine, in the cure of a bite from a mad dog; for Pliny tells us, that the root of the wild rose, from the stalks of which this substance grows, was revealed in a dream for the curing this terrible disease. People, who have found out some one virtue in a plant, are generally ready to attribute a great many more to it; but though too much may be said in praise of the virtues of this substance, by the people of that part of the world, it is well worth trying whether it does not contain some of them, as it is a thing very common among us, and easily had in any quantities. *Boccone's* Museo de Piante.

SANCTORIAN *tables*, is used to signify such registers as exhibit the quantities of perspiration, its proportion to stool or urine, &c. We have such tables from the observations of Dr. Lining at Charles-Town, South-Carolina. See Philos. Trans. Nº 470, and 475.

SANCTUARIUM, in ecclesiastical writers, the same with *brandeum*. See BRANDEUM.

SANDS, *arenæ*, in natural history, a genus of fossils, the characters of which are; that they are found in minute concretions forming together a kind of powder, the genuine particles of which are all of a tendency to one determinate shape, and appear regular, though more or less compleat concretions; not to be dissolved or disunited by water, or formed into a coherent mass by means of it, but retaining their figure in it; transparent, vitrifiable by extreme heat, and not dissoluble in, nor effervescing with acids. *Hill's* Hist. of Foss. p. 544.

These are subject to be variously blended and intermixed either with homogene, or heterogene particles, particularly with flakes of talc; and according to these, and their different colours, are to be subdivided into several kinds.

White SANDS. Of such of these as are pure and free from heterogene particles, we have only six known species. 1. A fine shining kind, commonly used for strewing over writing, and common in many parts of the kingdom. 2. A large shining white *sand*, found in great plenty about Maidstone, and sent up to London for the making our common white flint glass. 3. A very fine white glittering *sand*, found on the shores of some rivers in Italy, and used there for the finest glass. 4. A brownish white fine, but dull looking *sand*, very common in France, and used there in glass-making for the green glass; but though common enough with us also, is so much inferior to the other kinds we have, that it is never used or regarded. 5. A yellowish white fine dull *sand*, common in the deserts of Africa, and not less so in Italy, America, and England, but made no use of. And 6. a reddish white one, common in Sussex, and in many other places.

Of the white *sands*, mixed with *sandy* particles of other colours, we have three species. 1. A large brownish white shining *sand*, found, so far as is yet known, only in one place, which is in the loam pits in Hedgerley near Windsor; and this is the very *sand*, of which with clay that loam is composed, and to which probably it owes its value. 2. A large yellowish white shining *sand*, which nearly resembles the former kind, and which might be of use to make an artificial loam, in the place of the natural one beforementioned, as also in the glass trade: this is found about Deptford, Highgate, Hampstead, &c. 3. A large coarse variegated *sand*, made up of white, black, reddish, and brown: this is very common in our gravel pits, and on the shores of the sea and rivers.

Of the white *sands*, containing heterogene particles, there are also three kinds. 1. A fine dull brownish white *sand*, with micæ, or small spangles of talc: this is common near the surface in most parts of England. 2. A fine dull greenish white *sand*, with micæ, common about Deptford, Woolwich, &c. And 3. a fine glittering greyish white *sand*, with micæ, found in great plenty on the shores of the islands of Scilly.

Red, or *reddish* SANDS. Of those which are pure there are five species. 1. A large shining red *sand*, found on the shores of the island of Santorini. 2. A large shining flesh coloured *sand*, common about Naples. 3. A coarse shining brownish red *sand*, common on the heaths of Sussex. 4. A fine brownish red shining *sand*, found near the surface on Hampstead heath. 5. A fine pale brownish red shining *sand*, frequent near the surface on the heaths of Sussex. *Hill's* Hist. of Fossils.

Of the impure reddish *sand* we know only one species, a pale red very fine one, with micæ: this is common in the deserts of Arabia, and not in any other place, so far as is yet known.

Yellow SANDS. These are a very numerous sort. Of those which are wholly pure we have thirteen known species. 1. A fine pale brownish yellow one, common on Hampstead heath. 2. A fine shining pale reddish yellow one, common about Highgate. 3. A very fine shining pale yellow one, common in the deserts of Arabia, and also found with us in Kent and Sussex. 4. A fine shining gold coloured *sand*, common on Hampstead heath. 5. A very coarse shining pale yellow one, frequent every where to the north of London. 6. A coarse dull whitish yellow one, common in Hyde-Park. 7. A large shining yellow one, found also in Hyde-Park. 8. A coarse very bright yellow one, found in Northamptonshire, and in some other counties. 9. A large dull yellow one, common on the shores of our rivers. 10. A fine dull deep yellow one, common in America, and in England. 11. A dusky yellow shining coarse one, found on Hampstead heath. 12. A coarse shining brownish yellow one, common among gravel about London.

Of those mixt with arenaceous particles of other colours, we have six known species. 1. A fine greenish yellow pale and dull one, found on Hampstead heath. 2. A fine greenish and reddish yellow pale dull one, found in Sussex. 3. A coarse blackish yellow shining one, common about Tyburn and elsewhere. 4. A fine blackish yellow shining one, common about London. 5. A large shining blackish and pale yellow one, found about Hampstead. 6. A fine deep yellowish brown shining one, found in Gloucestershire, and some other counties.

Of the yellow *sands* which contain heterogene particles, not arenaceous, we have nine species. 1. A brownish yellow fine one, with micæ, found about Hampstead. 2. A fine pale reddish yellow one, with small spangles, common in America, and found with us in Sussex and elsewhere. 3. A coarse straw coloured *sand*, with micæ, found in Sussex, and about London. 4. A coarse sulphur coloured *sand*, with micæ. This is a more scarce species. 5. A large shining yellow *sand*, with micæ, found on Hampstead heath. 6. A fine dull deep yellow one, with micæ, common in most parts of the kingdom. 7. A large deep yellow *sand*, with micæ, found in Northamptonshire, and some other counties. 8. A coarse saffron coloured *sand*, with micæ, common in Germany, and found also in Sussex. 9. A deep brownish yellow fine *sand*, with micæ, found about Highgate.

Brown SANDS. Of those of this colour which are pure, we have only three known species. 1. A fine brown *sand*, frequent about Woolwich. 2. A coarse shining pale brown one, found on the shores of the Thames. And 3. a coarse purplish brown shining one, common about Bristol.

Of those containing heterogene particles, we have only two species. 1. A dull brown coarse *sand*; this has among it some fragments of spar. It is found on the shores of rivers. 2. A coarse shining pale brown one, common among gravel on the beds of rivers.

Black SANDS. Of these we have only two species. 1. A fine shining greyish black one, found in Italy, but not with us. 2. A fine shining reddish black one, which seems peculiar to America.

Green SANDS. Of these we yet know only one species, which is a coarse variegated dusky green one, common in Virginia,

nia, but not known elsewhere. *Hill's* Hist. of Foss. p. 568. It is remarkable that *sand*, though it appear a very hard, dense, and indissoluble body, yet is contained invisibly in the brine, or salt water of our salt springs; and even on the shooting of the salt, after evaporation, there still remain the particles of it in the clear pellucid salt; and this, though wholly soluble in water, yet when a brine, made by such a solution, is boiled, deposits as much of the *sand* as the common brine of the pits, or sea water.

Dr. Plot, who was very curious to know the true history of this singular effect, procured experiments to be made in the following manner. Eight folds of fine Holland, and as many of much finer cambrick, were put together, and a quantity of the brine of the Staffordshire salt pits being strained through this, there was nothing separated from it but a small quantity of black dust, which seemed to have fallen in by accident, and which was not at all like *sand*; yet on evaporating this brine, it was found to contain no less than one fourth part as much *sand* as salt. The quantity of brine yielding a bushel of salt, yielding also a peck of *sand*.

Some have supposed from these, and the like observations, that the *sand* was generated during the time of the boiling of the liquor, but the more careful examiners think otherwise; it appearing to them, that the particles of this *sand* may be seen in the brine, by the help of a microscope, before the boiling, in form of rectangular oblong plates, some nearly square; these were so small, as readily to pass the strainer with the water; and appearing as numerous in it after, as before the straining, shew that they are no more to be kept, but by such means, than the salt.

The pores of the finest strainers, examined by the microscope, appear twenty times bigger than these plates, or particles of the *sand*, and therefore it is not to be wondered at, that they let them through. There requires, therefore, no more to the formation of the *sand*, than the coalescing of several of these particles into one larger granule, and so on; and this is very likely to be done by means of the evaporation of a part of the fluid which kept them separate, and of the motion given to them in boiling, which naturally and necessarily brought them into the spheres of their own mutual attractions, at a time when their attraction with the fluid they swam in, was also much diminished with its quantity. This attraction seems even evidently to increase between the particles, as the water becomes evaporated, and when finally the salt is drawn from it, and it is examined as it drops from the baskets, in which the salt is put to drain; it is seen to contain more numerous particles of this sandy matter than before; and these are found to coalesce into yet larger concretions, by degrees, as the remainder of the fluid evaporates from them on the glass.

The particles of this stony matter, when once thus united, are no more to be separated by water, nor is the matter any longer soluble in that fluid. The common spar found in form of stalactites and incrustations on the roofs, walls, and floors of old caverns, shews that it was once dissolved in water, and by that means brought to those places, and made into those forms; and it should seem, that this *sand*, as it is called, was only this sort of spar, which is contained more or less in all water; and which, on the evaporating of that water and separation of the salt, which might help in making the water a menstruum proper for the retaining it, shoots out into its own natural concretions; for the figure of these thin plates is the true and natural thin parallellopiped or rhomboidal figure of the smaller concretions of that matter, and even of those pieces into which it falls on breaking. Phil. Transf. N° 145.

Sand seems to have been the first substance added to proper salts for the making of glass. Josephus, Tacitus, Strabo, Pliny, Agricola, &c. all mention this, and tell us of the stores, from which the *sand* for this use was brought, being inexhaustible.

Later ages have found that stones which have crystal for their basis make a finer glass than *sand*, of this kind are flints, &c. but these all are so expensive in their preparation, that *sand* is still used in much greater abundance than any other ingredient. All the preparation it requires, is, that it be well washed before it is used; which much of what is used is found ready to their hands, being brought from the shores and beds of rivers.

Our glass-houses, in London, use for their white glass the common white *sand* used in writing, and have it from Maidstone in Kent in vast quantities. For their green glass they use a common coarse and greenish looking *sand*, of which there are vast strata at Woolwich. *Merret's* Notes on Neri, p. 260.

Common *sand* is a very good addition by way of manure to all sorts of clay lands, it warms them, and makes them more open and loose. The best *sand* for the farmers use is that which is washed by rains from roads, or hills, or that which is taken from the beds of rivers; the common *sand* that is dug in pits never answers nearly so well. *Sand* mixed with dung is much better than laid on alone: and a very fine manure is made by covering the bottom of sheep folds with several loads of *sand* every week, which are to be taken away, and laid on cold stiff lands, impregnated as they are with the dung and the urine of the sheep.

Beside clay land there is another sort of ground very improveable by *sand*; this is that sort of black foggy land on which bushes and sedge grow naturally, and which they cut into turff, in some places. Six hundred load of *sand* being laid upon an acre of this land, according to the Cheshire measure, which is near double the statute acre, meliorate it so much, that without plowing, it will yield good crops of oats or tares, though before it would have produced scarce any thing. If after this crop is taken off, the land be well dunged, and laid down for grass, it will yield a large crop of sweet hay.

Once sanding this land will improve it for a vast number of years, and it will yield two crops of hay in the year, if there be weather to make it in. Some land in Cheshire has been, by this means, rendered of twelve times its former value to the owner. The bogs of Ireland, when drained, have been rendered very fruitful land, by mixing *sand* in this manner among the earth, of which they consist. Add to this, that in all these boggy lands, the burning them, or firing their own turff upon them, is also a great advantage. The common peat, or turff ashes, mixed with the *sand* for these purposes, add greatly to its virtue.

Sea *sand*, which is thrown up in creeks and other places, is by much the richest of all *sand* for manuring the earth, partly its saltness, and partly the fat and unctuous filth that is mixed among it give it this great virtue. In the western parts of England, that lie upon the sea coasts, they make very great advantages of it. The fragments of sea shells also, which are always in great abundance in this *sand*, add to its virtues; and it is always the more esteemed by the farmers, the more of these fragments there are among it.

The sea *sand* used as manure in different parts of the kingdom is of three kinds: that about Plymouth, and on other of the southern coasts, is of a blue grey colour like ashes, which is probably owing to the shells of muscles, and other fish of that or the like colour, being broken and mixed among it in great quantity. Westward, near the land's end, the sea *sand* is very white, and about the isles of Scilly it is very glistering, with small particles of talc; on the coasts of the north sea the *sand* is yellowish, brown, or reddish, and contains so great a quantity of fragments of cockle shells, that it seems to be chiefly composed of them. That sea *sand* is accounted best, which is of a reddish colour: the next in value to this is the bluish, and the white is the worst of all.

Sea *sand* is best when taken up from under the water, or from *sand* banks, which are covered by every tide.

The small grained *sand* is most sudden in its operation, and is therefore best for the tenant who is only to take three or four crops; but the coarse or large grained *sand* is much better for the landlord, as the good it does lasts many years.

Where the *sand* is dredged out of the sea, it is usually twice as dear as where it is taken from the *sand* banks.

When the land has been well manured with the large *sand*, they take four crops of corn from it, and then lay it down for pasture for six or seven years before they plow it again. The grass is so good, that they commonly mow it for hay the first year; it always abounds very much with the white flowered clover. If the grass grows but short, it is the farmer's interest to feed his cattle upon it, and it will turn to as good account this way, being very sweet and rich, and making the cattle fat, and the cows yield a very large quantity of milk. *Mortimer's* Husbandry.

Indian Sand. The substance, commonly called *Indian sand*, is famous for answering to the magnet. It is brought into several parts of Europe, and is said to be gathered on the sea shore in Persia. After it is gathered, it is boiled in water to wash away the sea salt and other impurities it may contain. After this operation, it is dried and sent abroad in form of a black powder, consisting of grains of different sizes. Some of these grains are very rough in every part of their surface, and others have one side only rough, the others perfectly smooth and glossy. Their figure is very irregular, and resembles that of the grains of common *sand* only; the grains of this *Indian sand* are usually smaller than those of our common *sands*.

These little lumps have neither taste nor smell, and are so friable, that they are easily reduced to an impalpable powder by rubbing. Some of the particles are strongly attracted by the loadstone, and others are so inactive as to be scarce at all affected by it. Those particles, which are of the deepest dusky black, are most of all affected by the loadstone; those which are not affected by it, seem rather of the colour of lead, of a bluish black and shining; these are in the greatest quantity, and the others are selected from among these by the loadstone. Phil. Transf. N° 432. p. 298.

Muschenbroek considering that some of the particles of this *sand* had so strong a magnetic virtue, and others scarce any at all, was tempted to try whether it might not be possible to increase the like virtue in these last, and after some trials he found a way to succeed in this attempt; suspecting, that there

there might be too great a quantity of fulphur adhering to the *fand*, to fuffer it to be turned into any metalline regulus by a long continuance in an open fire; he mixed it with half its quantity of pot-afh, and toafted it in an open crucible about two hours: after this the falt being wafhed away with common water the *fand* was found to be much blacker than before, and about one fourth of it was now endued with a very powerful magnetic force.

The falt has a great fhare in making this *fand* magnetic after burning; for a burning of it, without that admixture, is found to give it, indeed, fome power of this kind, but it is very little.

There is another matter, however, which being mixed with this fand, contributes yet greatly more to its virtue, this is black foap. This *fand* being mixed with an equal quantity of black foap is to be put into a crucible, and placed in a gentle fire, where the foap will fwell and bubble up; as foon as this is over, and the moifture all evaporated, the fire is to be increafed, and the matter kept red hot, about half an hour, or a little longer than that; then the crucible being taken out, and cooled, the remainder is to be wafhed, and this will be then a black powder; every grain of which is magnetical, and that very beautifully. If the operation be ever fo many times repeated on the fame *fand*, the power remains the fame in it, neither being increafed nor leffened by all the work.

A mixture of one third of this *fand*, one third of black foap, and one third of falt of tartar, treated in the fame manner as the former, feems to increafe the virtue of magnetifm yet farther in the *fand*, than when treated with the foap alone; beef fuet mixed with the *fand* gives it much of the magnetic virtue, after melting and burning it away on the fire; and common pitch treated in the fame manner with it, yet greatly increafes it. If it be too long kept over the fire, with any of thefe mixtures, the virtue decreafes, and if not long enough, it does not arife to its utmoft height; fo that experiments only can fettle the true degree of heat, neceffary to its greateft perfection.

The greateft power that can be given to this *fand*, in this quality of magnetifm, is, however, to be given in the following manner. Mix together equal parts of the *fand*, and of rofin, pitch, frankincenfe, and rape oil, put this into a crucible, and lute it well in all parts, then place it for an hour in a reverberatory furnace: when this is cooled, there will be found black grains of the *fand*, between black coals of the oily matter, which, when feparated, will leap up to the magnet, when held at fome diftance over them; and fhew, in all refpects, the ftrongeft magnetic virtue, that we know communicable to this fubftance.

It might appear, from this experiment, that the *fand* grew more fenfible of the magnet, as its particles more approached to the nature of fteel; but on making the trial by calcining the *fand* with the ingredients ufed to turn iron into fteel, fuch as chimney foot, fea falt, powdered charcoal and afhes, it acquired fome magnetic virtue indeed, but not nearly fo great as that given it by the laft procefs, or by the fimply mixing it with bluifh foap before the calcination.

After thefe experiments, the queftion naturally occurs, of what can this *fand* be. It has been fuppofed by fome, to be the granulæ or fragments of load-ftones, or the feparated particles, which when concreted into a mafs, afford the common magnet; but this can by no means be the cafe, fince common load-ftones lofe of their force, by being calcined with the very ingredients which render this magnetic; and indeed the phænomena it affords on experiments are fo very fingular, that it is not eafy to determine any thing about it.

There are feveral parts of the world which afford this *fand*, but with fome difference in the figure of its grains, and their magnetic virtue. Befide Perfia it is found on the fhores of Virginia; another fort of it is found about Italy, and very common at Leghorn; this is very magnetic. There are two forts of it found in the river Eber in Haffia, of which one is like the Italian, but the other confifts of large grains, almoft as big as hempfeed, but having very little virtue. A very ftrong fort is found in Dalmatia, near old Ragufa; and probably future enquiries will fhew, that there are yet many more kinds of it differing in ftrength and fize. Phil. Tranf. Nº 432. p. 301.

Sand *bags*, in the military art, are bags of earth or *fand*, containing about a cubical foot; they are ufed for raifing parapets in hafte, or to repair what is beaten down.

They are alfo of ufe when the ground is rocky, and affords no earth to carry on their approaches, becaufe they can eafily be brought from far off, and removed at will.

The fmaller *fand-bags* hold about half a cubical foot of earth, and ferve to be placed upon the fuperior talus of the parapet, to cover thofe that are behind, who fire through the embraffures, or intervals, which are left betwixt them.

Sand *flood*, a term ufed by the people of Suffolk, and fome other parts of England, to exprefs a mifchief to which they are fubject, by having their lands covered with vaft quantities of *fand*, rolling in upon them like a deluge of water.

Mr. Wright, a fufferer by one of thefe deluges, gives a very good account of them in the Philofophical Tranfactions. In the neighbourhood of the plains, fubject to this mifchief, there are always hills which are made up of *fand*, and only covered with a thin turf. The plains themfelves, which are inevitably ruined by the deluge of this dry fort, are alfo fandy; having only the fame fort of thin turf on them, though capable of producing very good crops, and ftanding all common accidents.

Violent winds break through the turf that covers thefe hills, and then the *fand* lying loofe and naked, is foon carried down upon the plains, where it covers and buries the grafs, and in a very little time eats through the light turf, and mixing itfelf with the *fand* underneath, becomes one bed of this dry matter never to be covered with a turf again. A large body of *fand* being thus got together, nothing ftops its progrefs; but it at every ftorm rolls over more and more ground, fo that in a few years it extends itfelf a vaft way; efpecially where the ground, over which it paffes, is of the fame fandy nature, and only covered with a thin turf.

In fome parts of Suffolk the ground encourages this change fo greatly, that a bed of *fand* broke loofe from a neighbouring hill, and covering only a few acres, perhaps eight or ten, will, before it has travelled four miles forward, which it does in a fmall courfe of years, deluge a thoufand acres. It travels down hill fafter than any way elfe, but will not be ftopped by afcent, but will move up the fteepeft hill, only that it requires more time. The making of fences, in the common way, to keep it out is vain. It runs through the hedges, and flies over the tops of the banks; and when it reaches a village, in its courfe, will bury the cottages, unlefs preferved at more charge than they are worth. It will in a very little time beat up to the eaves of a houfe, of the low kind, that are ufually built in country villages, and has often weight enough to break down walls in its paffage.

The beft way of ftopping its progrefs is by hedges of furze, planted one over another as they become levelled; thefe, if well kept up, will, by degrees, ftop or divert the progrefs; and fome who have tried this, with refolution, after they have had the *fand* raifed twenty feet high, have found it ftop its increafe; and then having manured this adventitious foil with dung, found it as good ground as that which made the furface before.

About Thetford the villages were wholly deftroyed by this about ninety years ago; and the branch of the river Oufe, called then Thetford river, fo blocked up by it, that very fmall veffels only could go up it, where very large ones ufed before. The river has been of great fervice in ftopping its progrefs into Norfolk, where otherwife its courfe would have carried it, and its vaft fpreading fideways in proportion of its going forward, would have made it bury vaft quantities of land in a very few years.

The moft probable conjecture, as to the caufe of this ftrange fort of deluge in thefe parts of England, is, that this portion of the county of Suffolk lies eaft north eaft of a part of the great level of the fens, and is by this expofed to very impetuous winds, which acquire more than ordinary force, by their paffing through fo large a tract of country uninterrupted; the ftorms feem to be one great caufe of the mifchief, and the fandy nature of the foil the other. There are old ftories in the country, of fuits at law commenced among the farmers, for grounds blown out of the owner's poffeffion; but the people who gain this fort of wandering land are the greateft fufferers. A little *fand* fprinkled by the winds over a tract of land, where there is a bed of *fand* under the turf, foon eats through that obftacle; and what was at firft only a thin coat of *fand*, becomes then a deep plain of it, capable of being blown away to the depth of eight, ten, twenty, or more feet, and is carried over every thing in its progrefs before the winds, when once taken up by them. Phil. Tranf. Nº 37.

Sand-*gavel*, a payment due to the lord of the manor of Rodley, in the county of Gloucefter, for liberty granted to the tenant to dig *fand*, for their common ufe. *Blount*.

Sand-*lands*, a term ufed by our farmers to exprefs fuch grounds, as confift wholly of a pure fheer *fand*.

This is of different colours, as white, blackifh, reddifh, or yellowifh, and is very different in its nature, and in the fize of its particles, fome being harfher and fome milder, and fome very light, feeming only to be mere duft. The grey, black, and afh-coloured *fand*-lands are the worft of all, and generally are found on heaths and commons. Gravelly lands approach much to the nature of thefe, and thofe which confift of largeft ftones, and are mixed with the harfheft *fands*, are of all the moft barren.

The propereft plants for arable land, of this kind, are white oats, rye, black wheat, and turneps. The natural produce, in weeds, is quick grafs, forrel, broom, furze, fern, and heath.

The beft manure for them is either marl, or fuch clay as will break with the frofts. Cow dung is alfo a good manure for thefe lands, and many ufe with fuccefs chalk, mud, and the half rotten ftraw from dunghils.

When

When the farmer has a mind to raiſe corn on theſe lands, he muſt order them, as the clays; (ſee CLAY-*lands*) but where they are over-run with broom, furzes, and ſuch ſort of weeds, marl is to be laid on in great quantities. This is the practice in Staffordſhire, and by it they rid themſelves of theſe troubleſome weeds, and procure good crops of corn, though at ſome expence.

The firſt ſowing of this land is with black wheat, and for this they make three fallowings in winter, and ſtir them in the May following; at this time they ſow them, allowing one buſhel of ſeed to an acre, which generally yields them ſixty again. Then once plowing theſe lands, after this crop is off, they are fit to ſow rye on.

In Oxfordſhire they ſeldom give theſe lands more than two fallowings for wheat, except they are very much over-run with weeds; and they eſteem the white and lammas wheat the moſt agreeable for this ſort of land, and then after a fallow rathripe barley. They afterwards generally fallow them every other year, and reckon them unfit for beans and peas, though they ſometimes ſow them with winter vetches. If they ſow peas on them, they eſteem the rathripe kinds the beſt.

In Herefordſhire they are much ſubject to moſs growing upon their *ſandy lands*, and they make a great improvement by burning it on the ground, and mixing the aſhes with lime, which they then plow in.

They generally ſow them with rye after this manure, and that yields a very great increaſe upon them, and brings on a very good kind of graſs, if they are laid down after a crop or two. *Mortimer*'s Huſbandry, p. 70.

SANDAL-*bricks*. See the article BRICK.

SANDALIGERULI, among the antients, ſervants whoſe buſineſs it was to carry their maſter's or miſtreſs's *ſandals*. *Pitiſc.* in voc. See SANDAL, *Cycl.*

SANDAPELONES, among the Romans, a kind of porters who were employed in carrying the bier called *ſandapila*. *Pitiſc.* in voc. See SANDAPILA.

SANDAPILA, among the Romans, a ſort of bier uſed for carrying out the bodies of people of low circumſtances.

It was not a bed, but a kind of wooden cheſt, made of a few boards nailed together, and was uſually burnt along with the body. *Pitiſc.* in voc.

SANDARACH, (*Cycl.*) in the works of ſome of the antients, a name by which the yellow matter collected on the legs of bees is called; others of them called it *erithace* and ſome *ambroſia*.

We uſually eſteem this to be wax; but the experiments of Reaumur, and others, evidently prove, that it is not real wax; though it contains the matter of which wax is to be made: it is only the farina of flowers, collected into lumps, and probably ſerves the bees as food; and after it has afforded them nouriſhment, ſuffers ſome change in their bowels, by which it is converted into the ſubſtance we call wax. *Reaumur*'s Hiſt. Inſ. V. 10. p. 510. See PAIN *d'abeile.*

Gum SANDARACH is eſteemed good in diarrhœas and hæmorrhages, its doſe being from ten grains to half a drachm. It is alſo ſometimes preſcribed in gonorrhœas and the fluor albus. See SANDARUS, infra.

SANDARESUS, in natural hiſtory, a gem, the chief property of which, according to Pliny, is its being pellucid, and containing in its ſubſtance a kind of gold coloured globules; which are likewiſe tranſparent, when ſeen betwixt one and the fire. *Hofm.* Lex. univ. in voc.

SANDARUS, in the materia medica, the original name of the gum, which later ages have, by corruption of the name, called *ſandarax* or *ſandaracha*. The latter name is peculiarly improper, as it confounds this innocent gum with a poiſonous mineral of the arſenic or orpiment kind.

The Arabians are not eaſily to be underſtood in what they ſay of this gum. Some deſcribe it as a diſtinct gum from all others, and ſay that it reſembled amber in its colour and properties; this ſeems to expreſs properly what we at this time call *ſandaracha*, which has much of the appearance of yellow reſin, and therefore cannot be wholly unlike amber; but, as this gum was uſed in varniſh, and ſeveral other gums were alſo uſed for the ſame purpoſe, theſe writers, according to their uſual cuſtom of attributing the ſame name to different things, which had the ſame properties, have ſometimes called the *cancamum* by this name, and ſometimes amber. Gum lacca has often been called alſo by this name by theſe authors; and the context only can clear up what is meant, when either the word *ſandarus* or *cancamum*, or vernix is uſed.

SANDASTER, in natural hiſtory, a kind of gem mentioned by Pliny, with gold coloured globules in it that ſhone like ſtars, and were in number and diſpoſition not unlike the ſeven ſtars. *Hofm.* Lex. in voc.

SANDIVER (*Cycl.*)—It is reported, by many authors of great credit, that this ſalt, in its genuine form, and no way differing from ſuch as is ſeparated from glaſs, is thrown out in great abundance in the eruptions of the burning mountains, and lies about in lumps of a ſpungy texture and great ſize, or in ſmaller ſolid ones among the ſciarri and aſhes thrown out at thoſe times. The more firm and ſolid pieces are the moſt pure, and are generally of a fine white; the others not unfrequently are tinged bluiſh or yellow, and have ſometimes ſome of the melted matter of the ſciarri blended among the maſs, and filling up ſome of the cavities. In the catalogue of the ſpecimens of ſubſtances thrown out of Mount Ætna in one of its eruptions, and ſent as a preſent to the Royal Society, we find mention of ſeveral pieces of *ſandiver*, but without any particular deſcription. Phil. Tranſ. N° 53.

SANDYX (*Cycl.*)—Though the generality of authors have taken this to be only a name for the fine red colour, ſome have plainly uſed it for a bluiſh green.

Strabo tells us, that the colours uſed by painters, in his time, and called *armenium pictorium*, was of a bluiſh green colour, and that it was called *ſandycis metallum* by ſome. Thus the word *zarnich* was made to expreſs the ſame two things with the addition of the yellow orpiment; and Aviſenna deſcribes them all together, telling us, that *zarnich* is yellow, red, or green. The two firſt of theſe colours are natural to zarnich, as the name of orpiment; and there is, indeed, a greeniſh zarnich now alſo known in the world, but that was unknown in his times; and, we find, that he meant the *lapis armenus* by the *green zarnich*.

SANE *memory*, i. e. Perfect and ſound memory to do any lawful act.

SANGUINALIS *lapis*, in natural hiſtory, the name of a ſtone, deſcribed by Monardes, and other authors, and celebrated for its great virtues againſt hæmorrhages.

It is of the Jaſper kind, and is properly to be called an accidental heliotrope, being of a duſky green, ſpotted and veined with red; and differing in nothing from our common heliotropes, which are brought from the Eaſt-Indies, but in that it is leſs tranſparent and coarſer. See the article HELIOTROPE.

SANGUINARIA, *bloodwort*, a name given by many botanical authors to the *lapathum ſanguineum*, or bloody dock, from the red veins in its leaves; and by ſome to the *cornu cervinum*, or buckſhorn plantain, from its ſuppoſed virtues. *Ger.* Emac. Ind. 2.

SANGUINARIA, in botany, the name of a genus of plants, the characters of which are theſe. The ſpatha is compoſed of two leaves, and is oval and concave, and ſhorter than the flower. The flower conſiſts of eight oblong and obtuſe petals; they ſtand very wide expanded, and the inner ones are narrower than the outer. The ſtamina are numerous ſimple filaments, ſhorter than the flower. The antheræ are ſimple. The germen of the piſtil is oblong and compreſſed. There is no ſtyle. The ſtigma is thick furrowed, with ſtriæ all along, and equals the ſtamina in height. The fruit is an oblong capſule, compoſed of two valves, and containing many round ſeeds. *Linnæi* Gen. Plant. p. 227. *Dillen*, Hort. Eltham, p. 252.

SANGUINEA, a name given by ſome of the chemiſts to nitre. See NITRE.

SANGUINEOUS *fevers*, a term uſed by the medical writers to expreſs a kind of fever, in which there is always a plethora, or fullneſs of blood, which nature is attempting to leſſen by means of this accelerated motion of it, either by forming ſome hæmorrhage, or by throwing a part of it off in form of ſweat. It is very obvious to reaſon, therefore, that bleeding is the firſt thing neceſſary in theſe fevers. The continent fevers, ſuch as the ephemera and ſynocha, are of this kind. *Junker*'s Conſp. Med. p. 252.

SANGUINEROLA, in ichthyology, a name given by the Italians to the *phoxinus*, or minow. Artedi makes this a ſpecies of cyprinus.

It has the Italian name from the blood red colour which diſplays itſelf under its belly. *Willughby*, Hiſt. Piſc. p. 268. See PHOXINUS.

SANGUINUS, in botany, a name given by ſome of the antients to the birch tree, from the deep reddiſh black colour of its twigs. Pliny calls it *ſanguineus frutex*, and not underſtanding that it was the ſame with the birch, mentions the name of that tree immediately after it, as if different from it. The Italians ſtill call the birch *ſanguino*; and ſome authors, from the redneſs of the twigs of ſome ſpecies of the alaternus, have called that ſhrub the *ſanguinus albus*. Some have ſuppoſed that this name was uſed to expreſs the birch tree alſo, but erroneouſly; for though the bark of the body of that tree is ſometimes white, there was no reaſon for adding that epithet to the word *ſanguinus*, which not being uſed for any other tree, could need no diſtinction. The Romans, and many other nations, uſed this tree as we do, for the puniſhment of children's faults; and it is poſſible that the name *ſanguinus* might be given it on this occaſion. *Pliny*, lib. 16. cap. 36.

SANGUIPURGIUM, a name given by ſome authors to a ſlight ſpecies of fever which was judged ſalutary, and only ſerving to purge and cleanſe the blood.

SANGUIS *draconis herba*, in botany, a name by which ſome authors call the *lapathum ſanguineum*, or bloody dock. *J. Bauhin*, Vol. 2. p. 988.

SANGUISORBA, in the Linnæan ſyſtem of botany, the name of

of a diftinct genus of plants, the characters of which are thefe. The cup is a perianthium, compofed of two very fhort leaves, placed oppofite one to another, and falling with the flower. The flower is a fingle petal, divided into four oval obtufely pointed fegments, which cohere only at their lower extremities. The ftamina are four filaments, broad in the upper part, and of the fame length with the flower. The antheræ are fmall and roundifh. The germen of the piftil is fquare, and fituated between the cup and the flower. The ftyle is flender, and extremely fhort; and the ftigma obtufe. The fruit is a capfule containing two cells, filled with very fmall feeds. *Linnæi* Gen. Plant. p. 46.

SANGUISUGA, in zoology, a name by which fome authors exprefs the *hirudo*, or leech. *Charlt.* Inf. p. 62. See the article HIRUDO.

SANGUISUGUM, a name given by fome barbarous authors to a diforder of the heart, fuppofed to arife from its retaining an abundant quantity of blood.

SANICULA, *fanicle*, in botany, the name of a genus of the umbelliferous plants, the characters of which are thefe. The flower is compofed of feveral petals, which are difpofed in a circular form, and have their points bending inwards. Thefe ftand upon a cup, which finally becomes a fruit compofed of two echinated feeds, which are gibbofe on one fide, and flat on the other. Many of the flowers of the plants of this genus are barren.

The fpecies of *fanicle*, enumerated by Mr. Tournefort, are thefe. 1. The common wood *fanicle*; and 2. the Canada *fanicle*, with very large and jagged leaves. *Tourn.* Inft. p. 326.

The medical writers all agree in celebrating this plant, as one of the greateft vulneraries we have of our own growth. They recommend it for the healing frefh wounds and erofions; and many go fo far, as to talk of fiftulas having been cured, by injecting a decoction of it: but the modern practice of furgery has fallen upon very different methods of practice, in thefe cafes, from their predeceffors, and in confequence of that, the whole tribe of vulnerary herbs are difregarded.

SANIDIUM, in natural hiftory, the name of a genus of foffils, of the clafs of the felenitæ, but neither of the rhomboidal nor columnar kinds, nor any other way diftinguifhable by its external figure, being made up of feveral plain flat plates.

The word is derived from the Greek, Σανίδιον, tabella, a flat thin plate or table, and expreffes a body made up only of fuch plates. And the felenitæ of this genus are of no determinate form, nor confift of any regular number of planes or angles, but are merely flat, broad, and thin plates or tables, compofed of other yet thinner plates, like the talcs, but diftinguifhed from thofe bodies by this, that thefe plates are made up of arrangements of flender fibres, difpofed obliquely, but in uninterrupted lines acrofs the body.

The felenitæ having been always efteemed (when meant of this clafs of bodies, for fome have applied the word to certain fpars and other fubftances) regularly figured foffils, this genus has been overlooked by authors, and the fpecimens of it which occurred, looked on as bodies of a different clafs, as fpars or talcs. Their not fermenting with acids, however, determines them not to be fpars; and their obliquely ftriated ftructure, their want of elafticity, and their readily calcining in the fire, diftinguifh them from the talcs, and fhew them to be true and genuine felenitæ. *Hill's* Hift. of Foff. p. 122.

Of this genus there are only two known fpecies, the one colourlefs and pellucid, the other whitifh and opake. The firft is found pretty frequently about Oxford, as alfo in Northamptonfhire, Yorkfhire, and other counties; the other is very common in all parts of Germany, and is found alfo in Leicefterfhire, and fome other parts of England, but with us it is not common. *Hill's* Hift. of Foff. p. 144, 145.

SANIS, Σανίς, among the Greeks, a kind of punifhment, inflicted by binding the malefactor faft to a piece of wood. *Potter*, Archæol. Græc. Tom. I. p. 131.

SANKIRA, in botany, a name given by fome authors to the plant, of which the China root, ufed in medicine, is the root. *Kæmp.* Amœn. Exot. p. 781.

SANS *pareille*, in conchyliology, the name of a peculiar fpecies of buccinum, which has its mouth opening a contrary way to that of all other buccina. This is a fingle fpecies among the recent buccina, but we find more than one kind with this peculiarity among the foffile fhells, and that in great abundance in many places in England.

SANTALUM, (*Cycl.*) in botany, the name of a genus of plants, the characters of which are thefe. The perianthium is a narrow rim, ftanding on the germen of the piftil, and rightly indented into four fegments. The flower is monopetalous, and of the campanulated kind; its edge is divided into five acute fegments. The ftamina are eight filaments; they ftand on the upper part of the tube of the flower, and are alternately one fhorter than another. The antheræ are fimple. The germen of the piftil is turbinated. The ftyle is of the length of the ftamina; and the ftigma is fimple. The fruit is a berry. *Linnæi* Gen. Pl. p. 164.

SANTEO, in botany, a name given by the people of Guinea to an herb, which they efteem remarkably good in all difeafes of the eyes, the herb being boiled in water, and the eyes washed with it. The leaves of this grow in pairs, oppofite one to another, and have no footftalks. The joints, or fettings on of the leaves, are blackifh, and they are of the fize and fhape of thofe of the laurel. Philofoph. Tranfact. N° 202.

SANTOLINA, *female fouthernwood*, in botany, the name of a genus of plants, the characters of which are thefe. The flower is of the flofculous kind, and is of a globofe fhape. The feveral fmall flofcules, it is compofed of, are divided each into feveral fegments at the end, and are placed upon the embryos, with imbricated leaves between them, and the whole contained in a fcaly cup of a femiorbicular figure. The embryos ripen into feeds, which have no down, and the flowers are larger than thofe of the wormwood, or abrotanum.

The fpecies of *fantolina*, enumerated by Mr. Tournefort, are thefe. 1. The common *fantolina* with cylindric vermiculated leaves. 2. The *fantolina* with hairy woolly leaves, and with large flowers. 3. The *fantolina* with heath, or favinlike leaves. 4. The cyprefs leaved *fantolina*. 5. The creeping hoary *fantolina*. 6. The *fantolina* with lefs hoary leaves. 7. The *fantolina* with dufky green leaves, and fulphur coloured flowers. 8. The *fantolina* with dufky green leaves, and gold yellow flowers. 9. The great rofemary leaved *fantolina*. 10. The leffer rofemary leaved *fantolina*. 11. The corymbiferous African *fantolina* with a large coronopus leaf. 12. The corymbiferous African *fantolina* with a fmaller coronopus leaf. 13. The Spanifh camomile leaved *fantolina*. And 14. the Cretic *fantolina* with vermiculated leaves. *Tourn.* Inft. p. 460.

Santolina has the fame virtues afcribed to it with the *male fouthernwood*. See SOUTHERNWOOD.

It is alfo particularly recommended in uterine complaints. It is ufed to deftroy worms; and the powder of the dried leaves, half a drachm for the dofe, and to be continued for a confiderable time, is efteemed good in the fluor albus; alfo in pleurifies and peripneumonies.

SANTONICUM *femen*, in the materia medica. See the article CHOUAN.

SANTSI, in botany, a name given by the Chinefe to a plant, famous among them for its medicinal virtues.

It is defcribed by the writers, who have been on the fpot, in fo remarkable a manner, that it cannot eafily be miftaken, provided their defcriptions are juft. They tell us that it grows wild on the mountains in fome of the provinces of China, and that each root of it ufually fends up eight ftalks, the middle one greatly higher than the reft.

They have no branches, and have each only three leaves at the top, and the middle ftalk bears clufters of flowers. The root they fay is four inches thick, and pufhes out feveral fide branches, of the thicknefs of a finger. The bark of thefe roots is rough and brown, and their internal part foft and yellow.

The fmall roots only are ufed in medicine, the great ones being feldom found. The plant flowers in the month of July, and the fpring feafon is accounted the beft for taking up the roots.

The way of multiplying the plant is to cut the great root into flices tranfverfely, and plant thefe an inch deep in a good foil; they will foon fhoot up the natural number of branches, and in three years the plant will grow to its utmoft perfection.

The great ufe of the plant is in hæmorrhages, in which cafe it is faid to be almoft infallible. Obferv. fur les Cout. de l'Afie.

SAP *Cycl.*—*Courfe of the* SAP, a term ufed by gardners and nurfery men to exprefs the current of the *fap* in trees.

This has been generally fuppofed to run in an equable and even manner; but Mr. Fairchild has fhewn, that it has an irregular, and even contrary motion to its firft courfe.

This is a difcovery of more real ufe in gardening, than might at firft thought be imagined; fince this accurate experimenter obferves, that by means of it he could render barren trees fruitful, and decaying trees healthful, and render the fyftem of gardening much better in itfelf, and more ufeful to the public.

The laureola grafted on the mezereon, and the evergreen oak of Virginia upon the common Englifh oak; both thefe hold their leaves all the winter, and are in good ftate and flourifhing, though grafted on trees which drop their leaves in winter. This plainly fhews that the juices rife upwards in winter, even in thofe trees which drop their leaves, otherwife thefe grafted ever-greens muft have ftarved at that feafon.

If all the variety of foreign oaks were to be grafted on the Englifh oak, it would make the timber more firm and lafting than it is, when raifed from foreign acorns; for as the crab ftock makes the wood of the apple more firm and lafting, than that of the apple ftock, and the peaches and almonds, budded on plums, are more lafting than thofe on peach ftalks: fo, by the contrary rule, all firm timber, grafted

ed on ſpungy ſtocks, would be made worſe than it would be on its own bottom; as if the Engliſh elm were grafted upon the Dutch elm, it would partake ſo much of the nature of the ſtock, as to be a ſpungy wood, and not fit for the uſes it is uſually put to.

In grafting the New-England cedar, or juniper, upon the Virginia cedar, this experimenter found that the branch which was grafted, being left ſeveral inches below the grafting, that part continued growing, as well as the upper part above the grafting. The viburnum was another ſubject of his experiments. On bending down the top of this tree, and burying its upper branches in the earth, theſe became roots, and the proper roots were by degrees removed out of the ground as theſe took place. All the roots became branches, and finally the tree became inverted, and grew as well as in its natural ſtate.

A pear tree being inarched upon two pear ſtocks, continued in a flouriſhing ſtate, even when the root was raiſed out of the ground, and it received no nouriſhment, but from the two inarched branches. This tree, after it had ſtood ſome years in this condition, puſhed out new ſuckers from the root; which proves, that the branches are as uſeful to ſupply the root with nouriſhment, as that is to ſupply the branches; and hence it is no wonder that ſo many trees miſcarry in planting, when there are no branches left on the head. Philoſ. Tranſ. N° 384. p. 127.

SAPA, among the Romans, new wine boiled to the third part of its firſt quantity. *Pitiſc.* in voc.

SAPINDUS, the *ſoapberry tree*, in botany, the name of a genus of plants, the characters of which are theſe. The flower is of the roſaceous kind, being compoſed of ſeveral petals, arranged in a circular form; theſe are uſually four in number, and the cup is alſo compoſed of four leaves. The piſtil ariſes from the cup, and finally becomes a round fruit, which encloſes a ſtone of the ſame ſhape, with a roundiſh kernel in it.

There is only one known ſpecies of this genus, which is the *ſoapberry tree* with leaves growing to an alated rib. *Tourn.* Inſt. p. 659.

The berries of this tree are uſed as ſoap; they are of the ſize of a muſket-bullet, and are uſed in waſhing without any admixture of ſalt or oil. They perform the office of ſoap very well, as to the cleanſing the linnen, but they rot it in time.

The negroes in general uſe them for their coarſe apparel, which bears them much better than the finer linnen worn by the Europeans. Philoſ. Tranſ. N° 96.

SAPINUS, in botany, a name given by ſome of the modern botanical writers to the fir tree. This does not ſeem, however, to have been the tree ſo called by the antients. Some of thoſe writers have plainly deſcribed the pine tree under this name, and Pliny makes it the denomination of the pitch tree, ſuch as was manured in his time.

Matthiolus contends that no peculiar tree was ever called by this name, but that what the antients meant by this word, was, that part of the fir, or any other tree of that kind, which was above the ground, and below the branches. This is uſually a ſmooth part of the tree, free from knots; and the other part, where the branches grow, was called *fruſterna*. Matthiolus grounds this on the authority of Pliny, but that author errs in this; for that part of the tree was not called *ſapinus*, but expreſſed by the adjective *ſappinea*.

This is abundantly proved by Vitruvius; and on comparing the text of theſe two authors, it appears that Pliny took from Vitruvius what he ſays on this ſubject, though he did this erroneouſly; for Vitruvius ſays, that this part of the fir was called *ſappinea*, becauſe very ſmooth, and free from knots, like the *ſappinus*, or pine.

Pliny, in another place, diſtinguiſhes between the *ſapinus* and *ſappinus*. The *ſappinus* he ſeems to make the ſame with the common pitch tree, and the *ſapinus* with the pine, or with ſome other tree of the coniferous kind: he places this great diſtinction between them, that the *ſappinus*, when cut down, would never grow up again, but that the *ſapinus* would.

Some of the old gloſſaries diſtinguiſh alſo between the *ſapinus* and *ſappinus* in this manner, the one being always tranſlated the pine, πίτυς; and the *ſappinus* the fir, πεύκη. The obſervation of Pliny, of the one of theſe trees growing again from the root when cut down, and the other not, is contrary, however, to the ſentiments of the reſt of the antients.

Theophraſtus ſays of both the pine and fir, that when once cut down they never ſhoot up again; and Herodotus mentions the ſame thing, as a ſingularity among trees.

The word *ſapinus* ſeems to be only a contraction of *ſapapinus*, a name given by the Latins to the domeſtic or cultivated pine, from the vaſt quantity of juice or ſap it contained. They had a way of expreſſing this juice by the word *ſapa*; and Theophraſtus has, for the ſame reaſon, called the domeſtic pine by the name *orrus*, ὀῤῥός, a word ſignifying juice or ſap. This was the pine tree which bore the pine nuts uſed in medicine and in foods; and Pliny, who calls it the *manured pitch tree*, plainly errs, becauſe that tree cannot bear eſculent nuts, or anſwer to the reſt of the deſcription.

SAPO *amygdalinus*, *almond ſoap*, a new form of medicine got much into uſe of late in nephritic caſes, and made to ſupply the place of the common hard *ſoap* for internal uſes, in a more determinate manner for the phyſician, and a more cleanly one for the patient.

It is thus made. Take any quantity of freſh oil of almonds, and thrice its quantity of *ſoap* lees; digeſt them together in ſuch a heat as will make them but juſt boil, within a few hours the oil and lees will be united, and the liquor will ſoon after become ropy, and ſomething tranſparent, and will cool into the conſiſtence of a jelly; then throw in ſea ſalt till the boiling liquor has loſt its ropineſs; continue the boiling till drops of the liquor being received upon a tile, the water is ſeen to ſeparate freely from the coagulated *ſoap*; then take away the fire, and the *ſoap* will riſe to the top of the water, and is to be taken off for uſe. *Pemberton*'s College Diſpenſ. p. 184.

SAPONACEA *terra*, in natural hiſtory, a term uſed by ſome to expreſs a kind of native alkali *ſalt*, of the nature of the nitre, or natron of the antients, which is found on the ſurface of the earth, mixed with dirt, &c. in the neighbourhood of Smyrna, and thence called by ſome *Smyrna earth*.

It is found principally in two places near Duraclea, a large open village, about ſix leagues to the eaſtward of Smyrna; and in a very flat plain, about a league weſtward from the river Hermus. It is at firſt gathering, a fine whitiſh *ſalt*, which of itſelf boils up, as it were, out of the ground. It is always gathered before ſun-riſe, and only in mornings in which there falls no dew; ſo that a ſtock ſufficient for the whole year muſt be laid in during the ſummer months. It comes up in ſome places an inch or two above the ſurface of the ground, but when the ſun riſes upon it, it dries and falls down again. The earth producing it lies low in both places, and in winter is waſhy. It is thinly covered with graſs.

It may be ſuſpected, at firſt ſight, that the neighbouring ſea impregnates this earth about Hermus, but the ground which produces it, and lies about Duraclea, is ſo far from the ſea, that it overthrows this ſpeculation; though every morning in ſummer the earth be ſwept clean of this *ſalt*, the next morning always produces a new crop.

Dr. Smyth, who made experiments upon this *ſalt*, informs us, that three hundred drachms of it being put into a retort, and this ſet in a ſand-heat with a very ſtrong fire for twelve hours, yielded between five and ſix ounces of an inſipid phlegm, of no other ſmell but ſuch as, in all ſuch operations, ariſes from the fire. It appeared from this, that the matter contained no volatile *ſalt*. After this the quantity of two hundred drachms, calcined in a German crucible, were diſſolved in water. This compoſition of earth and water, boiled into a lixivium, made five hundred drachms, after it had boiled three hours, and the foul ſcum had been continually taken off during that time, and been filtrated; the cloſe liquor being then evaporated to a dryneſs, there remained a pure white fixed alkaline *ſalt*, of the nature of pot-aſh.

The people of the place make ſoap with this earth in the following manner. They mix three fourths of this earth with one fourth of lime, and then pour boiling water upon the mixture: they ſtir this with a ſtick, and there ariſes to the top a thick browniſh ſubſtance, which they ſcum off; they ſave this in veſſels by itſelf. They uſe both this and the clear liquor in making ſoap, but this is much ſtronger than the liquor. They put fifty kintals of oil into a large copper boiling veſſel, and kindling a large fire under it, they let the oil boil a little, and then throw in by little and little firſt the ſcum of the lye, and afterwards the liquor itſelf; though ſometimes they uſe only the one, or only the other. They continue adding more and more of theſe, till the oil acquires the conſiſtence of ſoap, which is often ſeveral days. The fire muſt be all this time kept up very ſtrong. The ſcum of the lye, and the ſtronger part of the lye itſelf, mix with the oil in the boiling, and the weaker part unmixing itſelf, ſinks to the bottom, and is let out by a cock prepared for that purpoſe. This is not thrown away, but is let run upon freſh lime and earth, to make a lye for future uſe; and when the ſoap is perfectly made, it is ladled out, and put upon a brick or lime floor to harden.

The common proportion in the making the ſoap is two loads of earth, of five kintals each, to fifty kintals of oil, and the produce is between ſeventy and eighty kintals of ſoap. The earth is bought at a dollar a load, and the ſoap at $6\frac{1}{2}$ a kintal. There is employed annually, in making ſoap at Smyrna, at leaſt ten thouſand kintals of oil. The bringing the ſoap earth to Smyrna employs a thouſand camels, or fifteen hundred, for eight months of the year, the four ſummer months being too hot for camels to travel in. A common ſoap houſe produces, at a medium, a thouſand dollars a year clear profit. Philoſ. Tranſ. N° 220. p. 230.

SAPONARIA, in the materia medica, a name given at different times to ſeveral plants, which had in ſome ſort the properties of ſoap.

The *ſtruthium* of the Greek, and *herba lanaria* of the Romans, having ſomewhat of this property, and being uſed in the cleaning of wool, ſeveral authors have explained it by the word *ſaponaria*; but this is leaving us as much in the dark, as to the plant, as we were before, not at all aſcertaining which, if any of the plants at one time or other ſo called, was to be underſtood as being the ſame with the *ſtruthium.*

The Greeks have many times called hyſſop by the name *ſaponaria*; others have given the ſame name to the anagallis, or pimpernel; and others to ſeveral different plants, which they ſuppoſed to have the effects of ſoap, or of nitre, in cleanſing of things.

None of the plants, however, that we have under the name *ſaponaria*, will at all agree with the *ſtruthium*, or *herba lanaria*, which was a thiſtle; and the very Arabians ſeem not to have known it, but have erroneouſly ſuppoſed their candiſi to be it.

SAPONARIA *terra*, in mineralogy, a name given by ſome authors to the common fullers earth. *Dale*'s Pharm. p. 19. See FULLERS *earth*, *Cycl.* and *Suppl.*

SAPONARIA *terra alba*, in natural hiſtory, a name given by ſome authors to the common tobaccopipe clay.

They call the common fullers earth alſo *ſaponaria terra*, and diſtinguiſh it from this by the epithet *purpuraſcens*; though it has no ſuch colour as purple about it. *Kentman*'s Nomenclator, foſſ. p. 1. See the article CIMOLIA.

SAPONARIUM *lixivium*. See LIXIVIUM *ſaponarium.*

SAPONEA, a name given by authors to a pectoral medicine made of oil of ſweet almonds and ſugar, mixed with the diſtilled water of violets.

SAPOTA, in botany, the name by which Plumier calls a genus of plants, ſince deſcribed by Linnæus under the name of *achras*. See the article ACHRAS.

SAPPAN, in the materia medica, a name uſed by ſome authors for the wood of the *arbor Campechiana*, or logwood uſed in dying. *Breyn.* Prodr. Vol. 2. p. 37.

SAPPHIRE, (*Cycl.*) the name given by the moderns to a beautiful pellucid gem of a blue colour: this is however extremely different from the ſtone the antients knew under the name of the *ſapphire*; for that was no pellucid gem, but an opake ſtone of a very deep blue, veined with white, and ſpotted with ſmall gold coloured ſpangles, in form of ſtars, and was only a more beautiful kind of their *cyanus*, which was the ſtone we call *lapis lazuli.*

The deſcriptions of all the authors of antiquity of the ſtone they called the *ſapphire*, plainly evince this; and hence authors of a later date have too haſtily concluded, that our *ſapphire* was wholly unknown to them: but this ſeems a very improbable conjecture, and a ſtrict enquiry into their writings will ſhew that they have very well deſcribed our *ſapphire*, under the name of *the ſky blue beryl*, or *beryllus aëroides*; and as it had among them no peculiar generical name, it could not have been better named than thus; as the beryl is plainly that of all the gems to which the *ſapphire* moſt approaches, and its colour is in the fineſt ſpecimens a pure ſky blue.

It is in its moſt perfect ſtate a very elegant and valuable gem, and is ſecond only to the diamond in luſtre, hardneſs, and price. It is met with of various ſizes, but ſeldom ſo very ſmall as many of the other gems, and has been ſometimes found up to three quarters of an inch in diameter. Its more uſual ſtandard is between a ſeventh and a ſixth of an inch. It is various in figure, being ſometimes found in the pebble, and ſometimes in the cryſtal form. Its moſt uſual appearance is in ſmall irregularly rounded, or oblong flattiſh ſtones, covered with no cruſt, and looking of a bright blue, but without the luſtre and fine poliſh of the native ruby. It is ſometimes alſo found in beautiful hexangular cryſtals, terminated by hexangular pyramids of a fine blue throughout, and naturally of a high poliſh. Sometimes alſo theſe ſprigs are only coloured at their points, and ſometimes they are wholly colourleſs.

The proper and only colour of the gem is blue; in ſome ſpecimens this is a fine deep colour, like that of the cleareſt ſky; and in others it varies into paleneſs in ſhades of all degrees, between that and the pure brightneſs and water of cryſtal, without the leaſt tinge of colour, but with a ſuperior brightneſs, that eaſily diſtinguiſhes it at ſight from cryſtal, it more than any ſtone approaching to the nature of the diamond; and in ſome it has a duſky whiteneſs, like that of milk: this laſt colour might be ſuppoſed owing to a mixture of a fine white earthy matter, but that it has been found that different mixtures of pellucid liquors, ſolutions of copper, and of different ſalts, are capable of producing the ſame colour.

It ſeems very clear, from a multitude of experiments, that this gem, in its pureſt and fineſt ſtate, owes its beautiful blue to copper; and the ſame metal being found capable of giving this milky look with a caſt of blue, the general opinion of this laſt mentioned milky looking ſtone being a true *ſapphire*, ſeems perfectly right.

The pebble *ſapphires* are always finer than the cryſtalliform ones, and moſt of the fine colourleſs *ſapphires*, which our jewellers commonly, but very improperly, call white *ſapphires*, as they have not the leaſt tinge of whiteneſs in them, but are abſolutely colourleſs, as the pureſt waters are of the pebble, not of the ſprig kind.

The *ſapphire* is of very different degrees of hardneſs and brightneſs in different parts of the world, and conſequently of very different value.

The antients uſed to diſtinguiſh the *ſapphire*, as they did all the other precious ſtones, into the male and female kind, according to the deeper or paler colour; and our jewellers, according to their cuſtom of dividing the gems into ſeveral kinds, according to their different accidents of purity, beauty, &c. make four kinds of *ſapphire.*

1. The firſt is the fine blue oriental *ſapphire.* This is the name they give the *ſapphire* when in its greateſt degree of purity and perfection, as hard as the ruby, and of a fine ſky blue.

2. The white *ſapphire.* This is the name they give the *ſapphire* when wholly colourleſs, and reſembling the diamond; and that whether it have been naturally found ſo, or reduced to that ſtate by art: for as all *ſapphires* loſe their colour on being put into the fire, it is a common practice with ſome jewellers, when they have *ſapphires* of a bad colour, to diveſt them wholly of it by fire, and bring them to what they call white *ſapphires*; but this, as before obſerved, is a very improper name, as the gem in this ſtate has not the leaſt tinge of white, but is wholly colourleſs, and as there is another white *ſapphire*, which is truly ſo, and which they call the milk *ſapphire.*

3. The third kind of *ſapphire* is what they call the water *ſapphire.* This alſo is a very improper name, not at all expreſſing what they mean by it; for they call by this name all the ſoft pale blue *ſapphires* which are found in Europe.

4. The laſt is the milk *ſapphire.* This is the name they give the *ſapphire* when of a white milky caſt, with a faint tinge of blue.

The fineſt *ſapphires* in the world are thoſe brought from the kingdom of Pegu in the Eaſt-Indies, where ſome are found perfectly colourleſs as cryſtal, and others of all ſhades of blue, up to the violet colour, but never with the leaſt tinge of purple, or any other colour but true blue: theſe are all found in the pebble form. We have other very fine *ſapphires*, both of the pebble and cryſtalliform kind, from Biſnagar, Conanor, Calicut, and the iſland of Ceylon: theſe are of all the ſhades of colour, and in Ceylon there are ſometimes found a ſort of baſtard gems, part red and part blue, ſeeming of a mixt nature between the *ſapphire* and the ruby.

The occidental *ſapphires* are from Sileſia, Bohemia, and many other parts of Europe, and are often very beautiful ſtones; but are greatly inferior, both in luſtre and hardneſs, to the oriental. *Hill*'s Hiſt. of Foſſ. p. 594.

SAPPHIRE-*colour.* To give this elegant and beautiful blue to glaſs, the workers in the glaſs-houſes uſe the following method. Take an hundred weight of rochetta fritt, and add to it a pound of prepared zaffer, and to this one ounce of manganeſe; mix all well together, and put them into the furnace to melt and purify, and when it is become perfectly pure and fine, work it into veſſels, &c. This ſmall quantity of manganeſe, with the zaffer, gives a moſt beautiful violet blue. *Neri*'s Art of Glaſs, p. 93.

SAPPHIRE-*paſte.* The method of making the counterfeit *ſapphires* in paſte is this. Take of cryſtal prepared two ounces, minium, or common red lead, ſix ounces, zaffer prepared five grains, manganeſe prepared ſeven grains; mix all the powders perfectly together, and put them into a crucible, cover it with a ſtrong lute, and put the whole into a potter's kiln, to ſtand in the hotteſt place for twenty four hours; it will be of a moſt beautiful deep *ſapphire*-colour. Blue paſtes of two other degrees of blue are alſo made in the following manner. For a ſky blue take cryſtal prepared two ounces, red lead ſix ounces, prepared zaffer twenty one grains; mix all well together, and bake them as before. For a deep violet blue take cryſtal two ounces, red lead four ounces, and four grains of painters blue ſmalt; mix all, and bake together in the kiln.

Theſe both make good blues, but much inferior to the firſt proceſs. *Neri*'s Art of Glaſs, p. 132.

SAPPHIRINA *aqua*, the *blue eye water*, is thus made. Pour a pint of ſtrong and freſh lime water into a copper veſſel; add to it a drachm of crude ſal armoniac, and throw in ſome filings, or ſmall pieces of copper, it ſoon acquires a beautiful blue colour, and is not only uſed as an eye water, but alſo to deterge old ulcers; and ſometimes is mixed with other things in injections for gonorrhœas.

SAPPHIRO-RUBINUS, in natural hiſtory, a name given by ſome modern writers on gems to a ſtone, partly a ſapphire, and partly a ruby, or, more properly ſpeaking, a ſapphire tinged in ſome part with the ruby colour, while the reſt remains

remains blue. The Indians call this *nilacundi*. *Boet*. de Boot. See NILACUNDI.

SARABARA, among the antients, a Medish or Babylonish garment, which reached only to the knees. *Pitisc*. in voc.

SARACHINUS, in ichthyology, a name given by Charleton and others to the fish, called by the generality of authors the *thrissa*, by us the *shad*, or mother of the herrings.

Authors have given names to the herring kinds, according to their different growth and size, and multiplied the species much beyond what they ought to be. Artedi observes that the *agonus* and *sarachinus* are only herrings of different growth, and that the *alausa minor* of authors is the same with the *agonus*. See the article CLUPEA.

SARACUS, in zoology, a name given by some authors to a species of sea fish of the herring kind, more usually called *agonus*, and by many suspected to have no essential difference from the *alausa* or shad, but to be the same fish in another state. *Ray's* Ichthogr. p. 226.

SARAX, in botany, a name given by some authors to the whole class of the ferns. *Ger*. Emac. Ind. 2.

SARCITES, the *flesh stone*, a name given by some authors to the cornelian, from its being of the colour of flesh; as it is very exactly in some pieces.

SARCITES, or SAURITES, is also a stone supposed to be found in the belly of a lizard; it seems to have been a species of pale cornelian. Pliny mentions it, but gives no description of it.

SARCITES, the *flesh stone*, in natural history, is also a name given by some authors to a species of stone, whose fibres were supposed to represent those of beef. It was of a black colour and firm texture.

SARCLIN-*time*, is the time or season when husbandmen weed their corn.

SARCOCOLLA (*Cycl*.)—It has been the opinion of many writers of the middle ages, that this was the gum of the beach tree. That fruit tree being very common in most parts of the world, and nothing at all like the *sarcocolla* being found to come from it, people have been led to wonder how this absurd opinion first got footing in the world; but this is easily explained by tracing up the authors who set it on foot to their origin.

Dioscorides is the great fountain, from whom all these little streams of knowledge have been supplied; and this author treating of *sarcocolla*, says, that it is the gum of a Persian tree. The words *persian tree* and *peach tree* are the same both in Greek and Latin; and hence, what he said of a tree growing in Persia, has been attributed to the peach tree; and this gum, so very different from the gum of that tree, has been supposed to flow from it.

But this is not the only confusion made in regard to this word. The later Greeks have given the name *sarcocolla* to a plant, in nothing resembling the *sarcocolla* tree. The old Greeks called both the gum and the tree, which produced it by the same name of *sarcocolla*, as they did in regard to the styrax and galbanum, and many other of the medicinal gums, and the trees and plants which produced them. But among the later Greek writers, the little plant *argemone*, an herb of the poppy kind, was called *sarcocolla*. Apuleius tells us, in his account of this plant, that the Greeks of later Ages called it *arsella* and *sarcocolla*; and Strabo confirms this, giving the same name to the same plant, only that he mistakes the Latin name, and writes *agrimonia* for *argemone*.

Marcellus Empiricus has the same observation; he says, in express words, the plants which the Greeks called *sarcocolla*, the Latins call *argemone*; and Neophytus, who describes the plant, and speaks largely of its virtues in bruises, and the like, says, that some of the Greeks call it *argemone*, some *artemone*, and others *arsella* and *sarcocolla*.

The near alliance of the sounds *argemone* and *agrimonia* seems to have deceived this author, and some others, and they sometimes give us the plant agrimony, sometimes argemone, as the *sarcocolla* of the Greeks: Neophytus is of this number, for he calls it *argemone altera*, as a plant very different from the common argemone, and his description suits with the agrimony. *Apuleii* Herb. c. 31. *Strabo* Hortul.

SARCO-EPIPLOCELE, a term used by the old medical writers, to express a compound rupture, consisting of a descent of the *epiploon* and a *sarcocele*; or a rupture of the indurated *epiploon*, whether umbilical or scrotal.

SARCOMA (*Cycl*.)—The *sarcoma narium*, by some called also *hypersarcoma narium*, is the same with what is commonly called the *polypus narium*, a caruncle of various size and consistence in the nostril. These caruncles are usually soft, extensive, and capable of elongation, but sometimes they are hard and rigid. They are sometimes pale, sometimes red, and are generally small in their beginnings, and advance but gradually; though some of them grow so fast, as to hang down out of the nose in three or four days time. They are usually not attended with pain; but some of them are hard, livid, very painful, and have a tendency to become cancerous. Some are wholly concealed in the nose, others hang down to the lips, and others, though contained in the nose, yet distend it greatly. Some are of an even surface, and others like a cluster, some descend backward through the apertures by which we draw breath through the nose into the fauces; and grow so big there as to be visible behind the uvula, and occasion difficulty of speaking and swallowing, and sometimes almost strangle the patient.

They have usually but one root, though sometimes several, and are usually formed in and from the pituitary membrane, and the disorder seems to be really no other than a morbid disposition of the spungy production and glands of this membrane. The *sarcoma* and *polypus*, though disorders of the same kind, may however be properly enough made two species; the *polypus* being soft, and hanging by a slender root, like the stalk of a fig; and the *sarcoma* of a more fleshy consistence, and adhering by a large, firm, and immoveable basis.

These disorders come sometimes from internal causes, sometimes from external injuries, and too often prove cancerous, or are attended with a spina ventosa, or caries of the bones of the nose. They may be sometimes removed by caustics, but the extirpating them with the knife is the shortest, safest, and most eligible method. *Heister's* Surgery, p. 437.

SACROMA *of the eyes*, a fleshy excrescence or tubercle formed on the inner surface of the eye-lids. These tubercles, in their beginnings, are usually small; but they, by degrees, advance often to a very considerable bulk. Some of these are of smooth surfaces, others rough and unequal, like a rasberry or mulberry.

They are always to be cured by extirpation, getting them out by a hook, a pair of plyers, or a needle and thread, and then cutting them out to the roots with scissars; the wound should be suffered to bleed a while, and afterwards washed with a collyrium made of aloes, tutty, and sugar of lead mixed in rose water, till it is perfectly healed. Some use the caustic to these tumors, but the scissars are more safe and less painful. *Heister's* Surgery, p. 374.

SARCOTHLASMA, a term used by the old physicians to express a bruise on the flesh.

SARCULATION, a term used in the antient husbandry, to express a sort of hoing, which they used among their pease and beans, and sometimes among their corn.

The *sarculum* was a sort of narrow and long hoe, with which they rooted up the weeds among plants growing irregularly. We have the same kind of instrument in use at this time in some places for hoing between the plants of flax; but one way of sowing, in rows, at present, has prevented the necessity of having recourse to so inconvenient and troublesome an instrument in other cases.

SARCULATURA, in our old writers, weeding of corn; whence *una sarculatura* was the tenant's service of one day's weeding for the lord.—*Tenet in bondagio & debet unam* sarculaturam, *&c*. *Kenn*. Paroch. Antiq. p. 403.

SARDA, the *cornelian*, in natural history, the name of a genus of the semi-pellucid gems: the characters of which are, that they are semi-pellucid stones, composed of crystal with a small admixture of earth, of a plain uniform structure, not tubulated nor crustated, and usually of one simple colour.

Of this genus there are three species. 1. The *red cornelian*, which is a very common stone among our jewellers, and is of all the degrees of red from a deep blood colour, to that of the water in which raw flesh has been soaked; and this last, if any can be called so, is its proper colour. It is usually found in a roundish, or pebble like form, and its most frequent size is between half an inch and two inches in diameter, and is found in the East and West Indies, and in many parts of Europe: our jewellers value none but the oriental, but there are very fine ones found in Silesia and Bohemia, and on the shores of the Rhine. The antients, according to the degree of colour, divided these stones into male and female, the deeper coloured ones being called the male; and our jewellers call one sort of it the beryll: this is the male *cornelian* of the antients, and is an oriental stone of a clear deep red; they have had this from the Italian lapidaries, who call every stone which is softer than the gems, and of a good colour, and capable of a fine polish, beryll, with the addition of its proper name, calling this therefore the beryll *cornelian*; and the brown crystal, the beryll crystal; but our dealers reject the proper name of the stone, and keep only the word, signifying its excellence; and both the one and the other of these substances are by them called simply the beryll. *Hill's* Hist. of Foss. p. 460.

The second species is the *yellow cornelian*. This is a stone, in the opinion of many, of greater value than the former, when in its most pure and perfect state. It is found sometimes in broad flat pieces, but more usually in the shape of our common pebbles, and is of all degrees of yellow from the deepest that can be imagined to that of a lemon peel. It is of a greater degree of transparence than the red, and in its most common state appears, when cut, like a piece of fine yellow amber. We have it principally from the East Indies; there are some specimens of it found in Germany, but they are neither very good nor very frequent, and in England we sometimes meet with large masses of it, but they are never thoroughly coloured.

The third species is the *white cornelian*. This, though less beau-

beautiful than either of the others, is however a very beautiful ſtone; it is often found in the rugged ſhape of our common flints, though not unfrequently flattiſh or roundiſh like the reſt. It is the largeſt of all the *cornelians*, being found from two to ſix inches, and often more in diameter, and is of a very beautiful colour, not a clear white, but with an admixture of blue, bringing it to a ſort of pearl colour, and is leſs tranſparent than either the yellow or the red kind. It is found in the Eaſt Indies and in many parts of Europe; France has afforded very fine pieces of it, and Germany produces it in great abundance; but the beſt next the Oriental is that of New Spain. Ibid. p. 461.

Mr. du Fay, of the academy of ſciences of Paris, accidentally hit upon a very fine way of turning any part of a red *cornelian* white, ſo as to form veins or clouds of that colour at pleaſure in it. He had obſerved, that there was a way of making figures in white upon garnets, which was done by engraving the intended figure in the ſtone, and then filling up the engraving with the common white enamel, which, when poliſhed down to the level of the ſtone, ſeemed to make one body with it, and the figure to be naturally formed in white in it. Deſirous of trying this experiment on the *cornelian*, he had one engraved, and filled up the lines with white enamel in powder, then putting it over the fire to melt the enamel, he drew it back ſeveral times, to ſee how the proceſs ſucceeded, and at length found that this ſtone would not bear the neceſſary degree of fire for the operation, but would itſelf be calcined and ſpoiled before the enamel would run: on this he ſhook out the powder, but was ſurprized to find the bottom of the engraving had all been tinged white by it, though it had not melted. To continue this trial, he laid ſome of the powder enamel on a *cornelian* that was not engraved, but only the powder was laid on in a certain figure. A ſmall degree of heat having been given to this under a muffle in a wind furnace, the parts of the ſtone which had been covered with the powder were found to be white, and the others as red as before the ſtone was put into the fire.

It appeared hence, that this coating over a part of the ſtone was ſufficient to give it a whiteneſs by the help of fire; but the curious author of this invention did not ſtop here, he ſoon found that the matter of the enamel was not neceſſary to this change, but that any other denſe ſubſtance would produce the ſame effect. The common Spaniſh white, and ſeveral other colours, were found to ſucceed very well; but the beſt of all other ſubſtances, he obſerves, is a colcothar of vitriol carefully prepared; the finer part of which being ſeparated by waſhing, and afterwards mixed up with gum water, may be uſed to draw traces ever ſo beautiful, and theſe will be all ſhewn in white upon the ſtone after it has paſſed the fire. The different parts of a figure thus delineated will be more or leſs white, as the coat of colour has been laid more or leſs thick upon the ſtone, ſo that there only requires a nice hand to draw figures ever ſo beautifully diverſified, with the ſhades of a thicker or a clearer white. The counterpart of this experiment gives alſo very beautiful figures, that is, the covering the whole ſurface of the ſtone with a coat of the colour, and then drawing the intended figure or lines cut through this coat; this being done, and the whole ſet by to dry, when it has afterwards been in the fire, all the ſurface will be found white, except where the lines were cut in, and theſe will all be beautifully red, the colour of the ſtone having ſuffered no hurt in them. Thus the figure will be expreſſed in red upon a white ground, and even the minuteſt traces drawn by the point of a fine needle will not be loſt. Mem. Acad. Par. 1732.

All *cornelians* are not equally proper for this purpoſe. Thoſe of a fine deep red, which are all of one ſimple colour, and are commonly called by our jewellers *cornelians* of the old rock, always ſucceed perfectly well, and their natural deep red ſhews the white with much beauty. The common pale *cornelians* always loſe a part of their own colour in the fire; and the *cornelians*, which have veins of different colours, or ſhades of colour, never ſucceed well, becauſe every different vein receives the tinge in a different manner. The meaner ſort of *cornelians* are ſubject alſo to crack and fly, with the degree of heat neceſſary to this operation; whereas the finer ſtones of the old rock always bear it without hurt.

It would ſeem a natural conſequence from theſe experiments, that the black agate, the coloured jaſpers, and many other of that ſort of ſtones might ſucceed as well in the delineating figures on them; but Mr. du Fay, after repeated experience, found that the *cornelian* alone would do.

SARDA, in zoology, a name by which ſome call the fiſh, more uſually known by the name of *pelamys* or *pelamys ſarda*; a fiſh reſembling a young tunny, but having larger and longer teeth and no ſcales. *Geſner* de Piſc. p. 1151. See the article PELAMYS.

SARDACHATES, in the natural hiſtory of the antients, the name of a ſpecies of agate, found frequently at this time on the ſhores of rivers in the Eaſt-Indies; and ſeeming to contain an admixture of the matter of the common red cornelian, is very excellently characterized by the name the antients gave it.

It is a very elegant and beautiful ſpecies, and is often found of a conſiderable ſize. It is of a pale whitiſh ground, and has no veins or other variegations, except a multitude of minute ſpots, of a pale red, and of the matter of the red cornelian; theſe are ſcattered very ſparingly in ſome parts of the maſs, but in others they are ſo cluſtered together, as to make ſmall clouds of an elegant red. It is very hard, and is capable of an elegant poliſh. Our lapidaries do not much eſteem it, but in ſome other places it is wrought into toys which are much eſteemed. *Hill's* Hiſt. of Foſſ. p. 483.

SARDANUS, in zoology, the name of a fiſh of the harengiform kind, caught in the Mediterranean, and common in the markets of Rome and Venice. Its body is broader than that of the pilchard, and its back green; and the line which runs along the belly is much leſs rough than in that fiſh. It is indeed eaſy to diſtinguiſh it from the pilchard, but not ſo eaſy to ſhew in what it differs from the common herring more than in ſize. It ſeems very probable, that it is no diſtinct ſpecies of fiſh; but, that the herring, like the pilchard, is always ſmaller in the Mediterranean than in the Ocean. *Willughby's* Hiſt. Piſc. p. 225.

SARDAR, in the Turkiſh military orders, the title of an officer choſen from among the caias of the Janizaries on ſome particular occaſion, ſuch as to head a detachment ſent to war, or on any other occaſion.

The word is of Perſian origin, and is derived from *ſar*, which in the language ſignifies a head or chief.

This officer is a colonel of a detached body; he is attended in his expedition by his deputy, and two ſecretaries, and his office expires at his return from the buſineſs he was diſpatched on. *Pocock's* Ægypt. p. 169.

SARDELLA, in zoology, a name by which ſome have called the pilchard of the Mediterranean ſea, ſuppoſing it different in ſpecies from that of the ocean, but it ſeems in reality to be no other than the common pilchard, only not growing ſo large there as in the Ocean. *Willughby's* Hiſt. Piſc. p. 224. See the article PILCHARDUS.

SARDINA, in zoology, a name by which many have diſtinguiſhed a fiſh of the harengiform kind, which is in reality, however, no other than a ſmall pilchard, the pilchard growing to a larger ſize in the Ocean than in the Mediterranean. *Willughby's* Hiſt. Piſc. p. 224. See PILCHARDUS.

SARDOA, or SARDOUM, in botany, a name given by the antients to the water crowfoot, with jagged leaves, called alſo *apiaſtrum* and *ranunculus apii folio*, from its leaves reſembling in ſome degree thoſe of the ſmallage. This has been in all ages charactered as a poiſon; but Pliny has found means to confound this with baum, under the name of apiaſtrum, which he ſays is fed on by the bees in Italy, but is very well known to be a dangerous poiſon in Sardinia.

SARDONIA *herba*, in botany, a name given by many of the antients to the poiſonous water *ranunculus*, which others call *apiaſtrum*, from its having leaves ſomewhat reſembling ſmallage; and our modern botaniſts call it the *ranunculus paluſtris apii folio*, or water crowfoot with ſmallage leaves.

It had the name *ſardonia* from its growing very plentifully in Sardinia. The old Greeks have generally written the name of that iſland *Sardonia*, not Sardinia; and hence they have called the plant alſo by the ſame name.

It is branded by all authors, both antient and modern, with the name of a poiſon, and we ſee that even the cattle will not touch it, though a very ſucculent and well looking herb.

SARDONYX, (*Cycl.*) in natural hiſtory, the name of a genus of the ſemi-pellucid gems, which are conſiderably tranſparent, of the true onyx ſtructure, either zoned or tabulated, and are compoſed of the true matter of the onyx, variegated with zones of that of the red or yellow cornelian.

Of this genus there are four known ſpecies. 1. The thin zoned red *ſardonyx*, or whitiſh onyx, with thin, ſnow white, and red zones; this is one of the moſt beautiful of the ſemi-pellucid gems. The ground of this is a cryſtalline matter, ſomewhat whitiſh, otherwiſe very little differing from pure cryſtal, either in colour or tranſparence; and the zones are always extremely fine and ſlender, and laid with a beautiful regularity over one another; they are of the true matter of the cornelian, and ſome are of the plain red cornelian, others of the white, and others often of a pale fleſh colour, made by an admixture of the former two. It is only found in the Eaſt Indies, and is greatly valued among our lapidaries. *Hill's* Hiſt. of Foſſ. p. 493.

The ſecond ſpecies is the broad veined red *ſardonyx*, or horny onyx, with red punctated zones. This is a beautiful ſtone, though greatly inferior to the former kind. Its ground is of a true horn colour, and much reſembles that of many of the agates of the Eaſt Indies, and its zones are of the true matter of the red cornelian, but they are broad and coarſe to the naked eye; and when viewed with a microſcope, or even only attentively examined by the naked eye againſt a good light, they are found to be each compoſed of a number of thin ones, ſeparated from each other by narrow zones of the common matter of the ſtone, and each compoſed of ſeveral cloſe arrangements of ſmall red ſpots. This is found in New Spain and in ſome parts of Europe, and is ſometimes wrought into ſnuff-boxes, counters for cards, or other toys; but is very little eſteemed.

The third species is the yellow leaved *sardonyx*, which, as its veins are as truly of the matter of the yellow cornelian, as those of the former species are of the red, is certainly entitled as much as they to the name of *sardonyx*. This is a very beautiful stone, and was well known among the antients by the name of the *onyx in qua chrysolithi color*, or the chrysolite onyx. The chrysolite of the antients was the gem we now call the topaz, and the zones of this stone are truly of that colour, though of less transparence and brightness. It is found in pretty large masses, but always flat, and full of numerous cracks and flaws, so that few pieces of it can be obtained of any size. Its zones are so many flat and regular plates or tables, laid evenly on one another, but divided by other zones of the matter of the stone: this is of a clear and beautiful pale brown, and the zones being of an extremely bright yellow, the whole is very beautiful. It is found in many parts of the world, but is no where common, it being rare to meet with two specimens of it together. Arabia, Armenia, Persia, China, and New-Spain, have all been known, at times, to produce it. In Italy it is very much valued, but with us it is hardly known.

The fourth species is the orange coloured *sardonyx*, or the bluish white onyx with orange coloured and whitish zones. This is a very singular species, and is not without its beauty, though greatly inferior to the former. Its ground, or basis, is a bluish white, and its zones are made of the matter of the deeper yellow and the white cornelian laid alternately, and often intermixed with other zones, made of the common matter of the stone. It is found in Ægypt, Arabia, and the East-Indies, and not unfrequently in Germany, but the European is greatly inferior to the Oriental.

These are all the genuine *sardonyxes*; but the stone called *sardonyx*, in Pliny's time, being properly a camæa, not a *sardonyx*, is to be seen under that head. *Hill's* Hist. of Foss. p. 497.

SARFAR, a name given by some of the chemists to iron.

SARGAZO, or SARGASO, in botany, a name for the plant commonly called *sea lentils*; a small sea plant found among the rocks, and sometimes at open sea, and supposed to be a good diuretic. *Mont.* Exot. p. 7. *Piso*, p. 18.

SARGO, the name used by Agustino Scilla, in his book of petrifactions, for the name of one of those kinds of sea fish, in the hinder part of whose jaws are found those round *dentes molares*, or grinder teeth, which, when found in a petrified state, are called *bufonitæ*, or toadstones.

It is very certain, that by *sargo* Scilla means no other fish than the *sargus*; yet Mr. Willughby says that the *sargus* has none of these round grinders, or *tubercula ossea*, as he calls them, and makes this one of the characters by which the *sargus* is to be distinguished from the sparus and scarus, and other fishes of that tribe.

It is probable that Scilla, who wrote more expresly on these subjects, dissected his *sargus* with too much accuracy, to be mistaken in this material part of it; and it is possible that Mr. Willughby, though a very accurate writer, might overlook these teeth in the hinder part of the jaw of a fish which he was only describing in the common way, and had no peculiar reason for examining in so nice a manner just in this part. Philos. Trans. N° 219. p. 195.

SARGUS, in zoology, the name of a fish well known, and much esteemed among the antients, and not uncommon at this time in the markets of Rome, Venice, *&c.* being caught in the Mediterranean and Adriatic in considerable quantities. See Tab. of Fishes, N° 54.

It something resembles the sparus in figure, but its nose is longer and more pointed, and turns up a little, and its foreteeth are shaped like two human teeth, which stand in the same part of the mouth. It has no tubercles in the hinder part of the jaws, as the sparus has; and its whole body is variegated with brown transverse rings, resembling the variegations of the perch, and has only one fin on the back, the anterior rays of which are prickly, the hinder ones not at all so. *Willughby*, Hist. Pisc. p. 309. *Gesner*, de Pisc. p. 993.

SARGUS, in zoology, is also the name of a river fish, called by others *gardon*, *sardus*, and *cephalus*, and by many supposed to be no way essentially different from our common roach.

It is a river fish, very much resembling the chub in its general figure, and the size of its scales, but it has a smaller head, and a somewhat broader body than that fish. Its back is bluish, its neck greenish, and its belly white. It has no teeth. Its eyes are yellow, and it is usually less fat than the chub.

It is a very brisk and lively fish, and is a sort of emblem of health among the French, and used proverbially as such in the same manner as the roach among us. We say of a healthy man, he is as sound as a roach, they, he is as sound as a *gardon*. It is common in the rivers of France, Italy, and Germany, and is esteemed but a moderately fine fish for the table. *Willughby's* Hist. Pisc. p. 260.

SARIGOY, in zoology, a name by which some call the creature we know by the name of the *opossum*. See the article OPOSSUM.

SARIO, in zoology, a term used by some authors for the salmon when in the middle stage of its growth, when it is past its younger state, in which it is called a *salar*, and is not yet arrived at what is properly called a *salmon*. *Willughby's* Hist. Pisc. p. 189. See the article SALMO.

SARISSA, in antiquity, a very long spear used by the Macedonians. Ælian says, that by the antient usage they ought to be sixteen cubits in length; but that in fact they were but fourteen, two cubits being allowed for the handle, and the other twelve to cover their bodies. *Pitisc.* in voc.

SARMATICA *lues*, a name given by some authors to the *plica polonica*.

SARMENIUS *lapis*, a name given by the writers of the middle ages to a stone said to be used in the polishing of gold, and to have virtues in medicine also; such as preventing abortion, and the like.

It seems to have been only a corrupt way of spelling *samius lapis*, a stone to which Pliny has attributed the same virtues.

SARMENTOUS *stalk*. See the article STALK.

SARONIA, Σαρωνια, among the Greeks, a festival kept in honour of Diana, surnamed *Saronia*, from Saro the third king of Trœzene, by whom a temple was erected, and this festival instituted to her. *Potter*, Archæol. Græc. Tom. I. p. 439.

SAROS, Σαρος, in chronology, a period of 223 lunar months. *Suidas* in voc. Σαρος Mem. Acad. Inscr. Tom. 8. p. 283.

The etymology of the word is said to be Chaldean, signifying restitution, or return of eclipses; that is, conjunctions of the sun and moon in nearly the same place of the ecliptic.

The *saros* was a cycle like to that of *meto*. See the article METONIC, *Cycl.*

SAROSEL, in the glass trade, the name of the room into which the mouth of the Leer opens, and in which the glass vessels are placed, when taken out of the Leer.

The men who attend to do this are called the *sarole* men. *Neri's* Art of Glass, p. 244.

SARPA, in zoology, the name by which the *salpa*, a very beautiful fish of the Mediterranean, is known in the Italian markets. *Gesner* de Pisc. p. 979. See SALPA.

SARPICULA, among the Romans, a term used by the old Roman writers to signify a pruning hook. *Pitisc.* in voc.

SARPLAR *of wool*, a quantity of wool otherwise called a pocket, or half sack; a sack containing eighty tod, a tod two stone, and a stone fourteen pounds. See the article SACK, *Cycl.*

In Scotland it is termed *sarpliath*, and contains eighty stone. Vid. Dict. Rust. in voc.

SARPOE, a name given to the fish called by authors *salpa*. See SALPA.

SARRACENA, in botany, the name of a genus of plants, the characters of which are these. The flower is of the rosaceous kind, and is composed of several leaves, arranged in a circular form, and placed on a one leaved cup, divided into many segments at the edges, or sometimes of a number of distinct leaves; from the center of the cup there arises a pistil, which carries on its top a sort of membranaceous shield, which finally becomes a roundish fruit, usually divided into five cells, and containing oblong seeds.

There is only one known species of *sarracena*, which is the *sarracena* with hollow and auriculated leaves, commonly called *the hollow leaved sea lavender*, the *limonio congener* of Clusius. *Tourn.* Inst. p. 657.

SARRITION, *sarritio*, in Roman authors, the term used to express what we call hoeing in husbandry, or something analogous to it, that is a way of stirring up the earth about young plants, and destroying the weeds that would grow among them. When the plants had been some time come up, they stirred the land with wooden rakes or harrows, and then went over the fields, and pulled up the weeds by hand.

Columella says, that they sowed the medica by scattering the seeds on the surface of the ground, and then raking them in with iron rakes, and that at different times. After this they went over the ground again with the same instruments, to root up the weeds which would have choaked the young plant. They both harrowed and hoed *rastris* with rakes; so that their *occatio* and *sarritio* were performed with much the same sort of instrument, and differed only in the time or season at which they were performed: the first was at seed time, to cover the grain and level the ground, and the other was to move the ground after the plants were up.

They used two kinds of *sarrition*; the one was intended only to move the ground, the other was to cover up the young plants, that they might grow the more strong and vigorously. The antients all sowed their corn under furrow; that is, they first levelled the ground by harrowing, then scattered the seed upon it, and afterwards plowed it in. This method left the ground very uneven, and the corn came up mostly in the lowest places betwixt the furrows, which always lay higher. This we see is always the case at present, where the same method is followed; and the understanding this explains a passage in Virgil, which many have been perplexed about, *cum sulcos equant sata*, when the corn is as high as the furrows, which it is plain it could not be

be in this method of hufbandry, till it was of fome growth. When they only hoed to ftir the furface of the ground, or ufed what they called plain *farrition*, they harrowed or hoed lengthways of the furrows, which being fomewhat hardened, there could be little earth thrown down thence upon the corn.

The other kind of *farrition* was performed by ftirring the earth crofsways of the furrows, by which a great deal of it muft needs be thrown down among the young corn. The hufbandmen of thefe times fuppofed, that the falling down of this earth upon the ftalk, burying it to fome depth, was the occafion of its growing ftrongly and vigoroufly: but though this could not be the cafe, it is certain that the corn did grow better for the operation, becaufe the ground was thoroughly ftirred by it, and had an advantage for the plants, like that obtained by the modern practice of horfe-hoeing.

The antients in many other cafes, as well as this, feem to have miftaken the intent and meaning of their general practices in hufbandry. Columella fays that beans, peafe, and other the like herbs, fhould all be well hoed when they are about four fingers high, excepting only the lupine, but that hoeing was injurious to this plant, which having only one root, when that was cut the whole plant perifhed.

He adds, that hoeing was not neceffary to this plant, becaufe it was of itfelf fo ftrong a grower, that it kills all weeds, ftarving them out by drawing all the nourifhment to itfelf.

If the hufbandmen of thefe times had fowed their lupines in rows, and harrowed only between thofe rows, they would have been in no danger of cutting the roots of the plant; and had they been better acquainted with hoeing, they would have known that the killing the weeds is the leaft part of the advantage arifing from it, the principal being the opening and dividing the earth, and giving it a kind of new tillage.

The *farrition* ufed by the antients fcratched only fo flight a part of the furface of the ground, that it is to be doubted whether it was of much advantage; and this was done fo indiftinctly among the corn and weeds, without favouring one any more than another, that it is a difpute whether the good it did, in facilitating the runcation, or hand-weeding afterwards, was greater than the damage it did by tearing the corn; fo that many of the hufbandmen of thofe times chofe to omit it, and only to employ the hand-weeders: but with us hoeing, when carefully practifed, is of infinite advantage, no way injurious to the corn, though wholly deftructive of the weeds.

It is an error therefore in the tranflators of the antients, to render the word *farritio* by *hoeing*, without giving any farther explication of it; for the antients truly hoed their vineyards in an exact fenfe of the word, but not their corn; neither did they plant their corn in rows, without which they could not give it their vineyard hoeing. This farculation was ufed only among fmall quantities of fown corn, and is yet in ufe for flax; for the farculum, which is a fort of very narrow hoe, is ftill ufed among the plants of flax growing irregularly, but this is too tedious and expenfive ever to have place in whole fields of corn.

If the antients hoed their crops of corn ftanding irregularly, as fown at random, they muft have made very mad work of it, fince they were at no pains to fow in rows, and hoe between them with their bidens, which was an inftrument with which they tilled many of their vineyards, and which entered the ground as deep as the plow, and was a much better inftrument than the Englifh hoe, which is very ill calculated for the office its principal bufinefs lies in, which is ftirring the ground. *Tull*'s Horfe-hoeing Hufbandry.

SARTORIUS (*Cycl.*)—This is the longeft mufcle of the human body; it is flat, and about two fingers in breadth, fituated obliquely along the infide of the thigh. It is fixed above by a very fhort tendon, in the lower part of the anterior fuperior fpine of the os ilium, before the mufculus fafciæ latæ. The beginning of its body lies in the notch, between the two anterior fpines of that bone. From thence it runs down obliquely over the vaftus internus, and other mufcles that lie near it, all the way to the infide of the knee, where it terminates in a fmall tendon, which grows broader near its extremity, and is inferted obliquely, and a little tranfverfely, in the forepart of the infide of the head of the tibia, near the fpine or tuberofity of that bone, immediately above the infertion of the gracilis interior.

The flefhy body of this mufcle is enclofed in a vagina made by the fafcia lata; its fibres in general are longitudinal, and when its lower tendon turns obliquely over toward the head of the tibia, it feems to be braced down, and fecured in its place by a tendinous frænum or vagina. *Winflow*'s Anatomy, p. 214.

SASSAFRAS (*Cycl.*) The culture of this tree is a hard tafk, it being a very difficult tree to keep long alive, though it will do very well for fome time. It will not live in greenhoufes, and hard winters kill it in the open air.

The beft way to manage it is to remove it in April into a warm and well defended place, where it will be fafe from the cold winds, and from too much open fun. It muft not, however, be under the droppings of other trees. In winter fome mulch muft be laid on the ground round the ftem, and in the fummer feafon all the weeds muft be cleared away about it.

It is brought from Virginia and Carolina, in both which places it is common.

Ximenes, an author of confiderable credit in the world, has ventured to tell us, that the chips of the *faffafras* tree put into fea water will, in a few days, render it frefh and potable. He was probably impofed on by fome perfon, in whom he placed too much confidence in this article, for experiments fhew it to be falfe; ever fo large a quantity of this wood, kept for ever fo long a time in fea water, having no fuch effect. *Redi*'s Efperienze.

The oil of *faffafras* forms into chryftals like the oil of thyme, obferved by Mr. Neuman, and which he fuppofed like to camphor. Philof. Tranf. N° 389, 390, and 450. See CAMPHOR and OIL *of faffafras*.

SASSAROLLO, in zoology, the name of a peculiar fpecies of pigeon, called by fome *columba rupicola*, or the rock pigeon.

It is of the fhape of the common pigeon, but fmaller, and has red legs, and a grey variegated back. It feems the fame with the *livia* of other authors. *Aldrovand* de Avib. See the article LIVIA.

SATISFACTION, in law, is ufed for the giving of recompence for an injury done; or the payment of money due on bond, judgment, &c. In which laft it muft be entered on record. 2 *Lill.* Abr. 495. Terms of Law.

SATURATION, in chemiftry, is the impregnation of an acid with an alkali, or of an alkali with an acid, till either will receive no more, and the mixture becomes neutral.

SATUREIA, in botany, the name of a genus of plants, the characters of which are thefe. The flower confifts of one leaf, and is of the labiated kind. It differs from thyme, in that the flowers grow fcatteredly in the alæ of the leaves; from calamint, in that they do not ftand on ramofe pedicles; and from the thymbræ, in that they are not verticillate.

The only fpecies, properly of this genus, is the common garden *favory*.

SATURN (*Cycl.*)—The ring of *faturn* fometimes difappears, concerning which we have a paper in the Philofophical Tranfactions, N° 471. fect. 9. by Mr. Heinfius of Peterfburg.

This phænomenon is rare. It ought to happen every fifteen years; but from the fituation of the earth, with refpect to the fun and to *faturn*, it happens not above once in 30 or 45 years. See Philof. Tranf. loc. cit.

SATURNIAN, *faturnius*, in antient poetry, a kind of iambic verfe ufed in fatirical writings: it confifted of fix feet, and a fyllable over, and thence called *trimeter hypercatalectus*. *Pitifc.* in voc. See IAMBIC, *Cycl.*

SATURNINE, (*Cycl.*)—SATURNINE *tincture*, *tinctura faturnina*. See the article TINCTURE.

SAUEL, in ichthyology, a name given by the Portuguefe to a kind of fifh, very frequent on the coafts of China, which by the natives is called *xiyu*. In the months of April and May vaft numbers of them are taken in the river Kiang, near Nanking: during which time one of the moft honourable of the emperor's eunuchs takes care to have feveral fhips filled with thefe fifh; which being put into the fhips alive, are buried, as it were, in ice provided for that purpofe, and in this manner preferved for the fummer's provifion of the emperor. The fhips made ufe of to carry thefe fifh to the emperor's court at Pekin, are of the neateft kind, and richly adorned; and all other veffels are obliged to make way for them. *Hofm.* Lex. univ. in voc.

SAVELIN, in zoology, the name of a truttaceous fifh of the umbla, or umbra kind, caught in the Danube, and in fome other large rivers. Its back is black; its fides fpotted with yellow fpots; and its belly and the belly fins are yellow. The fcales are very fmall, and on the head there is a very remarkable feries of fpotted lines running into a fingular figure, and furrounding the eyes, and running afterwards to the angle of the gills. The upper jaw is much longer than the lower. Its moft frequent fize is about a foot in length, but it fometimes comes up to fix or eight pound weight. It is a very fine tafted fifh. *Willughby*, Hift. Pifc. p. 195.

SAVIN, *fabina*, in medicine, is a famous hyfteric and attenuant; it promotes the difcharges by urine; but its great effect is the promoting the menfes, which it will do more forcibly than fafely, if not under very careful management.

It is kept in the fhops as an ingredient in many compofitions, but is very rarely ufed in extemporaneous prefcription. *Savin* is a fpecies of *juniper*. See the article JUNIPER.

SAVORY, in botany. See SATUREIA.

SAURITES, a ftone mentioned by Pliny, and fuppofed by the antients to be found in the belly of a lizard. It feems to have been a kind of cornelian of a pale flefh colour.

SAURURUS, in botany, the name of a genus of plants, the characters of which are thefe. The perianthium is oblong, coloured,

coloured, and permanent; it is compofed of one leaf, and ftands fideways on the amentum. There are no petals, but the cup being coloured, has been by fome taken for a flower. The ftamina are fix long capillary filaments, three ftanding on each fide. The antheræ are oblong and erect. The germen of the piftil is oval, and divided into three lobes. There is no ftyle. The ftigmata are three, and are obtufe and permanent. The fruit is an oval berry, having only one cell, and containing only one oval feed. *Linnæi* Gen. Pl. p. 155.

SAURUS, in ichthyography, a name given by fome authors to the *lacertus*, or longer gar fifh, called *agulia imperiale* by the Italians, and the *girrock* by the Englifh fifhermen. *Willughby*, Hift. Pifc. p. 232.

SAURUS, the *lizard fifh*, is alfo a name given by Salvian, and fome other writers, to a fifh of the cuculus kind, refembling the mackrel in figure and tafte, and more ufually called *trachurus*. *Salvian*, de Aquat. p. 15. See the article TRACHURUS.

SAUSTRA *beady*, in natural hiftory, a name given by the people of the Eaft-Indies to a kind of foffil, to which they attribute great virtues in medicine.

Before it is given internally, it undergoes an hundred calcinations, and feveral preparations with the juices of herbs. When the operation is over, they fay it will cure a thoufand difeafes. It has its name from thence, the word *fauftra* fignifying with them a thoufand.

It is a talcy ftone, and in its native ftate is of a reddifh colour. *Woodw.* Cat. Foff. Vol. 2.

SAUVAGEA, in botany, the name of a genus of plants, the characters of which are thefe. The perianthium is compofed of five acute and lanceolated leaves, and remains after the flower is fallen. The flower confifts of five plane, erect, obtufe, emarginated petals, which are longer than the leaves of the cup. The ftamina are numerous capillary filaments, about half the length of the flower. The antheræ are fimple. The germen of the piftil is buried in the cup. The ftyle is fimple and fhort. The ftigmata are fix; they are of an oblong figure, and of the length of the ftyle. The fruit is a covered oval capfule, confifting of one cell. The fpatha and capfule open horizontally along the middle. The feeds are fmall and numerous. *Linnæi* Gen. Pl. p. 240.

SAW *fifh*, in ichthyology, the Englifh name for the fifh called by authors the *priftes*, and *ferra pifcis*. It has thefe names from the form of its fnout, which refembles a large toothed *faw*.

According to the new fyftem of Artedi, this is a fpecies of fqualus, and is diftinguifhed from the other fpecies of the fame genus, by the name of the fqualus with a long pointed and flatted fnout, dentated on each fide. See Tab. of Fifhes, N° 5. and SERRA *pifcis* and SQUALUS.

SAWING *afunder*, a punifhment very common among the antient oriental nations. See *Pitifc.* in voc. *ferra*.

SAXIFRAGE, *faxifraga*, in botany, the name of a genus of plants, the characters of which are thefe. The flower is of the rofaceous kind, confifting of feveral petals difpofed in a circular form; from the cup of which there arifes a two horned piftil, which finally becomes, together with the cup, a roundifh, but two horned bicapfular feed veffel, which ufually contains a number of very fmall feeds.

The fpecies of *faxifrage*, enumerated by Mr. Tournefort, are thefe. 1. The common round leaved *faxifrage*. 2. The *faxifrage* with bulbs at the leaves. 3. The fmall annual fpring *faxifrage*, called rue-leaved whitlow grafs. 4. The moffy *faxifrage* with trifid leaves. 5. The trifid leaved alpine *faxifrage* with pale yellow flowers. 6. The fmall hairy trifid leaved alpine *faxifrage*. 7. The white flowered trifid leaved rock *faxifrage*. 8. The many flowered houfeleek leaved white *faxifrage*. 9. The Pyrenean houfeleek leaved *faxifrage* with crenated leaves. 10. The narrower houfeleek *faxifrage* with ferrated leaves. 11. The *faxifrage* with rounded ferrated leaves. 12. The alpine houfeleek *faxifrage* with rough leaves. 13. The purple flowered heath-like alpine *faxifrage*. 14. The blue flowered heath-like alpine *faxifrage*. 15. The long leaved pyramidal mountain *faxifrage*. 16. The fmalleft yellow flowered Pyrenean *faxifrage* with leaves like houfeleek, very clofely put together. 17. The fmalleft white flowered Pyrenean *faxifrage* with leaves very clofely fet together. 18. The fmalleft alpine *faxifrage* with bluifh green leaves bending downwards. 19. The yellow alpine houfeleek leaved *faxifrage*. 20. The broad leaved Pyrenean trifid *faxifrage*. 21. The broad leaved rigid *faxifrage* with trifid leaves. 22. The fmalleft trifid leaved Pyrenean *faxifrage* with pale yellow flowers. 23. The Pyrenean *faxifrage* with leaves partly whole, and partly trifid. And 24. the fmalleft yellow flowered moffs-like Pyrenean *faxifrage*. *Tourn.* Inft. p. 252.

In the materia medica we have two very different plants defcribed under the name of *faxifrage*; fo that the writers on thefe fubjects feem often ftrangely to contradict one another in their defcriptions, when they are really defcribing two perfectly different plants.

The one is the *faxifraga antiquorum*. This is a low plant, fomewhat refembling thyme, and its feed is of an agreeable fmell, and warm and acrid tafte. The other is the common white meadow *faxifrage*, a plant of fix or eight inches high, with roundifh leaves and large white flowers. The root of this fpecies is granulofe, or made up of a number of fmall knobs, and thefe are in moft places ufed in the fhops under the name of *faxifrage* feeds.

The feeds of *faxifrage* were once in great efteem, as a diuretic and remedy for the ftone, but they have of late loft their credit. It may be obferved, however, that we are not proper judges of what might have been the virtues of an acrid feed, while we ufe in its ftead an infipid root. *Lemery*'s Hift. of Drugs.

Golden SAXIFRAGE. See CHRYSOPLENIUM.

Red SAXIFRAGE, *faxifraga rubra*, a name given by fome botanic authors to the *filipendula* or dropwort. *Ger.* Emac. Ind. 2. See FILIPENDULA.

Yellow SAXIFRAGE, *faxifraga lutea*, a name given by Fuchfius, and fome other authors, to the common melilot. *Ger.* Emac. Ind. 2.

SAYACU, in zoology, the name of a Brafilian bird, of the fize of our chaffinch, and all over of a greyifh green colour, and very beautifully bright and fhining in the back and wings. Its beak is black, as are alfo its eyes. *Marggrave*'s Hift. of Brafil.

SAYAN, in natural hiftory, a name given by fome to a fpecies of fea fwallow. The bird whofe nefts are fo famous an ingredient in foups.

SCAB—*Crown* SCAB, in the manege, is a mealy fcurf upon the pafterns of a horfe, that make the hair briftle and ftare.

SCABBARD, in the manege, is the fkin that ferves for a fheath or cafe to a horfe's yard.

SCABBED-*heels or frufh*, in the manege, is an eating putrefaction upon a horfe's frufh, which is very hard to cure, and has a noifome fmell.

SCABIES, the *itch* (*Cycl.*)—Medical writers diftinguifh this hateful difeafe into two kinds, the benign and the malign.

The benign *itch* befide being divided into the dry and moift, is alfo diftinguifhed into the chronic, which remains on the patient for many years, and the periodic, which returns and difappears at certain periods. It is alfo divided by others into the fuperficial and profound, the firft affecting only the fkin, and arifing ufually from contagion, the other lying deeper in the blood and humors.

The malignant *itch* is of many kinds, diftinguifhed by the epithets ferine, fcorbutic, venereal, and leprous. In thefe cafes the malignant *itch* is fometimes called alfo the complicated *itch*, as it is complicated with other diforders, and is attended with various fymptoms, not properly belonging to it as the *itch*.

Signs of the itch. The moft obvious and general figns of the *itch* are the eruption of pimples, or puftules, over the whole furface of the body, excepting only the head; which contain, in the end, a fanious and ulcerous matter. Thefe puftules ufually appear firft in the hands, and fuch other parts as are moft expofed to the air, and from thefe they gradually fpread themfelves all over the body; the body is more turgid in thofe places where the puftules are fituated, than in a ftate of health; and thefe puftules are attended with a violent itching, efpecially in the night. After a few days they either break of themfelves, or are opened by fcratching, and then become fo many little ulcers; thefe, however, ufually heal of themfelves in a very little time, and leave no fcar behind them. This kind of benign *itch* occupies no part but the fkin, and indeed the matter always lies between the cutis and cuticula, whence the cutis not being deeply corroded, the cuticle eafily heals. *Junker*'s Confp. Med. p. 448.

In the *benign moift itch*, the puftules contain a large quantity of matter, and when broken difcharge a large flow of it; there is alfo round the bafis of the puftules of this kind an inflammatory red circle; and, in fine, the more plainly that appears, the greater is the fuppuration. The ulcerations, in this kind, are deeper than in the dry, and the puftules rather give a fenfation of pain and burning heat than of itching.

In the *benign dry itch*, the puftules are much fmaller than in this cafe, and are full of a limpid water; and they ulcerate the fkin more fuperficially, and caufe a violent itching, rather than any forenefs or heat in the parts.

The *malignant itch*, when of the ferine kind, called alfo by fome the fcorbutic *itch*, is dry and fcaly, and frequently fhews bloody fpots under the larger fcales. The fkin round about thefe is tinged by the ftagnating blood, fometimes to a red, fometimes to a livid, or bluifh black colour. The itching from this kind is much more violent than from the benign, and on any fudden change of the body, either to hotter, or colder, becomes almoft intolerable. When the fcabs and cuticle are fcratched off, as is very frequently the cafe, the cutis underneath is feen red and bloody, but neither blood nor lymph are difcharged from the fcabs in fome cafes, in others a yellowifh ferous liquor runs out, and almoft immediately hardens into a fcab or cruft like that which was pulled off.

The venereal or pocky itch. This is ufually rather dry than moift, and does not fpread itfelf fo quickly as the other kinds. It fometimes occupies the body in general, fometimes only particular places, as the thighs, the fcrotum, or the face.

At its firſt appearance there are uſually felt certain little tumors under the ſkin; and after this there appears a ſcab which remains on the part a conſiderable time, and will not eaſily be removed or torn off. The pain of this is ſharp and eroſive, eſpecially when it is exaſperated by ſcratching; and while this is fixed to ſome one part, there are pains felt deep within the fleſh in other places, which are moſt intolerable in the night; and in women the fluor albus, or whites, is uſually an attendant on it; and in men ſometimes a gonorrhœa, ſometimes bubos and other tumors; and in infants, who are thus affected, from the diſeaſes of their parents, there are frequent excoriations, and often criſtated and verrucoſe excreſcences of fleſh about the anus.

The leprous itch. In this the head is frequently affected, the pains are very violent, and the hair and ſkin very frequently fall off. There iſſues from the ſcabs white ſanious matter, and the whole texture of the ſkin is altered; the cuticle being beſet with ſmall ſcales, and feeling rough like the ſkin of an elephant, whence the diſeaſe has been called by ſome *elephantiaſis*.

In other reſpects, this complaint is attended with no ſenſation of pain, or uneaſineſs; but the face is inflated, the teeth become black, the breath becomes fœtid, and tumors of the bubo kind appear on ſeveral parts of the body, all which become finally malignant ulcers; and in the progreſs of the diſeaſe, large ſcabs, with portions of the ſkin, fall from different parts of the face.

Perſons ſubject to the itch. Theſe are principally men of a ſanguineous temperament of body and phlegmatic diſpoſition, who moſt eaſily fall into the moiſt *itch* of the ſimple benign kind, and are of all others moſt difficultly cured of it. Thoſe, on the other hand, who are moſt ſubject to the ſimple dry *itch* are men of a dry temperament and choleric habit. All perſons who eat coarſe foods, with much ſalt, and drink ſour or decayed liquors, eaſily fall into this kind; as alſo ſuch as live in a damp foggy air, and thoſe who are ſubject to obſtructions of the liver, and who have long been afflicted with quartans. Thoſe who have a ſuppreſſion or diminution of the uſual quantity of urine, and by that means have the ſalt ſeroſities of the blood not duly carried off, are alſo more ſubject than others; as alſo, from the ſame cauſe, are ſuch as have had old ulcers ſuddenly ſtopped, or iſſues dried up; people who have been uſed to cupping, at certain regular times, and afterwards neglect it; and finally, thoſe of an idle and ſedentary courſe of life. Ibid. p. 450.

Cauſes of it. The cauſes of the ſimple benign *itch* are a ſtaſis and corruption of the lymphatic humors, and this is often occaſioned by the humid temperament of the air, which in cold ſeaſons prevents the going off of thoſe humors by ſweat, which had been directed to the ſkin by nature for that purpoſe, hence they remain there and corrupt; and there are other things which more or leſs concur to cauſing it; theſe are a change of the food and drink continued for ſome time, and with this a plethoric habit of body. It is ſometimes the criſis of other diſeaſes, as of a quartan, &c. Theſe are the cauſes, and theſe the perſons ſubject to the *itch*, as a primary diſeaſe beginning with them; but its uſual method of propagating itſelf is by contagion; fifty people, at leaſt, having it by this means, for one, on whom it appears of itſelf. A free uſe of ſalted food greatly exaſperates the *itch* in all perſons, but this alone can have but little effect toward the original producing it. The malignant or complicated *itch* owes its origin to other cauſes. The ferine *itch* is always cauſed by the ſcurvy, and the venereal or pocky *itch* owes its origin to a corruption of the lymph in the venereal diſeaſe.

Prognoſtics in the itch. The ſimple benign *itch*, of the moiſt kind, is the mildeſt of all the kinds, and in general the moſt eaſily cured; but as it is more ſubject to ulcerations than the other kinds, this ſometimes makes the cure in bad habits of body more difficult. The dry *itch* is more troubleſome, and takes more time in the cure than the moiſt, and is more troubleſome to the patient; but in the moiſt ſanious and ſuppurating *itch*, when it is raſhly treated by mercurial and ſulphureous ointments, by quickſilver girdles, by aſtringents and refrigerants, and is driven in, which is a very common caſe, there always ariſe very unhappy ſymptoms, ſuch as anxieties of the præcordia, aſthmas, ſuffocative catarrhs, intermittent fevers, and ſometimes inflammatory acute ones, both which are of a different appearance from thoſe diſtempers in their uſual ſtate; not unfrequently alſo terrible chronic complaints are brought on by this, as cachexies, anaſarcas and œdemas. The *itch*, in general, when newly caught by infection, is always much more eaſily cured, than when it ariſes from a fault in the humors, and is conſequently much more deeply rooted: for the ſame reaſon, the chronic *itch* is of all others the moſt difficult to be cured; and where there concurs with it a defect or fault of ſome of the viſcera, as is too often the caſe, the cure is yet greatly the more difficult. The malignant *itch* is always much more deeply rooted in the patient, and of conſequence is much more difficult of cure than the ſimple; and in particular, the ferine or ſcorbutic *itch* is one of the moſt ſtubborn diſeaſes we know of. In this caſe the food, and other circumſtances, often make the cure much more difficult than it naturally would be: poor people are often infeſted with this; and their diet not being in their choice, are with difficulty cured of it. The venereal *itch*, though generally accounted the moſt terrible of all the kinds, is yet much more eaſily cured than the ſcorbutic, and ſometimes than the ſimple chronic kind, when treated in a proper manner. *Junker's* Conſp. Med. p. 452.

Method of cure. The corrupt ſtate of the humors is to be corrected according to the ſeveral kinds. In the benign *itch*, this is effected by alexipharmics and diuretics, ſuch are decoctions of the woods of guaiacum, ſaſſafras, and the like, with elecampane and pimpernel roots, and the common abſorbents ſated with acids, as the crabs eyes, or oiſter ſhells, ſaturated with lemon juice, or the like; and the acrimony of the humors is greatly taken off by ſulphur and nitre given in powders, or by the ſimple balſam of ſulphur in oil of almonds. After this external applications compleat the cure; of this kind are the mercurial ointments, and thoſe which contain ſulphur. In the dry *itch* fomentations and baths do much more than ointments; of this kind are decoctions of the oxylapathum root, and a lixivium of quick-lime and ſulphur, or the general bathing in mineral ſprings.

In the malignant itch, the ferine or ſcorbutic is to be treated as the ſcurvy, to which it owes its origin. The antiſcorbutic juices ſhould be taken for ſome time, and the decoction of tobacco made very ſtrong, is a good external application; mercurial ointments have alſo their uſe here, and the violent heat of the eruptions may be mitigated by camphor, and by the frogs ſpawn plaiſter.

In the venereal itch, the method to be uſed for a cure is the ſame with that for the venereal diſeaſe in any other appearance, but in this there muſt be always kept up a gentle perſpiration: mercurial ointments have peculiarly a place here: and when the diſeaſe is ſo rooted as to give way to no other means, recourſe is to be had to a ſalivation; and finally, the cure is to be completed by evacuating the corrected humors by ſtool, in which caſe calomel is a very uſeful ingredient in purges, and the decoctions of the diaphoretic and diuretic vegetables are of great ſervice in compleating it, and preventing a return. Ibid. p. 454.

SCABIOSA, *ſcabious*, in the Linnæan ſyſtem of botany, a diſtinct genus of plants; the characters of which are, that there is both a common and a proper perianthium, of which the latter is alſo double. The common perianthium is expanded, and compoſed of many leaves, and containing many flowers; its leaves are inſerted in the receptacle, and ſurround it in various ſeries, the inner ones becoming gradually leſs than the outer. The proper perianthium is double, but both are fixed on the germen of the piſtil. The outer perianthium is ſhort, membranaceous, and folded, and remains after the flower is fallen; the inner is divided into five ſegments, which are narrow, and pointed; the flowers are monopetalous, they are placed erect, and the petal forms a tube, which is widened at the extremity, and ſlightly divided either into five, or four ſegments, the exterior of which are the larger. The ſtamina are four ſmall and weak filaments. The antheræ are oblong, and laid cloſely upon them. The germen of the piſtil is placed below the proper receptacle of the flower; and is incloſed, as in a caſe, in its proper vagina. The ſtyle is ſlender, and of the length of the flower. The ſtigma is obtuſe, and is obliquely rimmed round the edge. The ſeeds are ſingle to each flower, of an oval oblong figure, and crowned with their proper cups, and contained in the common receptacle, which is convex, and divided by the perianthia of the ſeveral flowers. See Tab. 1. of Botany, Claſs 12. and *Linnæi* Gen. Plant. p. 23.

The characters of this genus, according to Tournefort, are theſe. The flower is of the floſculous kind, and is compoſed of ſeveral unequal floſcules, contained in one general or common cup. Thoſe floſcules, which are placed in the middle of the flower, are divided at the ends into four or five ſegments, and thoſe which make the outer circle or rim of the flower are bilabiated. Each of theſe ſtands on the coronated top of an embryo, and each is contained in its proper and peculiar capſule, which afterwards becomes either a ſimple or a funnel faſhioned capſule, containing a coronated ſeed. *Tourn.* Inſt. p. 464.

The ſpecies of *ſcabious* enumerated by Mr. Tournefort are theſe. 1. The common hairy field *ſcabious*, or *ſcabious* of the ſhops. 2. The greater *ſcabious* with purpliſh blue flowers. 3. The broad leaved white ſhrubby *ſcabious*. 4. The broad leaved ſhrubby *ſcabious* with bluiſh flowers. 5. The tall annual *ſcabious* with leaves like agrimony. 6. The narrow leaved white flowered ſhrubby *ſcabious*. 7. The larger white flowered, narrow leaved ſhrubby *ſcabious*. 8. The yellow flowered *ſcabious* with multifid leaves. 9. The double headed white *ſcabious*. 10. The broad leaved white proliferous *ſcabious*. 11. The proliferous *ſcabious* with gingidium leaves. 12. The ſmall fine leaved poliferous *ſcabious*. 13. The Alpine *ſcabious* with great centaury leaves. 14. The ſmooth mountain *ſcabious* with leaves like the common *ſcabious*. 15. The red flowered mountain *ſcabious* broad not

jagged leaves. 16. The red flowered mountain *ſcabious* with broader and longer undivided leaves. 17. The *ſcabious* with the virga paſtoris, or ſmall dipſacus leaf. 18. The narrow leaved ſilvery *ſcabious.* 19. The long headed red flowered exotic *ſcabious.* 20. The long headed *ſcabious* with fleſh coloured flowers. 21. The long headed *ſcabious* with variegated flowers. 22. The long headed *ſcabious* with blackiſh flowers, with the ſmell of civet. 23. The proliferous Indian *ſcabious.* 24. The Portugal *ſcabious* reſembling the Indian. 25. The greater round headed *ſcabious*, called the leſſer *ſcabious.* 26. The leſſer round headed *ſcabious.* 27. The leſſer *ſcabious* with deeply divided leaves. 28. The little *ſcabious* with ſweet ſcented heads. 29. The great leaved Spaniſh ſtarry *ſcabious.* 30. The ſtarry *ſcabious* with great jagged leaves. 31. The leſſer or ſea ſtarry *ſcabious* with jagged leaves. 32. The ſmalleſt ſtarry *ſcabious.* 33. The ſtarry *ſcabious* with undivided leaves. 34. The annual proliferous ſtarry *ſcabious.* 35. The Sicilian *ſcabious* with heart-wort leaves. 36. The ſhrubby procumbent mountain *ſcabious*, with leaves like the young leaves of the achillea. 37. The Sicilian ſhrub *ſcabious* with laureola leaves hoary underneath. 38. The ſhrub *ſcabious* with ſtock July flower leaves. 39. The narrow leaved umbelliferous and proliferous *ſcabious*, with leaves cut into the middle rib. 40. The fleſh coloured flowered *ſcabious*, with leaves like the hairy jagged devil's bit. 41. The great tree *ſcabious* of Africa, with undivided, wrinkled, and crenated leaves. 42. The ſmall ſea *ſcabious.* 43. The cut leaved *ſcabious* with large flowers in membranaceous cups, and with woolly ſeeds. 44. The leaſt annual erect *ſcabious* with angular ſeeds. 45. The daiſy leaved annual *ſcabious.* 46. The greyiſh hoary Pyrenean *ſcabious* with large flowers. 47. The ſmooth graſſy leaved *ſcabious.* 48. The hairy creeping Alpine *ſcabious* with divided leaves. 49. The *ſcabious* with hairy undivided leaves, called the devil's bit. 50. The *ſcabious* with ſmooth undivided leaves and blue flowers. 51. The *ſcabious* with undivided leaves and white flowers. 52. The fleſh coloured flowered *ſcabious* with undivided leaves. 53. The *ſcabious* with whole leaves, proliferous heads, and blue flowers. 54. The *ſcabious* with leaves like fraxinella. *Tourn.* Inſt. p. 465.

The muſk *ſcabious* and other garden kinds are propagated by ſowing their ſeeds in May or the beginning of June, and the next year they will be very ſtrong, flowering from June to September, and producing ripe ſeeds, which they will not do if ſown early in the ſpring, and ſo made to flower the ſame year. The ſeeds are to be ſown on ſhady borders, and at Michaelmas the young plants are to be removed to the places where they are to remain. They are very hardy, and ſeldom periſh, till after they have ripened their ſeeds. *Miller's* Gardner's Dict.

The common *ſcabious*, of our corn fields, is accounted a great alexipharmic and pectoral; it is made an ingredient in ptyſans, and infuſions given in coughs and all diſorders of the lungs, and is recommended greatly by authors in pleuriſies, quinzies, coughs, aſthmas, and conſumptions. Some even recommend it in malignant fevers, and even in the plague.

It is alſo uſed externally, either in a ſtrong decoction, or elſe boiled into an ointment with lard in the itch, and many other diſorders of the ſkin.

Scabious, though ſo much celebrated with us for its medicinal virtues, has been ſuppoſed by many to have been wholly unknown to the antient Greeks: others who could not give into the opinion of their not knowing ſo common a plant, have ſuppoſed the *ſtæbe* of Theophraſtus and Dioſcorides to be the plant we call *ſcabious*, but there is no more juſtneſs in this than in the former opinion.

The antient Greeks knew two very different plants by the name of *ſtæbe*, but neither of theſe at all anſwered to the characters or virtues of *ſcabious*; the one was a ſhrub, the other an aquatic plant with woolly leaves. The ſhrub called *ſtæbe* was the ſame with the *pheos* and *hippopheos*, a prickly ſhrub of a cubit in height, but very full of branches, which grew on the ſhores of the iſland of Crete, and other the like places; and the plant *ſtæbe* was a ſmall gnaphalium, or cudweed, growing in wet places, and uſed for the ſtuffing of beds, and the packing up of earthen ware, and other brittle things, to prevent their breaking. The other was uſed by the fullers about cloaths.

It is ſufficiently evident, from theſe accounts, that neither the one nor the other of theſe *ſtæbes* had any of the qualities of *ſcabious*; but though neither of theſe was *ſcabious*, yet it does not follow that *ſcabious* was unknown.

Dioſcorides and Theophraſtus have deſcribed a plant called *pſorice*, from its virtues in curing cutaneous eruptions; and this agrees, in all reſpects, in figure, as well as qualities with our *ſcabious*. The later Greek writers have called this *pſora*, and thus it ſtands in Aëtius, and many others.

In times long after theſe, however, the names were forgot, though the plant and its virtues remained well known; the modern Greeks willing to deſcribe ſo uſeful a plant, but ignorant of its name, in their own language, called it *ſcampiuſa*, a name formed out of the Latin word *ſcabioſa*, by the common change of *b* into *mp*, and *o* into *u*. This was long retained in uſe; and as it was common with the Greeks to leave out the initial letter, *ſ*, in many words, ſo they ſometimes wrote this *campiuſa*.

Fuchſius, who was very deſirous of underſtanding the writings of Myrepſus, confeſſes, that he knew not what to make of the words *ſcampiuſa* and *campiuſa*, which he ſo frequently met with in that author; but though he gives no deſcription of the plant, the virtues he attributes to it are thoſe of *ſcabious*; and the names are ſo eaſily diſcovered to be derived from the Latin *ſcabioſa*, that there is no room for doubt of its being the ſame plant.

SCABROUS *leaf*, among botaniſts. See LEAF.

SCABROUS *ſtalk*. See the article STALK.

SCAD, the Engliſh name of a fiſh of the cuculus kind, reſembling the mackrel in ſhape, called by writers the *trachurus*. *Willughby's* Hiſt. Piſc. p. 290. See TRACHURUS.

SCÆNANTH, or SCHÆNANTH, in the materia medica, the dried ſtalk of a plant brought to us from Arabia.

This plant is called, by the generality of botaniſts, *juncus odoratus* and *aromaticus*; but Linnæus gives it the name of *iſchæmum*, under which head its botanical characters are deſcribed. See ISCHÆMUM.

The ſtalk is uſually eight or ten inches in length, ſometimes conſiderably more; it is ſmooth and gloſſy on the ſurface, and about the thickneſs of a wheat-ſtraw, but much more rigid and firm. It is round, jointed, and not ſolid, but has a cavity in it filled with a central pith like that of our common ruſhes. Its colour is yellowiſh at the baſe, or toward the root, but toward the top it is purpliſh or greeniſh; it is very light, yet conſiderably hard, and is of a fragrant or aromatic ſmell, in which we may diſcover ſomething of a mixed ſcent, between that of the roſe and pennyroyal. Its taſte is acrid and bitteriſh, but not unpleaſant.

It ſhould be choſen freſh, ſound, and clean, not duſty or decayed, of a good ſmell and ſtrong acrid taſte. *Hill*, Hiſt. Mat Med. p. 413.

The word *ſchænanth* ſignifying the flower of the ruſh, might naturally lead us to ſuppoſe, that what we now receive under that name, is not the drug that was ſo called by the antient Greeks and Romans, and ſome have very vigorouſly ſupported this opinion. But on enquiry into the Grecian materia medica, we find that none of their *ſchænanth* had flowers on it any more than ours.

Among the moderns, Garcias tells us, that though he bought up vaſt quantities of this drug in the Indies to ſend into Portugal, he never ſaw ſo much as one flower upon any of it; and among the antients Galen makes the very ſame obſervation. He ſays he wonders how this drug obtained the name of *ſcænanth*, for that he never met with any one piece that had a flower upon it. The reaſon alledged for this is very frivolous and trifling; namely, that the camels of that part of the world where it grew, cropped off the tops, and with them the flowers; but among the vaſt quantities of this drug, at one time or other ſent, there would be found ſome that had eſcaped the mouths of theſe creatures, and have preſerved its fine flowers, had it any ſuch as are aſcribed to it; ſo that the opinion advanced, by ſome, of its having flowers like roſes, is wholly falſe and groundleſs.

Anthos was a word uſed by the Greeks, as its Engliſh flower is, to ſignify the moſt perfect, or beſt of any kind of thing. We call the fineſt ſpecies of any thing the flower of it, and thus they called the fineſt gold the anthos and anthimion of gold, in the ſame manner this ruſh was called *ſcænanth*, or the flower of ruſhes, not for its being full of flowers, but for being the moſt excellent and valuable of all kinds of ruſhes.

The very oldeſt among the Greek writers do not uſe the term *ſcænanth*, but they call this drug *juncus aromaticus*, or *juncus odoratus*, σχοῖνον ἀρωματικὸν, and σχοῖνον εὐώδη. are the names it goes by. Hippocrates calls it by the latter of theſe names; and Meleager, though he mentions it as an herb to be put into the poets crowns, yet ſays nothing of any flowers it has, but recommends it for its fragrant ſmell.

The antients uſed the whole plant in medicine, ſtalk, leaves, and flowers; its virtue reſiding pretty equally in every part of it, as is manifeſt from every part's poſſeſſing the ſame ſmell and taſte, and having the ſame pungency in the mouth. They preſcribed it as a deobſtruent and promoter of the menſes, but at preſent it is never heard of in extemporaneous preſcription, only kept as an ingredient in ſome compoſitions. Id. ibid.

SCALARE, in natural hiſtory, a name given by Rumphius to a peculiar ſpecies of *turbo*, or *ſcrew ſhell*; the ſeveral wreaths of which having an opening between them form an open ſpiral. See TURBO.

SCALE, (*Cycl.*)—Many have been the diſputes among antient and modern muſicians, about the conſtitution of muſical *ſcales*. Some of the antients, with Euclid, will have it compoſed of tones major, and limma's; ſo that the ſeven intervals of an octave would be thus expreſſed, $\frac{9}{8}$, $\frac{256}{243}$. $\frac{9}{8}$, $\frac{9}{8}$, $\frac{256}{243}$, $\frac{9}{8}$, $\frac{9}{8}$ Some modern authors have from hence inferred the imperfection of the Greek muſic. They alledge, we here find the ditonus, or an interval equal to two tones major

major expreffed by $\frac{81}{64}$, inftead of the true third major expreffed by $\frac{5}{4}$. As there can be no queftion of the beauty and elegance of the latter, the former therefore muft be out of tune by a whole comma, which is very fhocking to the ear. In like manner, the trihemitone of the antients falls fhort of the third minor by a comma; which is alfo the deficiency of their hemi-tone, or limma, from the true femi-tone major, fo effential to good melody. All which errors would make their *fcale* appear much out of tune to us. A late learned author [a] fays he readily grants the objection, but adds, that fuch a *fcale* alfo appeared out of tune to the antients themfelves; fince they exprefsly tell us, that the intervals lefs than the diateffaron, or fourth, as alfo the intervals between the fifth and octave, were diffonant, and difagreeable to the ear. Their *fcale* here mentioned, and called by fome *fcala maxima*, was not intended to form the voice to fing accurately, but was defigned to reprefent the fyftem of their *modes* and *tones*, and give the true fourths and fifths of every key a compofer might choofe. Now if inftead of tones major and limmas we take the tones major and minor, with the femi-tone major, as the moderns contend we fhould, we fhall have a good *fcale* indeed, but a *fcale* adapted only to the conciunous conftitution of one key; and whenever we proceed from that into another, we find fome fourth or fifth erroneous by a comma. This the antients did not admit of. If to diminifh fuch errors, we introduce a temperature, we fhall have nothing in tune but the octave: fo that this *fcale* of the antients was not deftitute of reafon, and no good argument againft the accuracy of their practice can from thence be formed [b].—[[a] Dr. *Pepufch*, ap. Philof. Tranf. N° 48. p. 268. Ibid. p. 269.]

The names of the notes of the Greek *fcale*, fee under the head DIAGRAM.

Hour SCALE. See the article HOUR.

SCALES, in natural hiftory. What the naturalifts underftand by *fcales*, are certain flat and femipellucid bodies, common to the fifh, the ferpent, and the lizard kind; confifting of a fubftance fomewhat analogous to that of the horns and hoofs of other animals, as is found by cutting and burning them, and by their fmell.

The *fcales* in fifhes are of fo many different kinds and fhapes, that they afford, in many cafes, very good characters for the diftinction of the fpecies. The differences of thefe parts of fifh arife from their number, fituation, figure and proportion, and to fome other qualities peculiar to a few of them. Their differences, in regard to number, are thefe. There are none on feveral kinds of fifh, as on the petromyza, the dolphin, and the whales. Upon fome other fifhes they are but very few in number, as on the conger, the eel, the clariæ, &c. And they are on others found in vaftly great numbers, and placed in clufters one over another, as in the pearch, falmon, &c.

In regard to their fituation they differ in thefe particulars. 1. On fome fifh they are placed extremely thick and clofe upon one another. 2. In others they ftand in imbricated rows. The efoces give us an example of the firft, and the cyprini, in general, of the fecond kind. And 3. in fome they are fcattered, and at fuch diftances, that they do not touch one another; as in the congers, the eels, the clariæ, &c. Their differences in figure are not lefs evident than thofe in pofition. 1. Some are roundifh, as thofe of the clupeæ and falmons. 2. Some are oval, or of an oblong round figure, as thofe of the gadi. 3. In fome fifh they are ftrait on one fide, and rounded on the others, as in the pearch and mullet. The proper defcription of thefe is, that they have a rectilinear bafe, and rounded fides.

Their differences in proportion are thefe; they are either in regard to one another, or to the *fcales* of other fifhes, or according to our fenfes, in regard to the fize of the fifh, either very large, great, fmall, middling, or extremely minute. Thefe are words, which give a fort of ufeful idea in the defcription, though they are far from being determinate or regular in their fignifications. As to the other peculiar qualities of the *fcales* of fifhes, they are in fome foft and fmooth, as in the falmon and cyprini; and in others hard and rough, and as it were a little prickly: of this fort are the *fcales* of the pearch, the caprifcus, and fome of the pleuronecti. *Artedi*, Ichthyol.

Scales of fifhes make a fet of very curious objects for the microfcope; they are formed with a furprifing beauty and regularity, and in the different kinds exhibit almoft an endlefs variety in their figure and contexture. Some are longifh, fome round, fome triangular, and fome fquare; and there are others of all the fhapes that can well be imagined. Again, fome are armed with fharp prickles, as thofe of the foal and pearch; others have fmooth edges, as thofe of the cod, tench, carp, &c. and there is a great variety even in the *fcales* of the fame fifh; for the *fcales* of the back, belly, fides, and head, are all different in fhape and arrangement: thefe bear a very great analogy to the feathers, as they are called, on the wings of butterflies.

Thefe *fcales* are not fuppofed to be fhed every year, nor during the whole life of the fifh, but to have an annual addition of a new *fcale* growing over, and extending every way beyond the edges of the former, in proportion to the fifhes growth; fomewhat in the manner as the wood of trees encreafes annually, by the addition of a new circle next the bark. And as the age of a tree may be known by the number of ringlets its trunk is made up of, fo in fifhes, the number of plates compofing their *fcales* denote to us their age. It is alfo probable, that as there is a time of the year when trees ceafe to grow, or have any farther addition to their bulk, the fame thing happens to the *fcales* of fifhes; and that afterwards, at another time of the year, a new addition, encreafe, or growth begins.

Mr. Lewenhoek took fome *fcales* from an extremely large carp, forty two inches and a half long, Rynland meafure, which were as broad as a dollar; thefe he macerated in water, to make them cut the eafier, and then cutting obliquely through one of them, beginning with the firft formed, or very little fhell in the center, he by his microfcope plainly diftinguifhed forty lamellæ, or *fcales*, glewed as it were to one another; whence he concluded the fifh to be forty years old.

It is generally imagined that an eel has no *fcales*; but if the flime be wiped clean away, and the fkin then examined by a microfcope, it is found covered with extremely fmall *fcales*, ranged in a very orderly and pretty manner; and probably very few fifhes, except fuch as have fhells, are truly free from *fcales*.

The way of preparing *fcales* for the microfcope is to take them off carefully with a pair of nippers, wafh them very clean, and then place them between the leaves of a book to make them dry flat; and when thoroughly dry, they are to be put between two flips of talc. The fnake, viper and eft afford alfo a very beautiful and very different feries of *fcales* from thofe of fifhes. *Baker*'s Microfcop. p. 237. *Lewenhoek*'s Arc. Nat. Tom. 3. p. 214.

SCALENI, (*Cycl.*) compound mufcles irregularly triangular. The antients call them only two in number; afterwards they were divided into fix, three lying on each fide, but ufually there are only two on each fide, one lying upon the other.

The firft, or *fcalenus primus*, is fixed to the upper parts of the outfide of the firft rib by two portions, commonly called its anterior and pofterior branches; the anterior is fixed to the middle portion of the rib, about an inch from the cartilage; and the pofterior more backward in the firft rib, an interftice of about an inch being left between it and the other branch; and they are both, at their other extremities, inferted in the tranfverfe apophyfes of the vertebræ of the neck.

The fecond, or *fcalenus fecundus*, is fixed a little more backward in the external labium of the upper edge of the fecond rib; fometimes by two feparate portions; and fometimes without any divifion. The anterior portion is fixed immediately under the pofterior portion of the firft *fcalenus* by a fhort flat tendon, and is afterwards fixed by infertions, partly tendinous, and partly flefhy, in the tranfverfe apophyfes of the four firft vertebræ of the neck. The pofterior portion is fixed in the fecond rib, more backward than the other, and from thence is divided into two portions, and runs up to the tranfverfe apophyfes of the vertebræ of the neck; where the firft is inferted in the three firft vertebræ, the other only in the two firft. The vertebral infertions of both the *fcaleni* vary, being fometimes confounded with each other, and fometimes with thofe of the neighbouring mufcles. *Winflow*'s Anatomy, p. 230.

SCALENUS *lateralis*, in anatomy, a name given by Albinus to a mufcle, called by Cowper and others *fcalenus fecundus*, and by Winflow, and the French anatomifts, *portion anterieur du feconde fcalene*. Morgagni calls it *fcaleni pars a cofta fecunda enata*; and Fallopius defcribes it under the name of *octavi thoracis mufculi pars quæ inferitur in fecundum*.

SCALENUS *medius*, in anatomy, a name given by Albinus to a mufcle called the fecond *fcalenus* by Douglafs, and the third *fcalenus* by Cowper. The French call it by the name given by Winflow, *la portion ou branche pofterieure du premier fcalene*; and Vefalius has defcribed it under the name of *pars tertii et quarti dorfum moventium*.

SCALENUS *minimus*, in anatomy, a name given by Albinus to a very fmall mufcle, which other writers on this fubject have omitted to defcribe, and which the author acknowledges to be fometimes wanting.

It is very fmall, and arifes from the upper edge of the firft rib, and has two caudæ; the one of which is inferted into the lower part of the fpine, and the other a little higher. It often wants one, and fometimes the other, or latter of thefe two caudæ, and is of the fame ufe with the other *fcalenus*.

SCALENUS *pofticus*, in anatomy, a determinate name given by Albinus to one of the *fcaleni*, too much confounded by other authors with the reft of the mufcles of that name, as they are in general with one another.

This is the mufcle defcribed by Fallopius under the name of the *nonus thoracis mufculus*, and by Morgagni under the name of the *fcaleni pars a fecunda cofta enata*. The French

call it *la portion posterieure du second scalene*; a name given it by Winslow.

SCALLION, or ESCALLION, a sort of onion which never forms any bulb at the root, but is used green in spring, before the other sorts sown in July are large enough.

This is however very scarce in London, the gardiners usually selling in its place the shoots of such decayed common onions, as have sprouted in the house. These they plant in a bed early in the spring, and they soon grow large enough for use, when they pull them out; and taking off all the old outer coat of the roots, they lay them in bunches, and sell them at market for *scallions*.

The true *scallion* is easily propagated by parting the roots in autumn, and planting them three or four together in a hole, at six inches distance. These will grow in any soil or situation, and will multiply very quickly, and in a very great abundance; and their being hardy enough to endure the severest winter, and fit for use so early in spring, makes them worthy a place in all kitchin gardens. *Miller's* Gardner's Dictionary.

SCALLOP. The anatomy of this fish lets us greatly into the knowledge of the structure of the parts of other bivalve shell fish.

The *scallop* is composed of two shells, which, as in many others, are one concave, and the other plane or flat. The cardo, or hinge, is lightly bent from the concave shell, and thence carried over a part of the plane shell, and all the way between it is firmly connected to a cartilage. In the middle of the length of the cardo there is placed another short, black, and very strong cardo.

It is easy to see, from hence, to what is owing that remarkably strong power, which this creature has of shutting and opening its shell; and it is very possible, that by means of so strong an apparatus of tendons or ligaments as it has in this part, it may be able to move the plane shell in so swift and regular, as well as forcible and easy a manner, that it may use it in moving from place to place; and possibly it may make a sort of wing of it, to beat against the water, as the pinion of a bird does against the air; and what the antients have so frequently said of its moving about in a very swift manner, from place to place, may be true, though we have been wanting in later observations to see it.

When the two shells are opened, the following particulars offer themselves to the view. First, the mouth: this is covered with a sort of membranous hood, as in the oister; it does not stand on the center of the head, but toward the right hand, and the covering is only an elongation of the branchiæ, or gills of the fish: these are of a membranous nature, and surround the whole body from the mouth to the anus, which stands toward the left hand from the mouth, where they are connected again.

That branchia of the exterior pair, to which the flat or plane shell adheres, is fixed in its center to an immensely strong muscle, which grows from the shell, and is fixed into the body of the fish at right angles: this branchia is fixed to the upper limb of that muscle, and the other branchia is, in like manner, connected to the lower limb of the same strong muscle. These two exterior, or spurious branchiæ, from this muscle to a considerable extent, are formed only of a thin and pellucid membrane, and being carried to the middle of the valves on each side, they are there fixed down in such a manner, that they cannot be removed by any means, without injuring or destroying them.

The use of these is to defend the body of the animal from the injuries of the water, and other substances let in with it, on the opening of the shell. From the place of this adhesion there is propagated a strong and thick muscle, of a truly wonderful structure; this is a sort of limb, or verge to the animal. It is contracted inward when the animal is dead, but while it is alive it is expanded, at the creature's pleasure, a great way out beyond the edges of the shell, and is jagged, and variegated with lines and streaks, in an amazing and elegant manner.

The use of this part seems easily guessed, it being, when expanded out at the mouth of the shell, a sort of net, for the catching whatever the creature chuses to feed upon. It is, at the pleasure of the animal, either laid flat on the surface of the mud or rock, or arched into a part of a circle: when in any of these positions, any thing comes in its way which is proper food for the creature, it immediately gathers up like a net round about it, and withdrawing itself into the shell, takes in the prey with it. In this case, the use of its being cut or fringed, is also plainly seen; for it can, by means of this structure, let out the water taken in with the prey through the jags, and yet retain the prey itself. Philos. Trans. N° 229. p. 567.

The use of this admirable muscle, is not only the serving as a net for the taking the food, and afterwards as a strainer for the separating the water from it, but its muscular force is so great, that it also serves as a weapon of death to the little animal it has seized, by compressing it to pieces if necessary, at least by squeezing it till no life remains. This is a very necessary article in the preying of an animal, which can neither follow or resist an animal in motion; but this is not all. When the prey is brought into the shell, it might there remain, where first laid down, without being of any use to the *scallop*, who cannot turn about her mouth to come to it: in this case the same wonderful muscle, by its undulatory motion, serves to convey the prey to a part of the shell nearer the mouth of the animal; and when there, taking it up between the jags of the fringe, it holds it to the opening of the mouth; in this last office serving in the place of a hand. These are the many and necessary uses of this part.

But to come to the branchiæ, or gills, properly so called. The true branchiæ are four in number; they are of a yellowish colour, and are fringed in a very elegant manner: these every way surround the great central muscle, and serve as a covering to the uterus of the animal, or its ovary; certainly, however, to the parts of generation, by whatever name they may be called.

The lower part of the body of the *scallop* is yellow, and its upper part white, and near its mouth there is very plainly to be discovered a process with a double aperture. It seems probable, from all observation, that the *scallop* is an hermaphrodite animal, and contains the parts of generation of both sexes in each individual; and it appears that the female part of generation is, on occasion, pushed out from one of these apertures, and the penis, or male part, from the other.

The mouth of the *scallop* is furnished with reddish lips, resembling the branchiæ, or gills, in their structure, but very short and small; and near the hinge there are two large circular cavities, resembling the eyes of the turbot. Near the head there is a large mass of blackish matter toward the left hand, and under that, or rather behind it, is situated the creature's heart. The pericardium is pellucid, and is of so fine a structure, that the heart is easily seen through it: it is of a reddish colour, and its aorta, or large artery, is divided into a great number of branches, which are sent every way round to the gills.

It is some doubt, however, whether this their membrane, before described, serves alone in the capacity of a pericardium; or whether all this black matter, that lies about it in a sort of rhombic form, does not also, in some degree, supply that office. The lower part of this gives place to the urinary bladder, and the strait gut arises from the base of this black substance, and is thence carried strait over the pericardium; whence it runs on to the branchiæ, and is at length affixed to the great central muscle.

This central muscle is of a rounded figure, very smooth, and white, and even in the greater part of its bulk, where it is connected to the shell; but on the left it is divided, and forms another white and lacerated muscle, which runs along a part of the shell, and strengthens the connection of the body of the fish with this part of the plane valve. Philos. Trans. N° 229. p. 569.

SCALMUS, among the Romans, a block or round piece of wood in a boat, to which the oars were tied with a thong of leather called *strappus*. See the article STRAPPUS.

Scalmus was also used to denote the boat, a part being taken for the whole. *Pitisc.* in voc.

SCALPRA *dentalia*, instruments used by the surgeons to take off those black, livid, or yellow crusts, which infest the teeth, and not only loosen and destroy them, but taint the breath.

According to the varieties of the occasion, the surgeon has these instruments of various shapes and sizes; some are pointed, and narrow at the end, others are broader pointed, and have edges, others are hooked, or falciform, but these are usually, for convenience of carriage, all adapted to one handle.

The manner of using them is to begin near the gums, supporting the blade with the left hand, and scraping all along the tooth, till the crust is taken off, taking care not to wound the gums, or displace the teeth. *Heister's* Surgery, p. 456.

SCAMMA, Σκαμμα, among the Greeks, the mark in leaping, or throwing quoits; so called, from its being made by digging up the earth. *Potter*, Tom. I. p. 442.

SCAMMATHA, in the Jewish customs, a kind of excommunication, and the most terrible of all in use among that people. See the article NIDDUI.

SCAMMONY (*Cycl.*)—SCAMMONIA *Monspeliaca*, *Montpelier scammony*, a name given by some botanical writers to a species of periploca, distinguished by Mr. Tournefort by the name of *periploca Monspeliaca foliis rotundioribus.*

SCAMPIUSA, in botany, a name used by Myrepsus and others for a plant, which they greatly recommend in the itch, and other cutaneous disorders.

Fuchsius confesses himself at a loss to guess what plant was meant by this name; but a little knowledge of the customs of the later Greeks, in adopting the Roman names for things, would have explained this to him. We find, by familiar instances without number, that in the words they adopted from the Latin, they usually changed the *o* into *u*, and the Roman *b* into *mp*. If we look upon the word *scampiusa* in this light, suppose it formed from a Roman word,

word, as most of the names of plants at that time were, and change the *u* into an *o*, and the *mp* into *b*, we immediately bring back the word to *scabiosa*; a very well known Latin word, and the name of a plant possessed of the same virtues they have given to the *scampiusa*.

They sometimes also wrote this *campiusa*, without the initial *s*; but this cannot appear wonderful, when we recollect that the *milax* was in the same manner *smilax*, and the *smaragdus* was written *maragdus*, even by the antient Greeks themselves.

SCANDIACA, in botany, a name given by some authors to the white flowered *lamium*, called archangel by others. *C. Bauhin*, Pin. 155. See LAMIUM.

SCANDULÆ, in antient house building, shingles, or flat pieces of wood, used by the Romans instead of tiles to cover houses. This, according to Cornelius Nepos, was the only covering used in Rome till the war with Pyrrhus, or 470th year of the city. *Pitisc.* in voc.

SCANDULARII, among the Romans, mechanics who prepared the *scandulæ* used in covering houses, who were exempted from all public services. See SCANDULÆ.

SCANDYX, *venus comb*, in botany, the name of a genus of plants of the umbelliferous kind, the characters of which are these. The flower is of the rosaceous kind, consisting of several petals, which are arranged in a circular order on a cup, which afterwards becomes a fruit composed of two oblong bodies, resembling needles, and containing the seeds. The species of *scandyx*, enumerated by Mr. Tournefort, are these. 1. The common *scandyx* with rostrated seeds. 2. The larger Cretic *scandyx*. And 3. the smaller Cretic *scandyx*. *Tourn.* Inst. p. 326.

SCANELLO, in the Italian music, is used for the bridge in violins and other instruments. It is the same with *ponticello* and *magas*. See the articles BRIDGE and MAGAS.

SCANSOR, in ichthyology, a name given by Gesner to the fish called by the generality of writers *lupus piscis*. See the article LUPUS.

SCANTON, a word used by some to express the fetid smell of wine.

SCAPE *goat*, in the Jewish antiquities, the goat which was set at liberty on the day of solemn expiation. For the ceremonies on this occasion, see Levit. xvi. 5, 6, &c.

Some say that a piece of scarlet cloth, in form of a tongue, was tied on the forehead of the *scape goat*. *Hofm.* Lex. univ. in voc. *Lingua*.

Many have been the disputes among the interpreters, concerning the meaning of the word *scape goat*, or rather of *azazel*, for which *scape goat* is put in our version of the Bible.

Spencer is of opinion that *azazel* is a proper name, signifying the devil, or evil dæmon. See his reasons in his Book de leg. Hebr. ritual. Dissert. viii. Among other things he observes, that the antient Jews used to substitute the name *samaël* for *azazel*, and many of them have ventured to affirm, that at the feast of expiation they were obliged to offer a gift to *samaël* to obtain his favour. Thus also the *goat*, sent into the wilderness to *azazel*, was understood to be a gift or oblation. Some Christians have been of the same opinion. But Spencer thinks that the genuine reasons of the ceremony were, 1. That the *goat* loaded with the sins of the people, and sent to *azazel*, might be a symbolical representation of the miserable condition of sinners. 2. God sent the *goat* thus loaded to the evil dæmons, to shew that they were impure, thereby to deter the people from any conversation or familiarity with them. 3. That the *goat* sent to *azazel* sufficiently expiating all evils, the Israëlites might the more willingly abstain from the expiatory sacrifices of the Gentiles.

SCAPHA, in anatomy, is used to express the external circumference of the ear.

It is in surgery used to express a bandage for the head. See the article BANDAGE.

SCAPHEPHORI, Σκαφηφοροι, among the Athenians, an appellation given to the strangers residing among them, because they were obliged, at the festival Panathenæ, to carry little ships, called *scaphæ*, σκαφαι, which were a sign of their foreign extraction. *Potter*, Archæol. Græc. Tom. I. p. 56.

SCAPHIUM, among the Romans, a cup of an oblong form, somewhat resembling that of a boat, whence also it had its name. *Pitisc.* in voc.

Scaphium likewise signifies a kind of dial, which, beside the hours, shewed also the solstices and æquinoxes. *Pitisc.* Lex. Antiq. in voc.

SCAPHOIDES *os*, (*Cycl.*) in anatomy, the first bone of the first row in the carpus. It has its name from the Greek σκαφη, a boat, is sometimes called *os naviculare* in Latin for the same reason, as supposed to resemble a little boat. It has a convex side next the radius, by which it is articulated with the basis of that bone, and with a tubercle, which is one of the four eminences on the concave side of the carpus. Toward the thumb it has two half sides, one large one for the os trapezium, and the other a small one for the os trapezoides. It has likewise a hollow side for the os magnum, and a small semilunar side for the os lunare. Its inner and outer surfaces are rough. *Winslow*'s Anatomy, p. 83.

SCAPHOIDES *tarsi*. This bone, which is called also *naviculare*, from its resemblance to a small flat boat, lies before the astragalus. It has two cartilaginous sides, an oval circumference, and a tuberosity. Its thickness is inconsiderable, when compared with its other dimensions, and it lies as it were on its side, before the astragalus. The concave side is posterior, and is articulated with the anterior convex side of the astragalus. The anterior convex side is divided by two small lines into three planes, for the articulation of the three ossa cuneiformia. The circumference forms an oval, which contracts by small degrees, and terminates in an obtuse point: one side of this circumference is more convex and rough than the other, and the inequalities in it serve for the insertion of ligaments. The points of the oval ends in a tuberosity, marked with a muscular impression. In the natural situation of this bone, the most convex side is uppermost, the other lowest, and the tuberosity turned inward and downward. By this situation, and the difference of the sides, it is easy to distinguish the os naviculare of the right foot from that of the left. The smaller, or inferior convexity of the circumference has, near the tuberosity, a superficial notch, and on the opposite side a small cartilaginous surface, and a small tubercle for its articulation with the os cuboides, &c. for the insertion of ligaments. *Winslow*'s Anatomy, p. 98.

SCAPULA (*Cycl.*)—This is a large bone, situated laterally at the upper and posterior part of the thorax, from about the first rib down to the seventh. The neck of the *scapula* is the largest of its three angles, and ought more justly to be called a head with a very short neck, and a superficial, or glenoide cavity in the top of it, which is lined with a cartilage, and of an oval figure, but pointed at the upper part, and rounded at the lower; and is much deeper in the natural state, than when viewed in the sceleton. In the natural situation of the *scapula* this cavity is turned obliquely forward, and not directly outward. Between the edge of this cavity and the contracted part, which is the true neck, some inequalities are observable, which are the remains of the symphysis of ossification. Above and below the glenoide cavity are two small rough marks, or impressions, the lowest of which extends itself a little over the neighbouring costa. These may be termed the muscular impressions of the neck of the *scapula*. In the neck, spine, basis, inferior costa, and coracoide process of the *scapula*, there is a diploe; the rest of the bone is transparent, thin, and almost without any middle cellular substance. The *scapula* is articulated with the clavicle by the acromion, and with the os humeri by the glenoide cavity: it is likewise joined to the trunk by a fleshy symphysis, or syssarcosis. It serves to facilitate the motions of the arm, to give insertion to a great many muscles, and as a shield to defend the back parts of the thorax. *Winslow*'s Anatomy, p. 73.

Fracture of the SCAPULA. The *scapula* is usually fractured either near its acromion, or head, where it joins the clavicle, or in some more distant part. If the fracture happens in the process of the acromion, the reduction will be easily made, by lifting up the arm to relax the deltoide muscle, and pushing the arm evenly upwards, making the fractured parts meet together with the fingers: but notwithstanding their reduction is so easy, they easily slip away again from any slight cause, and so are difficultly agglutinated. They are in particular very easily separated by the weight and motion of the arm, and by the contraction of the deltoide muscle; insomuch that there is scarce ever an instance of a fractured acromion being so perfectly cured, as to admit afterwards of a free motion of the arm upwards: all means must, however, be used to endeavour to keep the replaced bones in their proper situation. A compress, wet with spirit of wine, is to be applied to the fracture, a ball is to be put under the arm-pit to support it; the whole is to be bound up with the bandage commonly called *spica*, and the arm is to be suspended in a sash or sling hung about the neck. But if the neck of the *scapula*, which lies under the acromion, or its acetabulum, should be fractured, which is a case that indeed very seldom happens, and when it does is very difficult to discover, it is a hundred to one but from the vicinity of the articulation, the tendons, muscles, ligaments, nerves, and large veins and arteries, there will follow a stiffness and loss of motion in the joint; great inflammation is also to be expected, and abscesses with the worst symptoms, and sometimes death itself.

SCAPULAM *antrorsum agens*, in anatomy, a name given by Vesalius, and some of his followers, to the muscle generally known under the name of the *serratus anticus*. He has also, in another part of his work, called it *primus scapulam moventium*. Riolanus has called it the *serratus minor*, and several other authors the *secundus scapulæ*. See the article SERRATUS.

SCAPULAM *attollens*, in anatomy, a name given by Spigelius to a muscle, which he also calls *musculus patientiæ*. It is the *levator scapulæ* of Albinus and Cowper.

SCAPULAM *moventium secundus*, in anatomy, the name given by Vesalius to a muscle, called by Winslow and some others the

the *trapezia*, and by Albinus the *cucullaris*. Cowper calls it the *trapezius*, or *cucullaris*. See TRAPEZIUS.

SCAPUS, among botanists, a peculiar kind of stalk, which supports the parts of fructification of a plant. It does not grow from any part of the main stalk, but rises immediately from the root. See STALK.

SCAR *crow*, in zoology, the name of a bird of the *larus*, or sea gull kind, called by authors *larus niger*, or the black gull, and by the Germans *brandvogel* and *meyvogel*. It is a very long winged bird, and is all over black, and of the size of the common blackbird. Its legs are short and red. It is common about the sea coasts, and feeds on insects. It is a well tasted bird. *Ray's* Ornithol. p. 296.

SCARABÆUS, the *beetle*. This is an extremely numerous genus of insects; and in order to have a distinct idea of the differences of the species, they are arranged by Lister into a sort of method. The first general distinction is into those which live on land, and those which live in the water; of each of which there is a very great number. Those *beetles* which live on land have some of them antennæ laminated at the end, others have them sharp pointed. The outer wings, or cases of the wings, in some are perfect, in others they seem mutilated. Some have the antennæ inserted into a sort of promuscis. These were called by the antients *gurguliones*, and in some there is only one juncture in this, in the middle, in others several near the end. Some have a sharp pointed instrument at their head; these are called *cimices*. See the article CIMEX.

Of the water *beetles* there are two principal kinds, one sort living in salt water, the other in fresh.

Of those *beetles*, the extremity of whose antennæ are formed like a comb, there are ten species mentioned by Mr. Ray. 1. The great reddish *beetle* with the tail bending downwards, known among us under the name of the *chaffer*. This is too well known to need a description; it is common among trees and bushes at the end of May, and seems particularly fond of the maple. 2. The greyish yellow woolly *beetle*. This seems nearly allied to the former species, but is but about half as big. These are very common in the southern parts of England in the month of June; they fly about elms in vast swarms; they are very rare in the northern counties. 3. The greenish black *beetle* with reddish brown cases of the wings. This is of the size of a horse bean, and is found among rose trees in May. 4. The great purplish black *beetle* with serrated legs. This is one of our largest *beetles*, and is very common on heaths, and in other places, in the month of March; it flies about in the evening, and makes a great noise; it is usually infested with a great number of yellow lice, and is thence called the *lousy beetle*. 5. The large black *beetle* with two yellow undulated fasciæ on the cases of the wings. This is sometimes found without the fasciæ; it sometimes flies, but rarely. It is found about human dung, and probably feeds on it, for it has always a very strong scent of it. 6. The green *beetle* with red cases for the wings. This is about the size of a horse bean, and is found in woods in the month of June. 7. The small *beetle*, called the *lady bird*. 8. The *lady bird* with only two large black spots, one on each of the cases of the wings. This is common among bushes in the beginning of June. 9. The yellow *beetle* with black spots. This is much smaller than the lady bird; its colour is a pale yellow, or lemon colour, and it has four black spots, of an oblong square figure, on the cases of the wings. 10. The reddish *beetle* with two spots on the shoulders, and seven white marks on each of the cases of the wings. This is about the size of the common lady bird, and is found in June near rivers, among the rushes, and in cyperus grasses. *Ray's* Hist. Insect. p. 384.

Of those *beetles* which have antennæ terminating in slender points, there are a great number of species, which may be subdivided into some other general classes: some of them have whole and perfect cases to their wings, and have long horns; these are by some called *capricorn beetles*; of these there are several species. See the article CAPRICORN.

Some *beetles* are covered with a very hard crust, and have scarce any wings underneath it. These are generally very slow creepers, and of these we have in England three species. 1. The short purplish black *beetle* with gibbous shoulders. This seems to be the same with the *cat beetle*, or *scarabæus feliformis* of Mouffet, and others. This is not unfrequently found on heaths in March, and at that time is often found in coitu. The male is considerably smaller than the female. This creature feeds on the yellow gallium, and when fatigued will cast out at its mouth a yellowish liquor, which is of a pungent taste like pepper. 2. The slow stinking black *beetle*, called the *blatta fœtida* by Pliny and others. This is of a deep dusky black colour, not at all glossy or shining. This is common in cellars, and other damp places, in the month of April. 3. The great purplish *beetle* with a cast of green. This is common in gardens, and in April is always infested with a great number of lice.

Some *beetles* which have wings very rarely use them, but run very swiftly along the ground; of these we have two species common among us. 1. The black *beetle* with sulcated wings. This is a very common insect, and is frequent in pathways in April. 2. The black *beetle* with striated wings, and with yellow legs and horns. This also is common in pathways in summer.

All these *beetles* have the antennæ laminated at the ends. Of the other kind, which have them go off to a slender and taper point, there are also many kinds: of these some have only short cases for their wings, as if they had been cut off near the root. The general characters of this class of *beetles* are, that they have oblong and slender bodies, and have two appendages forming a kind of fork at the tail. Of this kind are the common earwig, or forficula, and the staphylinus, which is a large and long black *beetle*, with a sharp fork at its tail, and with a naked body. It is of a deep and dusky black, not at all glossy; it has very large yellow wings, folded under the small thecæ on the back; it turns up its tail in a threatning posture when attempted to be caught, and throws out a sort of white bladders at it; it runs very nimbly, and is a very voracious creature, feeding on other *beetles*, or on any insects it can catch.

Some *beetles* are all over soft, and have no membranaceous wings. The bodies of these *beetles* seem covered with a crustaceous substance, but it is soft, and yields to the pressure of the finger like a bladder; these all eat herbaceous or vegetable food; we have two species of them. 1. The oil *beetle*, a bluish black shining *beetle*, called *proscarabæus* by Mouffet. This is found in meadows in great abundance, and feeds on the leaves of some of the species of ranunculus. 2. The short legged black smooth *beetle*. This has scarce any antennæ, and when tired, rolls itself up into a round ball. This is found in May feeding on the aperine, or common cleavers; but Lister suspects whether this be not a worm state of some *beetle*, rather than a perfect *beetle*.

Some *beetles* have long heads, shaped like the trunks of other insects, and in these the horns are lodged: these were called by the antients *gurguliones*. *Ray's* Hist. Insect. p. 391. See the article GURGULIO.

Some *beetles* have a forceps at the head, indented on each side in the manner of a saw. Of this kind we have only one known species in England; this is the green *beetle* with ten white spots on the cases of the wings. This is found in June in the northern parts of England. It is a very voracious animal, destroying great numbers of other insects, particularly caterpillars.

Some *beetles* have a very remarkable property of leaping, and this of a very peculiar kind; for they do not leap, like other insects, by means of their hinder legs, but by means of their breast. There are some general marks by which this genus of *beetles* may be distinguished from others; these are, 1. they are always of an oblong and flatted figure. 2. Their head is always joined in a very nice manner to the shoulders. 3. Their legs are extremely short and slender.

Of this kind of *beetles* we have in England only two known species. 1. The chesnut coloured leaping *beetle*. This is found frequently in corn-fields, and elsewhere. 2. The greenish black *beetle* with horns pectinated on one side. This is a scarce species, but is found in dry places in March. *Ray's* Hist. Insect. p. 387.

SCARABÆUS, in ichthyology, a name given by Gaza to that species of *sparus*, which is called by others the *cantharus*. It is distinguished by Artedi, by the name of the silver eyed *sparus* with yellow longitudinal and parallel lines on the sides. See the article SPARUS.

SCARABÆUS *tardipes*, the *slow beetle*. We have a very singular account of the longevity of this animal, and that without food, given by Mr. Baker from his own observation. In the year 1737 he found several *beetles* of this kind plunging themselves in the mud at the bottom of an old cistern; these were about an inch in length, and of a rusty black colour, and had long jointed antennæ: they had no wings, but only a thick shell, covering the whole body, and divided along the middle with a fissure, resembling the meeting of the two case wings in other *beetles*; the tail turned up a little, and the legs were long, but moved slowly. Mr. Baker chusing one of the largest of these, threw it into a cup of spirit of wine, in a little time it appeared to be dead, and was shut up in a small box, and laid by, but some months after it was found alive and well: it was then plunged again into spirits of wine, and left a much longer time; and after being taken out as dead, and put in the same box again for some time, when it was found again come to life. It had now twice escaped from being plunged in spirits, and lived three months shut up without any sustenance. After this the *beetle* was kept a month or two without sustenance under a glass, and at the end of this time again put into spirit of wine, and left there a whole night; after this, however, it again recovered, and seemed the next day as well as before. He lived, in the whole, two years and an half, without any visible food or drink. Several things were at times offered him by way of food, as bread, fruits, &c. and water set in his way, but he never touched either. It seems very probable that this creature received a sufficient nourishment from the particles floating in the air; and it is very possible that lizards, snakes, &c. when they live so long without any visible food, are supplied in the same man-

manner, though at other times they are capable of digesting more solid matters; as doubtless was also the case with the *beetle*, when in its own natural state. This is an instance of a creature's subsisting without visible food, longer than we have any other account of any kind; but it is possible, that though the larger animals cannot long subsist without supplies of solid food, yet many insects may find nourishment enough for their tender bodies in the particles floating in the air, though we want observations for proof of it.

While kept under the glass it did not walk about much, but usually placed its nose close against one edge of it for the benefit of the air. It was of an agreeable aromatic smell, and when touched communicated its scent to the fingers, which did not go off in a long time. Its smell is stronger in winter than in summer. This creature not only bears the plunging in spirit of wine much longer than any other animal, but it bears the exhausted receiver of an air pump without any injury or uneasiness. It has been kept under it half an hour, and would walk about without any concern; only when the air was let in it appeared startled, and drew up its legs for about a minute.

We know that the Ægyptians had a very high veneration for the *beetle*; this appears not only by the account historians give of its being one of their deities, but by the many images of it we find among their antiquities. As these were a wise and learned people, we cannot suppose they would, without some reason, pay so much regard to so contemptible an animal as this appears to be; and it is very possible they might have discovered this property of its living in this manner without food, and thence esteem it a symbol of the deity. It is not known how long Mr. Baker's *beetle* would have lived in this manner with him, for it at length got away, while a careless servant took up the glass to wipe it. Philos. Trans. N° 457. p. 447.

SCARABÆUS *vorax*, the *cankerworm*. This last term is used in the translation of our Bibles to signify a very destructive insect, of the nature of the locust, and usually mentioned as its companion. The septuagint gives it the name Βρῦχος, *bruchus*, a name signifying an animal which makes a great noise, as this insect does both in eating and in flying. We generally understand by this word a reptile, but it certainly means no other than that sort of *beetle*, which we call the *cockchaffer*, or *dor*; a flying insect, very remarkable for the humming noise it makes with its wings when in motion, and which, when it is found in swarms sitting upon the hedges, makes a continual noise in eating, like the sawing of wood. This creature deserves very well to be placed with the locust, as a destroyer of the fruits of the earth. Our own experience in Norfolk has given a very late proof of this; and the histories of Ireland shew that this creature has, in that kingdom, devoured every green leaf from the trees, for whole tracks of land at a time. That we have a wrong translation of the word *bruchus* in *cankerworm*, is evident even from the scriptures themselves; for the prophet Nathan expresly says that it is a fly, and has wings, which cannot agree with any thing of the nature of what we understand by the word worm, which always signifies with us a reptile, or a creeping animal. This prophet has indeed described them so well, that it is wonderful that so obvious a thing should not have been observed by the commentators. He says they spoil, and then flee away; they camp in the hedges in the day, and when the sun ariseth they flee away, and their place is not known where they are. That is, they then retire again to the hedges, and hide themselves among the trees, where they lie quiet and concealed till the sun sets again. It is plain, by comparing these words with the common animal here mentioned, that the *bruchus* of the Old Testament is the same with our *cockchaffer*, and that the prophet has given us the natural history of the animal he describes in this short account.

In another part of the Old Testament, the same word *bruchus* is translated *locust*, or *beetle*; and this explains the rationale of that odd clause in the Jewish law, where Moses tells the Israelites, these may ye eat of: every flying creeping thing that goeth upon all four, which have legs above their feet to leap withal upon the earth; even these of them ye may eat: the locust after his kind, and the bald locust after his kind, and the *beetle* after his kind, and the grashopper after his kind.

It has appeared very strange to many, that here among the pure and clean foods, the *beetle*, and such other dry and nasty reptiles, should be recommended as wholesome food for man; but there appears reason on the side of this when thoroughly considered. It is very evident that neither the Jews, nor any other people, would eat such insects as these, while any thing better was to be had; but as they lived in a country often visited by locusts and these *cockchaffers*, which might at some time eat up all the fruits of the earth, then in the want of these the prophet tells them they might eat up the devourers themselves, and yet be clean. So also it appears that we are to understand what we are told of St. John the Baptist, that he fed on locusts and wild honey; for it was in the desert that he eat these, where no other food was to be had.

The poor people of Ireland have taught us, that the prophet advised his people to a wholesome food in this text; for some years ago, when the county of Gallway, and other neighbouring parts, were so infested with this vermin, that the whole face of the country was destroyed by them, and the trees stripped of their leaves and fruits, as much as in the depth of winter; the poor people wanting other food, eat the vermin themselves that had done the mischief; and the *cockchaffers*, which are doubtless what is meant by Moses under the name of the *beetle*, as they are truly of the *beetle* kind, were found to be a very good and wholesome food.

It is very probable also that this kind of *beetle*, so famous for devouring the fruits of the earth, is that kind to which the Ægyptians paid divine honours, and for which they had such high veneration, that they frequently engraved its figure on their obelisks; though the antiquaries give a very different account of it, supposing that the beetle was held sacred by them, as being an hieroglyphical representation of the sun. This seems a very forced conjecture; whereas nothing can be supposed more natural, than that a nation, addicted to polytheism, as the Ægyptians were, and in a country frequently suffering great mischief and scarcity from swarms of devouring insects, should, from a strong sense and fear of evil to come, give sacred worship to the visible authors of their sufferings, in hopes to render them more propitious for the future. The same Ægyptians, we very well know, worshipped the other great destroyer of their country, the crocodile; and the Romans, a much more civilized people, built a temple to the disease which raged most among them, the fever.

The ignorant people among the Irish, when the vast swarms of these *beetles* first appeared among them, were of the same turn, and rather reverenced than destroyed them, saying that they were the ghosts of their dead friends killed at the battle of Agrhim, who were come in this form to pester and annoy their heretical enemies, the English protestants. They even thought that the English families suffered more by them than the Irish; but this was only because the grounds of the former were better improved, and the creatures found plenty of better food there. Philos. Transact. N° 234.

SCARBOROUGH *water*. The water of this medicinal spring has been the subject of great contests and disputes among the physical people; all allowing it considerable virtues, but some attributing them to one ingredient, others to another. Dr. Witty alledges that its material principles are alum, nitre, and vitriol of iron; but though this author declares, that these principles are all to be separated out of it, Dr. Tonstall, on the other hand, affirms that it has no vitriol of iron in it, but a stone powder and a clay, leaving sand at the bottom of the vessel; and therefore that it is apt to breed the stone, and is bad in the gout, jaundice, and all other diseases where indurations of the parts, or stony concretions in the body, are the cause; and this author seems to speak very experimentally, when he alledges that he never had any symptoms of the stone till he drank the *Scarborough water*, but acquired that disease during the course of it.

Alum stone dissolved in water is always found to yield a purple tincture with galls, and therefore the colouring an infusion of this or other vegetable substances by the *Scarborough water*, which is by all allowed to contain this stone, is no proof of any vitriol of iron being contained in it; other than such a small portion of it, as is always found in this alum stone. All waters, which have dissolved iron, will yield vitriol as a salt from that metal on evaporation. The cliffs about *Scarborough* yield abundance of salt in shoots and effervescences, plainly owing to the *waters* of the spring; yet all these are nitro-aluminous, none of them at all vitriolic. If the *Scarborough water* is set by for some days, after it is taken fresh from the spring, it precipitates a sediment; which being examined, is found not to be of a ferrugineous nature, but a mere glebe of alum.

Upon the whole, the virtues of alum and vitriol are so far different, that it must be easy to see which of the two salts the *water* partakes most of, by its virtues; but as to the stony matter, which the one of these disputants calls an insipid clay, and the other a sandy stone, it is no other than spar, which is contained in all water; and which has been in general so far from being accused of breeding the stone in the bladder, that the general consent of mankind has seemed to esteem it a cure for that disorder. The spar, in the form of the lapis judaicus and ostracites, and the very waters which are so impregnated with it, as to encrust every thing with it that is put into them, are given for the cure of this disease. Philos. Trans. N° 85.

SCARFED, in the sea carpenters language, is the same as pierced, or fastened or joined in: thus they say the stem of a ship is *scarfed* into her keel. They also imply by it, that the two pieces are shaped away slanting, so as to join with one another close and even; which they call *wood and wood*.

SCARIFICATION *of the eye*. See the article EYE.

SCARLATINA *febris*, the *scarlet fever*, in medicine, the name of an eruptive *fever* usually attacking young persons, and not attended with any great danger. When it is moderate in degree, it may be left to nature alone, and will go off very well without the assistance of medicines, only observing a good regimen; but if it be more violent, it is to be treated with more care: the patient is to be kept warm in bed, and to be made to drink large quantities of warm diluting liquors, acidulated either with lemon juice, or spirit of sulphur or vitriol, and draughts of the attemperating and diluting medicines are to be given every four or six hours, and by the attemperating and gently diaphoretic powder; but during the course of the cure all hot things are to be carefully avoided, as well in food as medicine, for every thing of this kind renders the disease worse, when treated in the proper manner. The *scarlet* spots, after a few days, dry off, and the skin scales away, and after this the patient usually is soon well. At this time two or three doses of some gentle purge are to be given; and if the weather be bad, the patient is to be confined to his chamber for some days afterward, that the transpiration may be free and uninterrupted; by this means, the worst kinds of this *fever* go well off.

But when this caution is neglected, it is very common to find the patient fall into a swelling of the belly after about three weeks, and sometimes into an anasarca; sometimes attended with a fever, sometimes without one, and often with tumors of the glands, and many other dangerous disorders. The urine, in these cases, becomes brown and turbid, and many are lost in this manner. But as this new disease, as it is usually called, though it is in reality no other than another period of the *scarlet fever*, owes its whole origin to the morbific matter which caused the first appearance of that, being in part retained in the body, the best method of cure is by those remedies which are able to carry those humors out of the body. Gentle purges are to be given at short intervals, and the way nature indicates is to be carefully followed, by giving diuretics in the intermediate days; for the brown turbid urine, voided naturally in this case, is an attempt of nature to carry off the matter that way. The best of all diuretics in this case is a tincture of salt of tartar and spiritus nitri dulcis mixed together, and taken twenty drops, or more, three times a day. In young subjects, who will not take purges in the common way, a glyster made of an infusion of sena purges them very well, and answers the purpose.

The common hot sudorifics are not to be given in these cases, for sweat is scarce to be obtained by any means in this disease; and great care is to be taken to keep the tumid parts from the cold air, otherwise the patient is often carried off at once by the chilling them. If there be a fever with this second complaint, as is usually the case, the attemperating medicines are to be given in an afternoon and evening, and draughts of gently diuretic liquors to be drank after them.

In this, and in all other eruptive *fevers*, any thing that cools the patient is of the utmost consequence, and the bed is not to be new made, nor the shirt changed by any means, during the course of the distemper. Immoderate heat, on the other hand, is almost as bad, and the middle regimen is the only proper one to be observed. The patient lying quiet, and being kept in an equal and moderate heat, in all cases of eruptive *fevers*, as well as in this, the patient may be allowed, in the beginning, to walk about in his chamber, taking great care to keep out the cold, and need not be confined to his bed, so long as his strength will permit his keeping up. *Heister*'s Compend. Med. p. 83.

SCARUS, in zoology, the name of a sea fish, of which there have been several remarkable things asserted by the antients, some with and some without any foundation; as that it ruminates, or chews the cud like our oxen, *&c.* This Aristotle, Pliny, Oppian, and others affirm, but none of them of their own personal knowledge; they seem to have had it by hearsay, or else as authors often do, to have taken it from one another; for the thing is not true in fact.

It has been said also to be the only fish which feeds on herbs; and it is so far true that it does feed on them, and that few other fish, but not that no other feed in the same manner. It has been reported also that this is the only fish that sleeps. Gesner would persuade us, that not only this, but many other fish, also sleep. But this does not seem to be the fact; for this race of animals have no eye-brows, nor any membrane to close and cover their eyes with, as other creatures have, which nature has allotted sleep to. *Ray*'s Ichthyogr. p. 304.

The later naturalists have described three species of this fish, Rondeletius two, the *scarus onias*, and *scarus varius*; and Bellonius one, which is different from both these, and seems to have been the very fish the antients knew by this name.

The *scarus onias* is a sea fish, found among rocks and near the shores. Its scales are large and very thin, and its back of a blackish blue; its belly of a fine white, and is of an oblong and rounded shape; its teeth are broad, not pointed, and resemble those in the human jaws; its eyes also are large, and its head over the eyes of a fine strong and clear blue.

The *scarus varius* is of the shape and figure of the former, but its eyes and its belly are of a purple colour; its tail is of a fine clear and strong blue, and the rest of its body is of a greenish or bluish black; its scales are spotted and speckled with dusky dots; its mouth is moderately large, and its teeth broad in the upper jaw, and somewhat pointed in the under. From the head to the tail, all along the ridge of the back, there runs a row of short spines, which are connected at their bottoms by a membrane; and in the middle of the belly there are several purple spots. It is a very beautiful fish. *Rondelet.* de Pisc. lib. 5. cap. 3.

The *scarus Bellonii*, which differs from both these, and seems to be the same fish which the antients called by this name, is of a mixed bluish and red colour; its scales are broad and thin, and it has two transverse protuberances near the sides of the tail. Its body is rounded, but not very long; its teeth are strong and obtuse, and well fitted for their office, which is the tearing off the tough sea herbs from the rocks, and chewing them for food. Its mouth is but small, and it has only one fin on the back, which is prickly. Its usual size is about five or six inches in length. It is accounted a very delicate fish, but is insipid unless eaten with the guts, and all that they contain. The liver and stomach of this fish, with its contents, are cooked up by the Greeks into a very delicate dish; the epicures among them not regarding the rest of the fish. *Bellonius*, de Pisc. p. 126.

SCARY, in husbandry, a term used by the farmers for a barren land, which has a poor or thin sward, or coat of grass, upon it. *Plot*'s Oxford. p. 247.

SCATARELLO, in zoology, the name of a small bird of the ficedula kind, of a greyish brown on the back, and a pale yellow on the breast and belly. Its legs are black. It seems nearly allied to the beccifago. *Aldrovandus*, de Avibus. See the article BECCIFAGO.

SCATCH-*mouth*, in the manege, a bit-mouth, differing from a canon-mouth in this, that the canon is round, whereas a *scatch* is more upon the oval. That part of the *scatch-mouth* that joins the bit-mouth to the branch, is likewise different; a canon being stayed upon the branch by a fonceau, and a *scatch* by a chaperon, which surrounds the banquet. The effect of the *scatch-mouth* is somewhat greater than that of the canon-mouth, and keeps the mouth more in subjection. Commonly snaffles are *scatch-mouths*.

SCATEA, a word used by Paracelsus for a somewhat hard sabulous concretion in the urine.

SCAULEZ, in ichthyography, the name of a fish common on the Mediterranean shores, and called by authors ***hepsetus*** and ***anguella***. *Willughby*'s Hist. Pisc. p. 210. See the article HEPSETUS.

SCAZONE, in ichthyology, a name given by Salvian and others to the fish which we call the ***pricked dog***, or ***hound***, and the generality of authors the ***galeus spinax***. It is a species of squalus, distinguished by the roundness of the body, and the having no pinna ani. See the article SQUALUS.

SCELETON, in anatomy. See the article SKELETON, *Cycl.* and *Suppl.*

SCEMI, in botany, a name given by some authors to the *carob*, or sweet pipe tree. See the articles SILIQUA and CAROB.

SCENE (*Cycl.*)—The original *scene* for acting of plays was as simple as the representations themselves; it consisted only of a plain plat of ground, proper for the occasion, which was in some degree shaded by the neighbouring trees, whose branches were made to meet together, and their vacancies supplied with boards, sticks, and the like, to compleat the shelter; and these were sometimes covered with skins, sometimes only with the branches of other trees newly cut down, and full of leaves.

It does not appear that the antient poets were at all acquainted with the modern way of changing the *scenes*, in respect of the different parts of the play, but all was performed in the same place.

The first things represented in these new theatres were what they called *mimi*. These were a very coarse sort of poems, representing, in obscene and indecent language, the vices and indecent actions of the principal people of the time. Sophrones and Xenarchus seem to have been the first writers of this sort of comedy, and they used sometimes prose, sometimes verse, in these compositions. After the licentious things, thus represented, had given great offence to the magistracy, the poets hands were tyed up from writing at all, and the actors in these *scenes* were forbid to speak. Hence arose a new way of entertaining the spectators, which we still continue, under the name *pantomime*, the same by which they expressed it. In this all was represented in dumb shew, and the gestures and motions of the limbs were all they had to represent the actions of others by.

This sort of public diversion seems to have been in fashion in the days of Aristotle, and to have been continued long afterwards. Salmasius is of opinion that Pylades was the first who separated the pantomime and dancing from the plays,

plays, where the actors spoke. But this seems an error in that great critic, for they seem, by what histories we have left of them, to have been represented singly long before that time, Pylades living in the time of Augustus Cæsar. Poetry and dancing were early supposed to have some relation to one another; the first was called a *speaking dance*, and the latter a *dumb poem*; a name afterwards, and not till long afterwards, given to a picture. Thus they were introduced on the same *scenes*, as things naturally connected together.

SCENT. Some animal carcasses, buried with lime, though ten feet under ground, have been observed to give so strong a *scent*, as to attract dogs to the place. See LIME.

SCENT *bags*, in natural history, a name given by Tyson to those peculiar pouches, or bags, which certain animals, as the civet cat and musk animal, have for the receiving the matter of their perfume. These *bags* are common to more animals than is generally supposed, and in all have much the same qualities, the matter they contain being in most of them fœtid, and disagreeable, while contained in the *bag*, and only becoming sweet and pleasant when dried, or taken at least from the animal, and smelt in small quantities. The weasel and polecat with us have *bags* of this kind, and the famous bag, or pouch of the opossum, is of the nature of these; though it serves also to the other great purpose of receiving and sheltering the young in time of danger. It contains, like the rest, a tough and viscous matter, which ouzes out of the glands, and is of a very offensive smell while the creature lives; but as soon as it is taken out and dried, the smell changes into a fine perfume. The gland of the aper moschiferus, as Tyson calls it, is of this kind, containing a glutinous humor of a very offensive smell when fresh, but when dried, becoming sweet and perfumed as musk. Philos. Transact. N° 239. p. 125. See the article APER.

SCEPASTRA, the name of a kind of bandage for the head, described by Galen.

SCHADIDA *calli*, in botany, a name given by some authors to the plant which affords the euphorbium of the shops. *Herm.* Cat. p. 31.

SCHÆNANTH, *schænanthus*, in botany, the same with *ischæmum*. See SCÆNANTH and ISCHÆMUM.

Schænanth was much praised by the antients as a deobstruent, and promoter of the menses; but at present it is only kept as an ingredient in some officinal compositions.

SCHÆNICLOS, in zoology, the name of a bird, which, by the description of Bellonius, seems to be the same with that called by the French *alouëtte de mer*, the *sea lark*, and by us the *stint*. *Aldrovand.* lib. 20. cap. 56.

SCHAFFILT, in zoology, the name of a very small owl, not larger than a thrush, called *noctua minor* by authors.

Its eyes are very bright, and of a yellow colour; its ears very large; its feet are feathered to the toes, and the soles of its feet are yellow. It is caught in the woods in Germany. *Ray*'s Ornitholog. p. 69.

SCHAKARILLA, or SCHACARILLA, in the materia medica, a name given by some authors to the medicinal bark called *cortex thuris*, and *cortex elutherii* by others. *Montani* Exot. p. 8.

SCHAPHAN, in Jewish antiquity, the name of an animal declared unclean by the law of Moses [b]. Interpreters do not agree in their explanations of this word.—[b Levit. xi. 5.] See the article CHOEROGRILLUS.

SCHASIS, a word used by some of the writers in surgery to express scarification.

SCHEAT, or, as it is sometimes written, SCHEAD, or *sheart*, a name given by many to the jentling, a fish of the chub kind, caught in the Danube, and most of the larger rivers of Germany, and called by Gesner and Aldrovand *capito cæruleus*. *Willughby*'s Hist. Pisc. p. 256. See JENTLING.

This is the *glanus* of Pliny, and the other old Roman authors, and is distinguished by Artedi by the name of the *silurus* with four beards near the mouth. This is its character in which it differs from the *lake*, another fish of this kind; which, though a genuine species of *silurus*, has only one beard.

SCHELLENT, in zoology, the name of a species of duck, found about the sea coasts, of the size of the common duck, and differing from the *capo rosso* in this, that it is twice as large, and the eyes have yellow iris's; though agreeing with it in the colour of the bead, which is of a reddish brown. Its neck is grey, and its back is of a blackish grey; its throat, breast and belly white, but near the anus there is a transverse brown line. The long feathers of the wings are black and white, and the tail of a blackish grey. *Aldrovand*, de Avib. p. 223.

SCHELLEY, in zoology, a name given in some counties of England to the fish known among authors by the name of *ferra*. *Willughby*'s Hist. Pisc. p. 184. See FERRA.

SCHEME, (*Cycl.*) *schema*, σχημα, in the antient music, is used for the varieties arising from the different positions of the tones and semitones in a consonance.

SCHETES, was formerly a term for usury; and the commons prayed that order might be taken against this horrible vice, practised by the clergy as well as the laity. Rot. Parl. 14 Rich. II. *Blount.*

SCHETIC *diseases*, a term used by the old writers in medicine to express such diseases as were not deeply rooted in the constitution, but might be easily removed.

SCHEUKZERIA, in botany, the name of a genus of plants, the characters of which are these. The perianthium is divided into six oblong, acute, reflex and expanded leaves, remaining with the fruit. There is no flower of petals. The stamina are six very short and flaccid capillary filaments. The antheræ are erect and obtuse, very long, and of a compressed figure. The germina of the pistils are three in number; they are of the size of the cup, and of an oval compressed figure; though there be no style. The stigmata are oblong, and obtuse on the upper part; they grow on the outside to the germina. The fruit consists of as many capsules as the pistil had germina; they are of a roundish figure, inflated and compressed, and each composed of two valves. The seeds are single and oblong.

The number of the germina and capsules vary, from three up to six; the three seem, however, the most natural state of the flower, and are the most frequent. *Linnæi* Gen. Plant. p. 152.

SCHILUS, in ichthyology, a name given by many to the fish called by the generality of authors *lucioperca*, or the pike fish. See LUCIOPERCA.

Artedi refers it to the genus of the *perca*, or pearch, and distinguishes it from the common pearch, by calling it the pale spotted pearch with two large teeth on each side the mouth. See the article PERCA.

SCHINELÆON, a word used by the antients to express an oil of mastich, or oil in which mastich was dissolved.

SCHINUS, in botany, the name by which Linnæus calls the genus of plants, described by Tournefort and others under the name of *molle*. The characters are these: the cup is very small, and is lightly indented in five places. The flower consists of five expanded petals. The stamina are a considerable number of oblong slender filaments. The germen of the pistil is roundish, and the fruit is a globose berry, containing a large seed of the same globose figure. This plant, in its external appearance, resembles very much the *rhus* and the *lentisk*, in the fructification, but when closely examined, is found to differ from both; from the former, in having more than five stamina, and from the latter, in the petals. *Linnæi* Gen. Pl. p. 515.

SCHIRROSIS, a name given to a disorder of the eye, arising from the violence of a long continued inflammation, when the flesh increases in bulk, and assumes a livid colour.

SCHISMA, in music. Some, as Grassineau, make this interval equal to half a comma, and say that eighteen of them are required to make a compleat tone, reckoning nine commas to a tone. But all this is inaccurate. See the article INTERVAL.

It is also used by some for the difference between the tones major and minor [c], called by others a *comma*.—[c *Descartes*, Comp. Music.] See COMMA, *Cycl.* and *Suppl.*

SCHIT-ELU, in botany, a name given by some authors to the plant, which produces the seed called *sesamum* in the shops. Hort. Mal. Vol. 9. p. 105.

SCHLEMMEN, a term used by the smalt-makers to express the substance of the smalt after fusion, when it is separated from the *eschel*; that is, a sort of grey ashes which adhere to it, and is ready for powdering for use.

SCHNOT *fish*, a name by which some call the hasela or hasler, a fresh water fish, approaching to the mullet or chub kinds, and at some seasons esteemed a very delicate dish. *Willughby*'s Hist. Pisc. p. 261. See the article HASELA.

SCHOENAS, among the antients, a land measure containing two parasangs, or sixty stadia, according to Herodote; which makes seven and an half of our miles. But Pliny computes it at five miles, or fifty stadia. *Pitisc.* in voc. See PARASANG and STADIUM, *Cycl.*

SCHOLARES, an ecclesiastic order, instituted by Innocent the third in the council of Lateran. *Hofm.* Lex. univ. in voc.

SCHOOL, (*Cycl.*) or SCHOOLING, in the manege, is used to signify the lesson and labour both of the horse and horseman.

A *school pace* or *gate* denotes the same with *ecoute*. See the article ECOUTE.

SCHRAITSER, in zoology, the name of a fish very common in the Danube, and in many things resembling our ruff, or small gilded pearch.

Its common size is about three inches in length; its tail is forked, and its back fin is supported by thirty rays or nerves, eighteen of which are rigid and prickly, and those which stand behind them soft and flexile. The upper jaw has a membrane somewhat like a lip, which hangs from it, and the coverings of the gills terminate in a spine or prickle. The membrane of the back fin is variegated with black spots, and its general colour is somewhat paler than that of the pearch. It is a very well tasted fish. *Ray*'s Ichthyography, p. 335.

SCHWALBEA, in botany, the name of a genus of plants, the characters of which are theſe. The perianthium conſiſts of one leaf, and is of a very ſingular figure, being tubular, inflated, and ſtriated on the ſurface, and terminated by an oblique mouth, lightly divided into four ſegments. The upper ſegment is ſmalleſt of all, the two ſide ones are longer, and the bottom one is longer and broader than theſe, and is emarginated. The flower conſiſts of one leaf, and is of the labiated kind. The tube is of the length of the cup, and the limb erect. The upper lip is erect, hollow, and undivided; the lower lip is of the ſame ſize, but is divided into three obtuſe and equal ſegments. The ſtamina are four capillary filaments, of the length of the flower, but two of them are a little ſhorter than the others. The antheræ are incumbent. The germen of the piſtil is round. The ſtyle is of the length and figure of the ſtamina, and is placed in the ſame ſituation. The ſtigma is thick and crooked. The ſeed is ſingle, roundiſh, and ſmall. *Linnæi* Gen. Pl. p. 291. Flor. Virgin. p. 71.

SCIADEPHORI, Σκιαδηφοροι, among the Athenians, an appellation given to the ſtranger women reſiding in Athens, becauſe they were obliged, at the feſtival Panathenæa, to carry umbrellas to defend the free women from the weather. *Potter*, Archæol. Græc. lib. 1. cap. 10. Tom. I. p. 56.

The word comes from Σκιαδεια, an umbrella, and φερω, I carry.

SCIÆNA, in the Linnæan ſyſtem of zoology, the name of a diſtinct genus of fiſhes, the characters of which are; that the opercula of the gills are ſcaly, and the back fin is bifid. Of this genus are the *umbra*, &c. *Linnæi* Syſt. Nat. p. 54. The characters of this genus, according to the Artedian ſyſtem, are theſe. The whole head, and the coverings of the gills, are ſcaly, and one of the laminæ of theſe coverings is ſerrated at the edge. The body is compreſſed and broad; the back is acute; and the teeth are only in the jaws and fauces, the palate and tongue being bare. There is only one fin on the back, but it is bifid, being ſo deeply divided at the middle, that it ſeems to make two. The tail is not forked, but even at the end. The appendices of the pylorus are ſeven or eight in number.

There are only two known ſpecies of this genus. 1. The *ſciæna* with the upper jaw longeſt, and the lower jaw bearded. This is the *ſciæna* and *umbra* of authors, and is called by Bellonius *chromis*. 2. The *ſciæna* variegated with black, and with very black belly fins. This is the *umbrino* of the Italians, and is the fiſh called *corvulus* and *coracinus* by many authors. The lines are of various lengths and breadths, and are laid obliquely on the ſides. The mouth is large, and the eyes brown. *Artedi*, Gen. Piſc. p. 29. See UMBRA and CORACINUS.

The name *ſciæna* is of Grecian origin, derived from the word Σκια, a ſhadow. The fiſh had this name from its being of a duſky or ſhadowy colour.

SCIAMACHIA, the fighting with a perſon's own ſhadow, a ſort of exerciſe preſcribed by the antient phyſicians, in which the motion of the arms, and other parts of the body, were of very great ſervice in many chronic caſes.

SCIAPODES, Σκιαποδες, a fabulous race of men, mentioned by Pliny, who had only one leg.

They were called *ſciapodes* from σκια τε ποδος, becauſe in ſummer they held up their leg, and ſheltered themſelves from the heat with the ſhadow of their foot. *Hofm.* Lex. in voc. See the article MONOCOLI.

SCIARRI, in natural hiſtory, the matter which runs down in burning torrents from the craters of Mount Ætna.

This matter, when cold and hard, is hewed and employed at Catania, and other places. It is chiefly uſed for the baſements and coinage of buildings. It probably contains mineral and metallic particles, being a ponderous, hard, grey ſtone. Philoſ. Tranſ. N° 481. p. 327, 328. See the article STONE.

Some of the *ſciarri* are coarſe, and others fine and poliſhed on the ſurface; ſome of them are black, others reddiſh, and others of the colour of iron; and many of them have coverings of pure ſulphur over the whole ſurface, or a part of it. Some very fine and ſmooth ones, reſembling iron, but very light, are found in, or near the mouths of the eruption, and ſome are very hard and heavy, and of a mixed nature, ſeeming to be the reſult of many ſorts of minerals melted together. Theſe latter, when the mountains have poured out ſtreams of fire, always remain in the places, and are the ſubſtance that was on fire cooled again.

At the time of the moſt terrible eruptions of this kind, theſe heaps of *ſciarri*, which ſometimes appear to be ſolid rocks of metalline matter, are only a ſort of covered arches, under which the melted matter yet continues liquid and running, and burſts out, at times, in the ſeveral parts of their ſides or ſurfaces. The general appearance of a train of theſe *ſciarri*, left after the eruption of ſuch a rivulet of fire, is much like that of the Thames, or ſome other ſuch large river, in the time of a ſevere froſt, the rocks of *ſciarri* riſing above the general ſurface, like the clods of ice in that ſcene; the colour only differing, the great quantities of the *ſciarri* in theſe places being of a deep bluiſh hue.

It is remarkable, that the ſubſtance of theſe *ſciarri*, even while melted and running in ſtreams down the hill, is ſo firm and ſolid, that no weight will ſink into it, nor any inſtrument make its way through the ſurface, any more than a ſolid maſs of cold metal. It has been ſuppoſed by ſome, that the flowing matter concreted into the common pumice ſtone, but that is a vulgar error, the pumice being a wholly different ſubſtance. Philoſ. Tranſ. N° 49.

SCIATHERICA, a name given to *dialing*. See DIAL and DIALING, *Cycl.*

SCIATHERICUM *teleſcopium*, a horizontal dial with a teleſcope, adapted for obſerving the true time, both by day and night, to regulate and adjuſt pendulum-clocks, watches, and other time-keepers. It is the invention of the ingenious Mr. Molyneux, who has publiſhed a book with this title, containing an accurate deſcription of this inſtrument, its uſes, and application.

SCIERIA, Σκιερια, in antiquity, a feſtival in honour of Bacchus, kept in Arcadia.

It was ſo called, becauſe that God's image was expoſed ὑπο τῃ σκιαδι, *i. e.* under an umbrella. At this time the women were beaten with ſcourges, in the ſame manner with the Spartan boys at the altar of Diana orthia, which they underwent in obedience to a command of the Delphian oracle. *Potter*, Archæol. Græc. Tom. I. p. 430.

SCILLONEORTE, Σκιλλων Ἑορτη, in antiquity, the feſtival of ſea onions. It was obſerved in Sicily. The chief part of it was a combat, wherein youths beat one another with ſea onions. He that obtained the victory was rewarded, by the gymnaſiarch, with a bull. *Potter*, Archæol. Græc. Tom. I. p. 431.

SCIMPODIUM, Σκιμποδιον, among the antients, a ſmall couch or bed, on which one perſon only could reſt at a time. It was on the *ſcimpodium* that the Romans uſed to lay themſelves, when weary or indiſpoſed.

The *ſcimpodium* was ſometimes uſed inſtead of the *lectica*, to carry both men and women, not only through the city, but likewiſe in journeys into the country. *Pitiſc.* in voc. See LECTICA.

SCINCUS, the *ſkink*, in zoology, the name of a ſpecies of lizard, called alſo by ſome the land crocodile, *crocodilus terreſtris*, and well known in the druggiſts ſhops as an ingredient in ſeveral compoſitions.

It reſembles the ſmaller ſort of lizards, being uſually about ſix inches long, and its uſual thickneſs is that of a man's thumb. It is of a ſilvery greyiſh colour, ſcaly, and has a rounded tail; its head is of an oblong figure; its noſe ſharp; and its feet, as it were, alated, having five toes each, armed with very ſharp claws. It is very common in Egypt and Arabia. *Worm.* Muſ. p. 86.

The dried fleſh of the *ſcincus* is greatly commended, as poſſeſſing all the virtues of that of vipers, but in a more exalted degree. It is ſaid to do wonders as a reſtorative, and provocative to venery. For this laſt purpoſe the belly is preferred to any other part of it; but there appears no reaſon for this in the dried animal. The people of Egypt cut the fleſh to pieces, and boil it down to a ſtrong broth or jelly; in which form it may do ſome ſervice, though it fails with us. The only uſe made of it at preſent in the ſhops, is as an ingredient in ſome of the old compoſitions.

SCINDALMOS, a word uſed by the antients to expreſs a fiſſure of the cranium, or of any other part.

SCINTILLA *veneris*, a term uſed by Paracelſus to expreſs a reſolution of the limbs, or deprivation of motion from a venereal cauſe.

SCIOGRAPHY, the art of ſhadows, or dialing. Alſo in architecture, it is ſometimes uſed to denote the draught of a building, cut in its length or breadth, to ſhew the inſide of it; as alſo the thickneſs of the walls, vaults, floors, timber works, &c.

SCIOMANTIA, Σκιομαντεια, in antiquity, a kind of divination, by raiſing the dead, who were ſaid to appear in airy forms like ſhades. *Potter*, Archæol. Græc. Tom. I. p. 350.

SCIOPODÆ, in hiſtory, the name given by Pliny, and other of the old writers, to a nation of people which they place in Æthiopia, on the burning ſands; and who they ſay, when too hot, lie down upon their bellies, and ſhadow themſelves from the ſun by lifting up their feet, which are very large and broad, againſt it. Theſe are ſome of the *gentes mirabilis figuræ* of Pliny, and are worthy to ſtand among the monocoli, and other ſuch monſters.

SCIRA, Σκειρα, a feſtival among the Athenians, otherwiſe called *ſcirrophoria*. See the article SCIRROPHORIA.

SCIRONA, a word uſed by ſome of the antients to expreſs the autumnal dews.

SCIRPUS, the *ruſh*, in the Linnæan ſyſtem of botany, makes a diſtinct genus of plants, the characters of which are; that the cup is an imbricated ſpike, made up of oval and bent ſcales, parting the ſeveral flowers. The flowers have no petals. The ſtamina are three long filaments; and the antheræ are oblong. The germen of the piſtil is extremely ſmall. The ſtyle is long and thread like. The ſtigmata are three in number, and extremely ſlender. The ſeed is ſingle, three cornered, pointed, and is covered with hairs, which

which are shorter than the cup. *Linnæi* Gen. Plant. p. 12. See Juncus.

SCIRRHUS (*Cycl.*)—The feat of a *fcirrhus* is very various and uncertain; for this diforder is not confined to the internal parts alone, to wit, to the liver, fpleen, lungs, mefentery, pancreas, and in females to the uterus; but it frequently happens alfo to the external parts, as to the lips, tongue, tonfils, fauces, palate, gums, neck, mammæ, axillæ, inguina, penis and tefticles, and that generally after inflammations of thofe parts; though it fometimes alfo appears without any inflammation, efpecially in perfons of a heavy phlegmatic habit; fometimes alfo it is occafioned by an external injury, as a fall, a blow, &c.

As foon as the *fcirrhus* is formed, the immediate confequence is, that the indurated part becomes unfit to perform the functions allotted by nature to it, and the neighbouring parts fuffer preffure, and become impeded in the performance of their feveral functions. It is therefore no wonder that they are found fubject, in thefe cafes, to inflammations, ulcerations, cancers, gangrenes, tabes, ftiffnefs, immobility, and the like, according to the nature of the injured part.

The more inveterate a *fcirrhus* is, the greater will be the difficulty in the cure. When this diforder happens to young people, and fuch as are of a good habit of body, it is much more fafe and tractable, than when it happens to older infirm perfons. When there is any thing venereal in the cafe, the difficulty is yet the greater. The *fcirrhus* is of the more or lefs confequence, according to the nature of the part it is feated in; and internal ones are always more dangerous, for this reafon, than the external.

While a *fcirrhus* continues free from pain, there is little danger from it; but when it becomes painful or ulcerated, it generally threatens a cancer. The cure of thefe diforders is always difficult and uncertain, but in young robuft habits fometimes the knife and corrofives will effect it.

When the *fcirrhus* is of long ftanding, and in old people, great care muft be taken how it is meddled with, left, while under treatment, it fhould become cancerous. On the other hand, when the *fcirrhus* is but newly formed, and you have no figns of vehement pain or hardnefs, where the patient is otherwife of a good habit of body, external and internal remedies are to be employed at once, to endeavour to fet the confined fluids at liberty. The internal remedies, found of moft fervice on thefe occafions, are the decoctions of the woods, digeftive tinctures, or mild mercurials, giving between whiles relaxing medicines, to refolve the infpiffated humors.

In regard to the external remedies, plafters made of the warm gums, as ammoniacum, galbanum, fagapenum, and the reft, either alone or mixed together, and affifted fometimes by the powder of bryony root, or of the birthwort, are ufed. Mercurials ferve greatly to this purpofe, and the following compofition is alfo excellent as a plafter on thefe occafions. Take galbanum and opoponax of each an ounce, ammoniacum and bdellium of each two ounces, oil of olives two pounds, yellow wax half a pound, powder of long and round birthwort, lapis calaminaris, myrrh and frankincenfe, of each one ounce, Venice turpentine four ounces; melt them all into a plafter.

Next to plafters, cataplafms are found highly ferviceable in thefe cafes, one of the beft of which is made in the following manner. Take white bryony root four ounces, round birthwort and angelica of each an ounce, leaves of favin, rue, fcordium, wormwood and camomile flowers, of each one handful; melilot, elder, marfhmallows and centaury, of each half a handful; let thefe be boiled together in a fufficient quantity of water to the proper confiftence for a cataplafm, adding, toward the end of the boiling, three ounces of galbanum, diffolved in the yolk of an egg, two ounces of linfeed meal, and as much as is neceffary of linfeed oil.

It is to be applied warm, and often renewed; and a fomentation made from the fame ingredients, boiled in vinegar, is often found alfo of great ufe.

Inftead of thefe remedies fome highly extol the ufe of acid vapours on this occafion; fometimes the fteam of boiling vinegar is ordered to be received on the part, and that either of plain vinegar, or of fuch as has been medicated by infufions of rue, lavender flowers, or other fuch ingredients, or of the Venice treacle. Some fprinkle vinegars of thefe kinds over a hot ftove, and receive the vapour through a funnel; others advife the burning of common brimftone, and holding the part over the fume; and others are fond of fumigations of cinnabar. Great care muft be taken in thefe cafes not to raife too large a fume, nor to keep the patient over it too long; and he muft be advifed not to admit it into his nofe or mouth, for all thefe fteams are injurious to the lungs; and in the laft cafe, the quantity of mercury raifed in vapour from the cinnabar may often be enough to raife a falivation.

Mercurial medicines are alfo found to perform wonders in thefe cafes, either adminiftered in the beginning, or after all other remedies have failed. Befide giving mercurials internally, an excellent mercurial ointment may be made, by mixing quickfilver firft with a fmall quantity of Venice turpentine, and afterwards with a much larger of hog's lard, by rubbing them together in a glafs or marble mortar. The *fcirrhus* fhould be anointed two or three times a day with this, covering it with a common mercurial plafter; and to prevent this method from raifing a falivation, fome purging medicine, as the extract of rudius, or jalap, is to be given in fmall dofes every fourth or fifth day.

But if all thefe methods prove unfuccefsful, and the *fcirrhus* is free and moveable, and its fituation threatens no danger from the neighbourhood of any confiderable veffels, and if the patient's ftrength fhall be judged fufficient to undergo the operation, the affiftance of the knife muft be called in, and the *fcirrhus* cut out, to prevent its growing cancerous. When the *fcirrhus* is thus taken out, the wound is to be dreffed and healed with the common vulnerary balfams: but when the *fcirrhus* is fixed, knotty, uneven, and deeply rooted; where the patient is of a bad habit of body, is fubject to form *fcirrhufes* from an hereditary taint, or has formed feveral already; and laftly, where the fituation of the diforder is fuch, that from the vicinity of confiderable veins and arteries, there is danger of bringing on an hæmorrhage, which may prove fatal, then all attempts to cure, whether by the knife, by digeftives, or by corrofive medicines, are to be neglected; for this kind of *fcirrhus* is almoft always attended with very violent pains, and all that can be done is to attempt to alleviate thofe pains, and prevent a cancer. *Heifter*'s Surgery, p. 221.

Scirrhus *hepatis*, in medicine, a difeafe confifting in an indurated tumor of the liver, occafioned by a ftagnation of the humors which grow thick there, from an exhalation of their more fluid and fubtle parts.

This differs from the *infarctus hepatis*, not only in degree, but in its fymptoms, for it almoft always is attended with a hectic, or with œdemato-hydropic fwellings. *Junker*'s Confp. Med. p. 208.

Signs of it. Thefe are a tumor and hardnefs in the right hypochondrium, or region of the liver, always evident to the patient, and often fenfibly perceived by any body elfe, on touching the part. To this are to be added dull tenfive pains, and a fenfe of a weight hanging there, and ufually afthmatic fymptoms, and a dry cough. It becomes painful to lie on the left, or oppofite fide; and with thefe a hectic comes on, with a wafting of the upper parts, and a fwelling of the inferior ones; firft of the feet, but afterwards upwards to the belly, which finally become very obftinate, and truly afcitic. The urine in this cafe is fmall in quantity, and of a deep orange colour, and thick confiftence. It has ufually a mucid fediment, and fometimes a thick one of a rofe colour.

Caufes of it. Thefe are ufually either an omiffion of artificial difcharges of the blood, by habitual bleedings at fpring and autumn, or a fuppreffion of the natural ones, by the menfes or hæmorrhoidal veffels: an improper treatment of intermittent fevers with aftringents, of quartans with large quantities of bark, and of acute fevers with too cooling a regimen, or a violent quantity of the volatile falts, or a condenfation of the humors in a fimple infarction, by means of cold external applications. The ftopping hæmorrhages, which nature had brought on for her relief in plethoras, have alfo been fometimes known to occafion a *fcirrhus* of the liver; as have alfo external injuries by blows, falls, and the like.

Prognofticks. A recent *fcirrhus* of the liver admits of a cure, but this not without great difficulty, and in a more confirmed one there is very little hope. This tumor has a continual tendency to corruption, either by fphacelation, or by an inflammatory fuppuration; neither of which can happen fuccefsfully, for the firft muft occafion inftantaneous death, and the latter exulceration, and a fucceeding fatal hectic. A *fcirrhus* of the liver often follows, and fometimes precedes a jaundice of the moft violent kind.

Method of treating it. The bowels are firft to be cleanfed and relaxed by a clyfter, made of a decoction of mallows, camomile flowers, mullein, and fennel feed; after this, bleeding in the foot is to be ordered, and then the nitrous and other refolvent medicines are to be given, fuch as tartar of vitriol, and the like. After this medicated wines fhould be drank as the common drink, prepared with bryony and arum roots, centaury, hyffop, and maidenhair leaves, faffafras, fenna, black hellebore, and rhubarb; and externally, plafters of the refolvent and ftrengthening kinds are to be applied. But after all directions for the treatment, it is to be acknowledged, that an obdurate and inveterate *fcirrhus* admits of no remedy. *Junker*'s Confp. Med. p. 210.

SCIRRONES, a name given to a fort of fmall lice breeding under the fkin.

SCIRROPHORIA, Σκιῤῥοφορία, in antiquity, an anniverfary folemnity at Athens, upon the twelfth day of the month *fcirrophorion*. For its origin and ceremonies fee *Potter*, Archæol. Græc. lib. 2. cap. 20. Tom. I. p. 430.

SCIRROPHORION, Σκιῤῥοφοριων, in antient chronology, the twelfth and laft month of the Athenian year. It contained

 twenty

twenty nine days, and anfwered to the latter part of our May and beginning of June. See MONTH.

It had its name from the feaft *fcirrophoria*, kept in it.

SCISSIMA, in botany, a name given by fome authors to the beech tree. *Ger.* Emac. Ind. 2.

SCISSORS. Mr. Monro has given us the figure and defcription of a pair of *fciffors*, the blades of which are crooked on their flat fides. Thefe *fciffors* are very ufeful for taking off excrefcences from hollow parts, or for cutting in curve lines, which the common *fciffors* cannot eafily be applied to. Med. Eff. Edinb. Vol. 5. art. 41.

SCIURUS, the *fquirrel*, in the Linnæan fyftem of zoology, makes a diftinct genus of animals, the characters of which are; that the creatures have four toes on the fore feet, and five on the hinder, with palms made for climbing and leaping, and all have woolly tails. *Linnæi* Syftem. Natur. p. 33.

We have five fpecies of this little animal defcribed to us. 1. The common Englifh kind. 2. The great grey Virginian one. 3. The black backed kind of Ceylon. 4. The American flying *fquirrel*. And 5. the Barbary kind.

The common Englifh *fquirrel* is well known, and is diftinguifhed from the others by its fize and colour. It is fomething larger than the weafel, but fhorter bodied; its back and fides are reddifh; its throat and belly white; and it generally carries its long hairy tail erect over its back, fo that it ferves it for a fhade. It is common in our woods, and feeds on all forts of fruit, but principally on hazel nuts; which it gathers in the feafon, and lays up for its winter ftore. The fame fpecies of *fquirrel* with ours is found in Poland and Ruffia, grey or afh coloured.

The fecond, or great grey American *fquirrel*, is very common in Virginia, and is of the fize of a rabbet. It is of a dark iron grey, fuch as fome rabbets are of; its fore feet have only four toes, its hinder ones five.

The third, or black backed *fquirrel*, is found in the ifland of Ceylon, and called by fome *rukkaia*, from the noife it makes. The hair on its back is fometimes grey.

The fourth, or flying *fquirrel*, is a very fmall kind; its back is of a dufky moufe-coloured grey; its throat and belly white; its eyes fmall, black, and prominent, refembling thofe of the moufe kind; its tail is very long, and very broad and flat. It has a thin and lax fkin on each fide, which is fixed to the fore and hinder legs, and confequently, on the extending its legs, this fkin expands on each fide like a fort of fail: this it always does in leaping, and is by that means carried a great way; and hence has arifen the opinion of its flying. It is very common in New Spain, and is fometimes met with in the colder American countries. It very much approaches to the moufe kind in many particulars, receding from the nature of the *fquirrel*. Its furr is fhort like that of the rat or moufe, not long like the other *fquirrels*. It never erects its tail on its back, nor turns or twifts it round, as the other *fquirrels* do. It has a very beautiful black line on each fide the face, near the eyes.

The fifth kind, or Barbary *fquirrel*, is of a mixed colour, between black and reddifh, and is very beautifully variegated all down the fides with brown and white longitudinal ftreaks, laid in a regular alternate order, and each reaching the whole length of the body. Thefe lines are, in fome of thefe creatures, not brown and white, but black and white; and the tail, when in a ftate of reft, is feen elegantly ftreaked with the fame colours, but when the creature erects it, the hairs ftanding all upright, the beauty of this variegation is hid. The belly of this creature is blue and white. It is fmaller than our *fquirrel*, and has fhorter ears, which are roundifh, and lie clofe on the head. The whole head has much of the figure of a frog's, in all other refpects it is perfectly like our *fquirrel*. *Ray*'s Synop. Quad. p. 214.

SCLAREA, in botany, the name of a genus of plants, the characters of which are thefe. The flower confifts of one leaf, and is of the labiated kind; the upper lip is hooked like a reaper's fickle, and the under one divided into three fegments, the middle one being largeft, and hollowed like a fpoon. The piftil arifes from the cup, and is fixed in the manner of a nail to the hinder part of the flower. It is furrounded by four embryos, which ripen into as many feeds, and are contained in a fort of tubular capfule, which was the cup of the flower.

The fpecies of *fclarea*, enumerated by Mr. Tournefort, are thefe. 1. The *fclarea*, called *gallitrichum fativum* and *orvala* by authors. 2. The woolly *fclarea* with very large flowers, called *Æthiopis* by many authors. 3. The jagged leaved *fclarea*, called the *Æthiopis* with divided leaves. 4. The large leaved glutinous Portugal *fclarea*. 5. The afphodel rooted *fclarea*. 6. The Indian *fclarea* with variegated flowers. 7. The glutinous Pyrenean *fclarea* with finuated leaves. 8. The ftinking hairy white flowered *fclarea*. 9. The early African annual *fclarea*. 10. The great annual Bœtic *fclarea* with pale blue flowers. 11. The blue flowered meadow *fclarea* with ferrated leaves. 12. The white flowered meadow *fclarea* with ferrated leaves. 13. The bright red flowered meadow *fclarea* with ferrated leaves. 14. The greater *fclarea* with deeply divided leaves. 15. The white flowered Syrian *fclarea*. 16. The blue flowered Syrian *fclarea*. 17. The great fpotted fage leaved *fclarea*. 18. The fmall fmooth fage leaved *fclarea*. 19. The purple flowered fage leaved *fclarea*. 20. The *fclarea* with triangular dentated leaves. 21. The triangular leaved woolly ftalked *fclarea*. 22. The blue flowered betony leaved *fclarea*. 23. The African fhrub *fclarea* with leaves like the helianthemum. 24. The large flowered dwarf *fclarea* with jagged leaves. And 25. the Syrian *fclarea* with rugged dentated leaves. *Tourn.* Inft. p. 179.

SCLERIA, a word ufed by medical writers to exprefs a hardnefs of the inner part of the eyelids.

SCNIPS, in natural hiftory, a name given by authors to the fmall fpecies of gnat, always found about the oak tree feeding on the juices of its leaves, which it fucks by means of its fharp trunk.

It is fuppofed by fome to be hatched of the fmall oblong white worm, that inhabits the oak apples.

SCOBS, a word ufed by fome authors to exprefs the rafpings of ivory, hartfhorn, or other hard fubftances. Some alfo have ufed it to exprefs the fcoriæ of metals; and fome as a name for the *cineres clavellati*, or pot-afhes, ufed in foap and glafs-making.

SCODEGHINO, a name given by chirurgical authors to a peculiar fpecies of incifion knife, defcribed by Scultetus, and ufed by Rouffet in performing the Cæfarean operation.

SCODINEMA, a word ufed by fome medical writers to exprefs a heavinefs of the head.

SCOLECIA, in the materia medica of the antients, a name given to a kind of verdigreafe.

Of this there were two fpecies, the one found native in the earth, the other fictitious.

The latter kind was prepared by rubbing a quantity of vinegar in a brafs mortar, with a brafs peftle, till it became thick and ropy; when it was in this condition, a fmall quantity of alum and fea falt, or nitre, were added to it, and it was fet in the fun in the heat of the dog days. It was to ftand thus till it became ropy, thick, and of a green colour; and then being drawn out into long threads, and dried, it had the refemblance of worms in fhape, and thence had its name.

SCOLION, among the antients, a kind of Bacchanal fong ufed at entertainments. See *Pitifc.* in voc.

SCOLIOSIS, a word ufed by Hippocrates to exprefs a diftortion of the fpine fideways.

SCOLIUM, in antiquity. See the article SCOLION.

SCOLOPAX, the *woodcock*, a very well known bird, diftinguifhed by its fize, which is fomewhat fmaller than that of the partridge, and by its colour, which is on the back a variegation of black, grey, and a reddifh brown; and on the belly a pale grey, variegated with tranfverfe ftreaks of brown. Its beak is three fingers breadth long, and the upper chap a little longer than the under.

In the Linnæan fyftem of zoology, the *fcolopax* is the general name of a large order of birds, the diftinguifhing character of which is, that they have a fomewhat cylindric beak, which is rounded, and obtufe at the point. *Linnæi* Syftem. Natur. p. 47.

SCOLOPAX, in ichthyography, the name of a fea fifh called in Englifh the *trumpet*, or *bellows fifh*.

It is a very fmall fifh, caught very frequently in the Mediterranean, and common in the markets of Rome, Venice, and elfewhere. Its common length is about three inches; its body is flat, and of about one finger's breadth, and covered with rough and harfh fcales. The fnout is extremely long, and is hard, ftrait, and made all of one bone, broad at the head, and narrow at the end, and opening there tranfverfely with a membrane affixed to the under jaw, and ferving to open and fhut it at pleafure. The eyes are large, and their iris's of a pale red. It has a thin fin at each of the gills. The anterior part of the belly is formed into a fharp edge, and has no fins, but two bony fubftances, feeming the rudiments of belly fins; and a little lower on the belly it has one, which is longer and notched. Behind the anus there is a long fin, reaching to the tail, and on the back there are two others very oddly placed; the hinder ftands very near the tail, the other higher up; and this laft is no other than one long and large bony fpine of two inches long, and fet in a joint, by which it is moveable at pleafure. Before this there ftands another very fine prickle, and behind it three others, which make the whole a fort of fin. *Gefner*, de Pifc. p. 1008.

SCOLOPENDRA, in zoology, an infect of a very flender and long body, very fmooth, and of a yellowifh or reddifh colour, furnifhed with a vaft number of legs, and having two long antennæ, and a bifid tail.

It is ufed by fome as a depilatory, being boiled in wine. *Dale*'s Pharmacop. p. 355.

There is a fpecies of this animal, which naturally fhines in the dark in the manner of a glow-worm, but with a fainter and more general light. Every part of the body of this animal will emit fparks, if preffed in the dark. It is covered with a foft down, or fhort and fine hair, much refembling in texture

ture the dewny matter which grows on the back of colts-foot leaves.

The two fides of the animal are covered alfo with two other lifts or ftripes; thefe go off from the main ftripe at the top, and thefe are about a quarter of an inch broad; they are covered with a fine and foft hairynefs, of more than a quarter of an inch long, of a fine changeable red and green colour, and of prodigious beauty and brightnefs. Among this long hair of the ftripes on the fides there are fet a vaft number of long and fharp prickles; they are about the fame length with the hair, but they are as ftiff as a hog's briftle, and are very fharp at the points, and of a black colour; there are feveral hundreds of thefe on the two fides. The tail, or fmaller end, terminates on the back in two fcales, which are very bright and fine; under this is the anus, at which the creature voids its excrements. The larger end has no part of the common characters of a head, except the mouth; but as it has this, and ftands oppofite to the tail, it is properly enough called fo in defcription. It has no horns, no eyes, nor any other of the common organs of infects heads.

The mouth is very wide, in proportion to the fize of the creature, and is not placed at the extremity, but fomewhat under the belly part; fo that when the back of the creature is viewed, the mouth is not feen. The belly is fmooth and flat, and is covered with a thin fkin, much paler coloured than that of the back, and irregularly variegated with a number of brown fpots, of different fizes and fhapes. Within an inch of the tail there are feen on this under part feveral marks, like thofe of the annular divifions of the bodies of infects, but they do not fhew themfelves on the back. The legs are placed in two rows, each of the whole length of the body of the fifh; they begin from the angle of the mouth on each fide, and are continued to the tip of the tail. Thofe ftanding near the mouth are longer than the others, which gradually decreafe till they are very fhort at the tail; the longeft are about a quarter of an inch in length, and the fhorteft not a fixth of that length.

The whole number of legs is feventy two, thirty fix ftanding on each fide. From within the body, through the middle of each leg, there paffes a clufter of three or four prickles; thefe are larger or fmaller, according to the fize of the leg, and vary alfo in number, the longeft legs having moft of them; they give ftrength and firmnefs to the legs, ferving them in the place of bones, and iffuing out beyond the end of the leg, in the way of claws; they ferve the creature for the laying faft hold of any thing it pleafes. On each fide of the upper, or back part of the fifh, there are alfo placed a number of foft, flat, and fmooth fins; thefe ftand near the legs, and are placed face to face in fuch a manner, that each foot has its correfponding fin. The fins are exactly of the fame number with the legs, and, like them, are largeft toward the head, and go off gradually tapering toward the tail.

Thefe ferve the creature in the office of a fifh, giving it power to fwim in the water, as the others ferve it as a reptile to crawl upon the ground at the bottom. The fins on each fide are fringed with the fame changeable coloured hair, that the ftripes on the back are.

On opening the body there appears a mufcular organization, elegantly contrived for the working fo great a number of legs and fins. This appears in form of one large and broad red mufcular congeries, and from this there are propagated on each fide thirty fix pair of rays, or oblong and flender mufcles, every pair ferving for the motion of one leg and one fin. Thefe are very diftinctly vifible, and reprefent the fpine and ribs in fome fifh. And in this the wonderful care of nature is feen, in regard to this little animal, which, by means of thefe diftinct mufcles, is able to move every fingle leg or fin feparately, and confequently can put as many, or as few as it pleafes, in motion at a time. It is plain alfo, from the ftructure of the body of this creature, that it can at pleafure roll up its body into a round form, and in that cafe will appear as a globe covered with long and fharp prickles: this is probably its practice, when in danger of being devoured, and may ferve it on many occafions. It has been thought by fome, that Rondeletius means this creature by his *phyfalus*; but this does not appear to be the cafe on a careful examination. Philof. Tranf. N° 225.

Scolopendra *marina*, a name given by Dr. Molyneux to a new fpecies of fea animal, of the centipede *fcolopendra* kind. See Tab. of Microfcopical Objects, Clafs. 1.

This remarkable infect, taken in the Irifh feas, is evidently the fame animal defcribed by Oligerus Jacobæus, in the *Acta medica Haffnenfia*, under the name of *vermis aureus*, or *erucæ marinæ fpecies rarior*. It was caft on fhore in Holland, at Katwik op Zee; and Aldrovand feems to have meant it alfo under the name of the broad bodied chefnut coloured fea *fcolopendra* with numerous yellow feet. The figures and defcriptions in both thefe places are however very imperfect, and the account given by Dr. Molyneux is the only one at all to be relied on, of this ftrange animal. Philof. Tranf. N° 224.

Scolopendra *fcutata*, in natural hiftory, the name of an animal of the infect kind, found in the year 1736 by Klein in Pruffia, and at the fame time by Mr. Brown in fome parts of Kent.

It was met with in Pruffia in vaft abundance, in the places where they take crayfifh, and having not been met with there before, furprifed the people employed in that fifhery fo much, that they brought home many of them. In Kent its appearance was attended with greater fingularity, Mr. Brown found it in a pond on Bexby common, where the country people had obferved vaft numbers of them for five or fix weeks before. This pond was quite dry on the 24th of June that year, but being filled by the thunder fhower on the 25th of the fame month, the pond was obferved to fwarm with them in two days, by a farmer watering his cows there; and what is very obfervable is, that there appears no channel into this pond, that could convey them from any other place.

The creature is about an inch and half in length, and fomewhat lefs than an inch in breadth, and though fo fmall, yet bears a great refemblance, in many of its parts, to the great Molucca crab, called by fome the *buckler crab*. When the back is viewed, it is feen to be covered with a cafe or fhield, fo that it in fome meafure refembles a tortoife, only it is remarkably gibbous, or prominent all along the middle of the back, and has a triangular opening in the fhell near the tail. This covering is of the confiftence of the upper wings of the beetles, and the eyes are prominent, and placed beyond it. When the creature is turned upon its back, fo that the belly comes in fight, there are obferved a vaft number of legs, and every one of thefe is furnifhed with a fort of bag at the end, which finally divides itfelf into feveral fingers or toes, and all thefe are compofed of a number of articulations, in the manner of the antennæ of the common infects. There iffue from the tail two long and flender bodies, articulated in the fame manner; thefe are about a third of an inch in length, and greatly refembling the common antennæ. On the head alfo it has two fhort horns, ftanding in the common place of the antennæ. When the cafe or fhell is taken off, the rings of the body are found to be about thirty in number. The legs are very extraordinary, they are forty two on each fide; the twenty that ftand next the head are nearly of the fame fize, but then they grow gradually fmaller towards the tail. The feet confift each of five membranaceous claws; thefe are flat, and have a ftiff rib in the middle, and are hefet at the edges with hairs, in the manner of the legs of a crab. On the lower fide of the leg hangs an oval bag; and beyond that grows a large thin membrane, which can be extended at the creature's pleafure by means of a ftrong rib, which runs all the way along its middle. This membrane, and alfo the whole foot, are convex toward the head, and concave on that fide that ftands toward the tail; the thigh, or firft joint of the leg, is webbed on each fide, and indeed the whole ftructure of the legs feems calculated for fwimming, rather than for walking. Philof. Tranf. N° 447. p. 151.

SCOLOPENDRITES *lapis*, in natural hiftory, a name given by fome authors to a fpecies of the *lapis fyringoides*, or pipe ftone, the tubules of which they fuppofed to refemble the figure of the body of the *fcolopendra*.

SCOLYMUS, in botany, the name of a genus of plants, the characters of which are thefe. The flower is compofed of a number of femiflofcules, each placed on an embryo feed, and perforated in its bottom part by the capillament which runs out from the embryo. The femiflofcules are feparated each from the next by a little leaf, and are all contained in a fquammofe cup. The embryos afterward become feeds affixed to the thalamus of the flower, and adhering to thofe little leaves which feparated the femi-flofcules. See Tab. 1. of Botany, Clafs 13.

The fpecies of *fcolymus*, enumerated by Mr. Tournefort, are thefe. 1. The *fcolymus* with gold yellow flowers, called by authors the *yellow flowered thiftle*, and the *yellow thorn*. 2. The annual yellow flowered *fcolymus*. And 3. the tall African yellow flowered *fcolymus*. *Tourn.* Inft. p. 489.

It is not certain that any of the antients ufed the word *fcolymus* as the name of the plant we call the artichoak. Theophraftus, Diofcorides, and indeed all the antients, have defcribed this plant; but Theophraftus fays that only its roots were eatable, and Diofcorides fays fo of its young fhoots. It feems, therefore, that they meant our chardon by this name, the ftalks of which our gardiners have a way of blanching for the table.

Thefe Greek writers had indeed another name for the artichoak, they called it *acanthe*. This cannot be doubted by any, who will obferve their accounts of the *acanthe*, which tell us that it was of the thiftle kind, but had a large and roundifh head, compofed of fcaly leaves, in the manner of the cone of the fir or pine, (the pine apple as we vulgarly call it) and that in this head was contained its only efculent part.

This name *acanthe* being very like the word *acanthus*, the name of the *branca urfina*, or bear's breech, there have been many errors in the editions of the antient Greeks,

 by

by confounding the two words. *Dioscorides*, lib. 18. *Theophrastus*, p. 72. See ACANTHE.

SCOMBER, the *mackrel*, a well known sea fish of the thynnus kind, and distinguished from the other fish of that genus by its extremely small and thin scales; by its bluish green colour on the back, variegated with undulated and crooked black lines; by the forkedness of its tail, and the very substance of the fin of it, being almost entirely wanting at the angle of it; and by the largeness of its eye, in comparison of the *amia*, and other fish of this kind, which most resemble it in other respects. *Willughby's* Hist. Pisc. p. 181.

In the Linnæan system of zoology, the *scomber* is a distinct genus of fishes, of the general order of the acanthopterygii. The characters of this are, that the membrane of the gills has seven bones, and that the tail has lateral eminences. Of this genus are the *scomber*, *thynnus*, *amia*, and *trachurus*. *Linnæi* Syst. Nat. p. 54.

In the Artedian system of ichthyology, the characters of this genus of fish are these: the branchiostege membrane on each side contains seven slender bones, the upper one of which is nearly covered by the covering of the gills. The tail is very forked, so as to resemble the form of a crescent. There are one or more eminences on each side toward the tail. The fins are either only two on the back, or else, beside these, there are several other small and short ones, running all the way to the tail, as well on the upper as the under part of the body. The appendices to the pylorus are very numerous.

The species of this genus are these. 1. The *scomber* with five pinnules at the end of the back, and a short spine at the anus. This is the common *mackrel*. 2. The *scomber* with eight or nine pinnules at the end of the back, and a furrow at the belly fins. This is the *tunny* fish. 3. The *scomber* with prickly lateral lines, and thirty bones in the pinna ani. This is the fish we call the *horse mackrel*, and in some places the *scad*. 4. The *scomber* with two back fins, and with the last ray of the second very long. This is the *amia* of Salvian, and the *glaucus* of Aldrovand. It grows to three feet long. 4. The *scomber* with the second ray of the second back fin very high. This is the *glaucus primus* of Willughby and Rondeletius. *Artedi*, Gen. Pisc. p. 25. See the articles GLAUCUS, &c.

SCOPELISMUS, Σκοπελισμος, an audacious crime practised by some villains among the Arabians.

It consisted in placing a certain number of stones upon the farm or field of persons these miscreants had a pique at; which stones served as a denunciation of utter destruction to those, who for the future should attempt to till the ground on which they were laid. And such terror attended this malevolent and clandestine threatening, that none ever ventured to till such fields. *Pitisc.* in voc.

SCOPS, in zoology, the name of a bird of the horn owl kind.

It is the smallest of all the owl kind, being scarce so large as a pigeon, and is grey on the head, and of a whitish brown, variegated with streaks and spots of brown in other places. Its beak is short, black, and crooked, and it has two series of feathers, like the rest of the horn owls, resembling horns, which stand over its ears. It is very common in Italy. *Aldrovand.* de Avib. lib. 8. cap. 4. *Ray's* Ornithol. p. 65.

SCORAX, a word used by some authors to express the gum of the olive tree.

SCORDIUM (*Cycl.*)—This plant is propagated in our gardens for medicinal use, by parting the roots, or planting slips or cuttings in March, in beds of moist earth, at four or five inches distance, in July they will be in flower, and fit to cut for use. But every other year the bed should be renewed, and that always on a fresh spot of ground, for they do not succeed well on the same. *Miller's* Gardner's Dictionary.

Scordium, or *water germander*, is esteemed a great sudorific and alexipharmic. It is prescribed in malignant and pestilential fevers, and even the plague itself. It is an attenuant and dissolvent, and is used to destroy worms. Externally it cleanses foul ulcers, and, applied by way of cataplasm, mitigates pain. It is never used alone, but merely kept in the shops as an ingredient in the *confectio Fracastorii*, which, though it contains several medicines of more virtue, yet takes its name *diascordium* from it.

SCORIA, (*Cycl.*) in metallurgy, the recrements of metals in fusion, or more determinately speaking, the mass, or part of the mass of a melted metal, converted by the action of the fire into a body, which when cold is brittle, fixed, not dissoluble in water, but melts again when exposed to the fire, and is properly a kind of glass.

Some authors call by this name that saline mass, which is produced by melting ores and metals together with saline, and reducing fluxes. But the word *scoria* is not properly to be understood of all this mass, but only of the vitrified particles which are lodged between, and adhere to the small masses of the salts, and which may be separated from them by water. *Cramer's* Art of Assaying, p. 185.

SCORIFICATION, in metallurgy, is the art of reducing a body either entirely, or in part, into *scoria*.

It is used by metallurgists, in order that any metal, imprisoned in a solid body, may, on account of its weight, descend and separate itself therefrom, and finally if that be required, be itself either wholly or in part converted into *scoria*. All fixed bodies are subject to this alteration, not totally excepting even gold and silver. There are also, among the volatile bodies, some that may be fixed, and which assume the form of *scoræ*, by adding fixed bodies to them.

It is often proper to make this *scorification* in a vessel that may absorb the *scoriæ*, and retain only the metallic part of the mass under trial. In this case the operation is called *cupelling*, and vessels made of ashes, called *tests* and *coppels*, serve for this purpose. It is evident in these processes, that a great attenuation of the *scoriæ* is necessary, that they may be able to pass through the vessel; nor is there any fitter body to promote this operation than lead, which, by its undergoing itself a like attenuation in the fire, disposes other bodies to be reduced into a subtle *scoria* for the same attenuation.

SCORITH, a word used by the chemical writers to express sulphur.

SCORPÆNA, in the Artedian system of ichthyology, the name of a genus of fishes, of the acanthopterygious kind, the characters of which are these. The branchiostege membrane on each side contains seven bones. The head is large, and very prickly. There is only one back fin, and that is lower in the middle than elsewhere. The body grows small toward the tail. The eyes are placed near one another, and are covered with the common skin. There are teeth in the jaws, palate, and fauces; and the appendices to the pylorus are eight or nine.

The species of this genus are these. 1. The *scorpæna* with pinnules at the eyes and nostrils. This is the *scorpius minor*, or *scorpæna* of authors. 2. The red *scorpæna* with many cirri about the mouth. This is the *scorpius major* of authors, and is three or four times larger than the other. *Artedi*, Gen. Pisc. 33.

According to Mr. Willughby, the *scorpæna* is a fish of the anguilliform kind, called by the people of Cornwall *father lasher*.

It is of about six inches in length, and in shape much resembles the fresh water bullhead. Its head, and the forepart of its body, are very large, the hinder part smaller, the belly is flat and broad, and the whole body is without scales. It has a rough line running along both sides. It is variegated with black and yellowish marks, and the belly is white. The mouth is large, and is furnished with several rows of small teeth. It has large fins at the gills, and two on its back, which are somewhat prickly, and one strait one on the belly. It keeps about the shores, and feeds on shrimps and small fish. It is common in the Dutch and English seas.

Scorpæna is also the name of a fish caught in many parts of the Mediterranean. It seldom grows to more than a pound weight. Its body is of a long, not flatted form, and is moderately thick. Its head is extremely large, and is armed with prickles, and it grows gradually less from thence to the tail. Its belly is not flat, but tumid, and its back rises in the middle. It something resembles the river pearch in shape, and is of a yellowish colour, variegated with spots of brown. Its scales are small and rigid. The coverings of the gills are armed with spines, and there are others about the eyes and about the mouth. The space between the eyes is hollowed, and over each eye there is a sort of small fin. The eyes are large and prominent, and are placed near one another. Its mouth is extremely large, but its teeth small. It has only one back fin, but that being very low in the middle, gives an appearance of two. The anterior spines of this are rigid and prickly, the hinder ones soft and flexile. The prickles about the head are accounted venomous, and the fishermen usually cut them off as soon as the fish is caught. Its tail is not forked, but rounded at the end. The belly and bellyfins are reddish. *Gesner*, de Pisc. p. 1018. *Aldrovand.* de Pisc. lib. 2. cap. 24.

SCORPIACA, the name of an antidote recommended by Galen against the stinging of scorpions.

SCORPIO, the *scorpion*, in zoology. See SCORPION.

SCORPIO, in botany, a name by which some of the old authors have called the *genista spinosa*, or common furze bush. *Ger.* Emac. Ind. 2.

SCORPIOIDES, in zoology, the name of a fish of the gotturugine kind, but differing in colour, being of a faint green, variegated with black spots; and in either wanting the eyefins, or else having them extremely minute. *Rondelet.* de Pisc. See GOTTORUGINE.

SCORPIOIDES, in botany, the name of a genus of plants, the characters of which are these. The flower is of the papilionaceous kind; the pistil arises from the cup, and finally becomes a jointed pod of an oddly convoluted shape, resembling a snail or caterpillar, and usually containing in each of its joints a single oval seed. See Tab. 1. of Botany, Clas. 10.

The

The species of *scorpioides*, enumerated by Mr. Tournefort, are these. 1. The *scorpioides* with beupleurum, or hare's ear leaves. 2. The beupleurum leaved *scorpioides* with rough, and more contorted horns. 3. The *scorpioides* with thick pods. 4. The *scorpioides* with beupleurum leaves, and with smooth pods. 5. The *scorpioides* with cochleated and striated pods. *Tourn.* Inst. p. 402.

SCORPION (*Cycl.*)—The opinions of authors are very different as to the sting of this creature; some asserting that there is an opening in it, through which a poisonous liquor is thrown into the wound made by it, as is the case in the tooth of the viper, &c. and others affirming that there is no such opening.

Galen affirms that there is none, but most of the writers of the middle ages assert that there is. But the whole is set in the clearest light by Segnior Redi, who took the pains of examining microscopically the stings of *scorpions* brought alive from Tunis, Egypt, and Italy. These he nicely examined by the best glasses in the Musæum of the Great Duke of Tuscany, and could find no aperture: but not satisfied with this, he pressed the stings, to try if he could make any liquor flow out of them; they were, however, so hard and horny, that squeezing could have no effect on them; and finally he caused a *scorpion* to strike upon a plate of iron, but no liquid was found thereon; so that he began to conclude Galen's opinion right, when he accidentally discovered an exceedingly small drop of white liquor upon the sting, and this he afterwards found in all the trials he made with several *scorpions*. And Mr. Lewenhoek discovered an opening on each side of the sting of this creature, for the emission of the poison, which he supposes is not discharged, till the sting is buried in the wound. *Baker's* Microscope, p. 213.

Mr. de Maupertuis, having caused *scorpions* to bite several animals, of which very few died, or suffered any more than the pain of the sting, is of opinion, that oil of *scorpions* and other vulgar antidotes to the poison of these animals, have rather got their reputation from the innocence of the sting of these creatures, than from any considerable virtue in the medicines. Mem. de l'Acad. Scienc. 1731.

Water SCORPION, *scorpio palustris*, a name given to a very remarkable species of water insect. It is a very thin and light little creature, yet is but a very slow mover. Its head is very small, and is hard to the touch, and of a paler brown than the rest of the body; and this is terminated by a very fine and sharp hollow proboscis, of the same colour and texture. The eyes are small, but prominent, and are very hard and black. The shoulders are broad and flat; they are of the same colour with the head, and are wrinkled on the surface. The triangular spot between the wings is black and shining, the body is of a bright red lead colour on the back, and of a faint dusky brown on the belly, and is composed of six joints, covered with a sort of scales. The outer wings are very hard and firm, and lie very far over one another; they are opake, and of a dark muddy brown, without any variations: the inner wings are of a dusky white, veined with a red lead colour. The two fore legs are broader and thicker than the rest, and end in short blunt claws; these the creature never walks with, but always uses them as arms: the hinder pair are the longest, and both they and the middle ones end in a sharp claw; they are all of a pale brown, and somewhat transparent. The tail is long and strait, it is composed of two slender bristles, of a pale brown; the creature scarce ever separates these. It lives among the weeds in clear standing waters, and is continually watching for its prey. It feeds on other insects, and is particularly fond of the *cicada aquatica*, or worm of the great libella. It seizes its prey with the fore legs, and holds it fast in them while the proboscis pierces into the body, and sucks the juices. See Tab. of Insects, N° 8.

SCORPION *fly*, in natural history, a name given by Mouffet and other writers to a kind of fly, remarkable for carrying the end of its tail turned up in form of the *scorpion's* sting.

There are two very beautiful species of these. The one has silvery wings, variegated with three transverse streaks of black toward the ends; the head is black, and the breast, shoulders and feet whitish; the rest of the body is black. The tail, which represents a sting, has five joints, three of which are red, and the others black; the end of the tail also is forked, and the forks black, and turned up like the sting of a *scorpion*.

The other resembles this in many respects, but the end of the tail is thicker, and the forks blunter; the head is dunish, the mouth long, and each wing variegated with six black spots, of a large size.

SCORPIUS, in ichthyology, the name of a fish caught in the Mediterranean, of a long and rounded body, not flatted, and with a very large head, from whence it gradually grows smaller to the tail. See Tab. of Fishes, N° 61.

It grows to three or four pounds weight, and is of a reddish colour, variegated with brown and blackish spots. It has several short filaments or beards about its mouth, and the coverings of the gills are armed with several prickles. Its head also has several prickles about it, and the wounds they make are said to be very venomous. The fish is however eaten, and accounted very well tasted. *Gesner*, de Pisc. p. 1017.

SCORTIUM, among the Romans, a measure of capacity of a round form, which used always to be heaped. *Pitisc.* Lex. Antiq. in voc.

SCORZONERA, in botany, the name of a genus of plants, the characters of which are these. The flower is of the semiflosculous kind, being composed of a number of semiflosculès standing on the embryo seeds, and contained in one general oblong cup. The embryos usually ripen into seeds, which are covered with a sort of coat or husk, and are winged with down.

The species of *scorzonera*, enumerated by Mr. Tournefort, are these. 1. The *scorzonera* with broad sinuated leaves. 2. The *scorzonera* with broad sinuated leaves, and bitter roots. 3. The double flowered *scorzonera* with broad sinuated leaves. 4. The Dutch broad leaved *scorzonera*. 5. The *scorzonera* with nervous leaves. 6. The low *scorzonera* with broad nervous leaves. 7. The common narrow leaved *scorzonera*. 8. The lower narrow leaved *scorzonera*. 9. The narrow leaved *scornozera* with little roots. 10. The narrow leaved *scorzonera* with bluish flowers. 11. The thick leaved Montpelier *scorzonera*. 12. The dusty flowered marsh *scorzonera*. 13. The *scorzonera* with jagged leaves. 14. The *scorzonera* with capillaceous leaves. 15. The plantain leaved Portugal *scorzonera*. 16. The grass leaved Portugal *scorzonera* with pale yellow flowers. *Tourn.* Inst. p. 476.

The root of this plant is used in medicine, and is esteemed an alexipharmic and sudorific. It is given in malignant fevers, and is by some recommended in epilepsies, vertigoes, and disorders of the womb; but it is not frequently prescribed in the present practice.

SCOTAL, or SCOTALE, is used where any officer of a forest keeps an alehouse within the forest, by colour of his office causing people to come to his house, and there spend their money, for fear of his displeasure. We find it mentioned in the Charter of the Forest, cap. 8. *Nulus forestarius faciat* scotallas, *vel garbas colligat, vel aliquam collectam faciat, &c. Manwood*, 216.

The word is compounded of *scot* and *ale*, and by transposition of the words, is otherwise called *aleshot*. Terms of Law. *Blount*, *Cowel.*

SCOTER, in zoology, the name of a species of duck, called also in some places the *black diver.*

It is nearly of the size of the common duck, but of a rounder body, and is all over of a deep shining and beautiful black; in some the shoulder feathers are of a yet deeper black than the rest; and in others there is a slight admixture of greyishness in the middle of the breast. The wings are black, without any variegation, and the beak is black, but has a little yellowness near the nostrils: the feet also are black. It is very common on the shores of Lancashire, and some other counties. It lives only about salt waters, and is a very great diver. *Ray's* Ornitholog. p. 80.

SCOTINUS, in botany, the name of a shrub called by the Latins *cotinus*, and *cotinus coriaria*, to distinguish it from the *cotinus*, κότινος, of the Greeks, which was the *oleaster*, or wild olive.

The Italians call the *cotinus coriaria* sometimes *scotinus*, and sometimes *scotanus*; the latter word seems an erroneous way of writing the former, which is only the Roman name of the same tree, with an *s* put before the first letter: and this is very common with the Italians, in their adopting Latin words; what the Romans called *phalangium*, they call *sphalangio*; what they called *conchylium*, these call *scongiglio*; and so of a number of other words.

SCOTODINOS, a term used by medical writers to express a vertigo, or dizziness of the head, attended with a dimness of sight.

SCOTOMA, a word used by some in the same sense as *scotodinos*, to express a vertigo with dimness of sight.

SCOUP *duck*, in zoology, the name of a species of duck, somewhat smaller than the common duck, and of a strange diversity of colours, even in the different birds of the same species, insomuch that it is not easy to find any two perfectly alike in a flock of forty or fifty. The beak is blue, and its most general colours are these: the head, and part of the neck, are of a greenish black; the lower part of the neck has some whiteness, and the breast is black; the belly is white, with an admixture of yellow in its lower part, and near the anus it becomes black; the upper part of the neck is of a sooty black; the middle of the back is white, variegated with dusky brownish lines, and the rump and tail are brown, as are also the wings, but these have some transverse streaks of white. The tail is not above two inches long; the legs are bluish. *Ray's* Ornithology, p. 279.

SCRATCH, in the language of the salt-workers of our country, the name of a calcarious earthy or stony substance, which separates from sea water in boiling it for salt.

This forms a thick crust in a few days on the sides and bottoms of the pans, which they are forced to be at the pains

of taking off once in a week or ten days, otherwife the pans burn away, and are deftroyed. See SALT.

This is no other than the fame fubftance which crufts over the infides of our tea-kettles, and is truly a fpar, fuftained more or lefs in all water, and feparable from it by boiling. The fhells of fea fifh have great affinity in their fubftance and nature with this, both being powerful alkalis, and both eafily calcining into lime.

The *magnefia alba*, fo celebrated in Germany for its mild purgative and alkaline virtues, feems very nearly allied to this earth; and it is probable, according to Hoffman, that the purging virtues of many fprings are owing to the quantities they contain of this fubftance.

SCRATCH *pans*, in the Englifh falt-works, a name given to certain leaden pans, which are ufually made about a foot and half long, a foot broad, and three inches deep, and have a bow, or circular handle of iron, by which they may be drawn out with a hook, when the liquor in the pan is boiling. See SALT.

The ufe of thefe *pans* is to receive a calcarious earth, of the nature of that which incrufts our tea-kettles, which feparates from the water in boiling; this fubftance they call *fcratch*; and thefe *pans* being placed at the corners of the falt pan, where the heat is leaft violent, catch it as it fubfides there.

SCREW (*Cycl.*)—SCREW, in the manege. See SPLENT and THOROUGH-*fplent*.

SCREW-*fhell*, the Englifh name of the *turbo*. See the article TURBO.

SCRIPTULUM, among the Romans, the twenty fourth part of an ounce, and equal to two *oboli*. See the article OBOLUS, *Cycl.*

SCRIPTULUS, a word ufed by fome inftead of *fcrupulus*, a fcruple, or weight of twenty grains.

SCROFANELLO, in zoology, a name by which fome have called a fmall fifh of the Mediterranean, more ufually known by the name of the *fcorpæna*. *Salvian*, de Aquat. p. 94. See SCORPÆNA.

SCROPHULARIA, *figwort*, in botany, the name of a genus of plants, the characters of which are thefe. The flower confifts of one leaf, and is of a fort of globofe form, open at the mouth, and divided as it were into two lips, the upper of which has two fmall leaves under it. The piftil arifes from the cup, and is fixed in the manner of a nail to the hinder part of the flower, and afterwards becomes a fruit or capfule, of a roundifh but pointed figure, divided by an intermediate feptum into two cells, and containing fmall feeds affixed to a placenta.

The fpecies of *figwort*, enumerated by Mr. Tournefort, are thefe. 1. The common, or knobby rooted *figwort*. 2. The great hairy *figwort*. 3. The great *figwort* with green ftalks and leaves. 4. The great water-*figwort*, commonly called *water-betony*. 5. The leffer water *figwort*. 6. The yellow flowered *figwort*. 7. The nettle-leaved *figwort*. 8. The baum-leaved *figwort*. 9. The betony-leaved *figwort*. 10. The fhrubby *figwort* with thick leaves, like in fhape to thofe of teucrium. 11. The fmooth elder-leaved Spanifh *figwort*. 12. The great hairy elder-leaved Portugal *figwort*. 13. The roundifh thick and black leaved *figwort* with pale yellow flowers, and very turgid feed veffels. 14. The fern-leaved *fcrophularia*, or broad leaved dog's rue. 15. The fhining ftone *figwort* with laferwort leaves. 16. The narrow leaved *figwort*, commonly called *dog's rue*. 17. The leffer dog's rue *figwort*. 18. The vervain-leaved fhrubby Portugal *figwort*. *Tourn.* Inft. p. 167.

The root of *fcrophularia* is efteemed externally as a remedy for the piles and the king's evil. It is generally made into an ointment for thefe purpofes; but fome give it alfo internally in diet drinks.

This root is of a very fingular figure, by which it is eafily diftinguifhed at fight from all other medicinal roots. It is ufually of the thicknefs of a man's finger, or more, of an oblong figure, nearly as thick at the one end as the other, and full of protuberances on the furface, refembling a kind of little kernels; and between there are a great many fibres, which ftrike deep into the ground. The root itfelf has no great fmell, but its tafte is fomewhat acrid and difagreeable.

SCROTUM (*Cycl.*)—Many authors have given accounts of the diftemperatures of this part, of various kinds, impeding the intent of the propagation of the fpecies, but one of the moft remarkable of thefe, is the exceffive growth of that part, as well in length as in breadth and thicknefs. Securgius, in his *Spermatologia*, gives an account of a perfon, whofe *fcrotum* grew to fuch a fize, that it reached down to his knees, and the penis was fo wholly loft in it, that the paffage for the urine was fcarce vifible, and feveral orifices were made by a fharp humor ouzing out of it in different places. The perfon lived a long time with it in this condition, and ufed to fupport it by a bandage worn acrofs the fhoulders.

The author gives alfo an account of another *fcrotum* of this kind, which being at length taken off, partly by a mortification, and partly by the operation of a furgeon, was replaced again by nature in the fame unufual fize.

SCRUTATORES, among the Romans, certain officers, or fervants, whofe bufinefs it was to fearch every body that came to falute the emperor, in order to difcover if they had any kind of arms concealed about them. They were firft inftituted under the emperor Claudius. *Pitifc.* in voc.

SCULION, in ichthyology, the name given by Ariftotle, and many other of the antient writers, to the fifh called by later authors *catulus*, and *catulus major*, and in England the *bounce*. It is a fpecies of the fqualus, called by Artedi the reddifh variegated *fqualus* with the pinna ani placed in the middle, between the anus and the fin of the tail. See the article SQUALUS.

SCULPONEÆ, among the Romans, a kind of fhoes worn by flaves of both fexes. Thefe fhoes were only blocks of wood made hollow, like the French *fabots*.

SCUMA, a word ufed by fome of the chemifts for *fquamma*, the fcales of any metal, and particularly applied to the flakes flying off from hot iron under the hammer.

SCURFF, in zoology, an Englifh name for a fpecies of falmon, called alfo in fome places the *bull-trout*. It never grows to any great fize, and differs plainly from the falmon of the common kind in this, that its tail is even, and not forked. Its head is fhort and thick, and its flefh is lefs red than that of moft of the falmon kind. *Willughby*, Hift. Pifc. p. 193.

SCURRA, in zoology, a name by which the antients have called the *monedula*, or common jackdaw. *Ray's* Ornithol. p. 85.

SCURVOGEL, in zoology, the name of an American bird, called by fome the *nhender-apoa*, and by the Brafilians *jaburuguacu*.

It is of the crane kind, or nearly approaching to that genus. Its beak is large, feven or eight fingers breadth long, rounded, and fomewhat bent upwards at the end. In the fummit of the head he has a fort of boney crown, of a mixed greyifh and whitifh colour. Its neck is confiderably long, and both that and the head are deftitute of feathers, and are only covered by a fquammofe naked fkin. It is about the fize of the ftork, and has a fhort black tail; all the reft of the feathers are white, except that the long wing feathers are blackifh, with fomewhat of a purplifh glofs. When the fkin is taken off, it is dreffed feveral ways, and is a very delicately tafted bird. *Ray's* Ornitholog. p. 202.

SCURVY (*Cycl.*)—There are fome who derive all difeafes from the *fcurvy*, which indeed muft be allowed to create, or mimic moft other maladies. Boerhaave tells us it produces pleuretic, colic, nephritic, hepatic pains, various fevers, as hot, malignant, and intermitting, dyfenteries, faintings, anxieties, dropfies, confumptions, convulfions, palfies, fluxes of blood; in a word, it may be faid to contain the feeds and origin of almoft all diftempers. A cachexy, or ill habit, is much of the fame nature with the *fcurvy*. It is fuppofed by phyficians, that the immediate caufe of the *fcurvy* lies in the blood, the fibrous part of which is thick, and the ferum too thin and fharp; and that hence arifes the great difficulty in the cure, becaufe in the correcting of one part, regard muft be had to the other. It is well known how extremely difficult it is to cure an inveterate *fcurvy*; how many *fcorbutic* patients have grown worfe by an injudicious courfe of evacuations; how many are even rendered incurable by the treatment of inconfiderate phyficians; and how difficult, tedious, and uncertain the cure is, in the hands even of the beft, who are obliged to ufe fuch variety and change of medicines, in the different ftages of that malady; which neverthelefs may be cured, fays the Bifhop of Cloyne, by the fole, regular, conftant, copious ufe of tar-water. In the cure of the *fcurvy*, the principal aim is to fubdue the acrimony of the blood and juices; but as this acrimony proceeds from different caufes, or even oppofite, as acid and alkaline, what is good in one fort of *fcurvy* proves dangerous, or even mortal, in another. It is well known, that hot anti-fcorbutics, where the juices of the body are alkalefcent, increafe the difeafe; and four fruits and vegetables produce the like effect in the *fcurvy* caufed by acid-acrimony. Hence fatal blunders are committed by unwary practitioners, who, not diftinguifhing the nature of the difeafe, do frequently aggravate, inftead of curing it. The bifhop fays, if he may truft what trials he has been able to make, this water is good in the feveral kinds of *fcurvy*, whether acid, alkaline, or muriatic; and he believes it the only medicine that cures them all, without doing hurt in any. In a high degree of *fcurvy* a mercurial falivation is looked on by many as the only cure; which, by the vehement fhock it gives the whole frame, and the fenfible fecretion it produces, may be thought to be more adequate to fuch an effect: but the diforder, occafioned by that violent procefs, it is to be feared, may never be got over. The immediate danger, the frequent bad effects, the extreme trouble, and nice care attending fuch a courfe, do very defervedly make people afraid of it. And though the fenfible fecretion therein be fo great, yet in a longer tract of time the ufe of tar-water may produce as great a difcharge of *fcorbutic* falts by urine and perfpiration; the effect of which laft,

though not so sensible, may yet be greater than that of salivation; if it be true, that insensible perspiration is considerably more than all the rest of the sensible secretions together. See TAR-*water.*

For the cure of the *scurvy* some have proposed, that the patient should be put into a warm or hot bath, till a sweat is moderately raised, and then immediately taken out and immersed into cold water. *Morgan*, Mech. Pract. of Phys. p. 354. ap. Med. Eff. Edinb.

SCURVY-*grass*, *cochlearia*, in medicine, is a powerful attenuant and resolvent; and on that principle is an excellent medicine in all diseases arising from a viscid state of the fluids, and particularly in the *scurvy*. The best way of taking it, is to eat the whole herb by way of sallad.

The *scurvy*, however, is a disease so various, that the same medicine cannot be good for all the kinds. Accordingly *scurvy-grass* proves hurtful, where the *scurvy* is attended with a redness in the face, palpitations of the heart, frequent feverish heats, head-achs, purgings, and the like; in all which, acrid medicines of any kind do harm. See the article COCHLEARIA.

SCUTARIUS, among the Romans, beside its ordinary signification of a shield-maker, was used to denote one of the emperor's life-guards, because their whole body was covered with armour. *Pitisc.* in voc.

SCUTELLARIA, in botany, a name given to a species of *cassida*. See CASSIDA.

SCUTHINON, in botany, a name given by the antient Greeks to a yellow wood, called also *thapsum*, *chrysoxylon*, and *scythicum lignum*. It was of a beautiful yellow colour, and was used in dying and in colouring the hair yellow, which was the favourite colour of that time.

The same authors have sometimes also called it *cythinon*, or *cuthinon*: this is only the former word with the initial *s* taken away, as it was common with them to do in regard to many words; thus they called the smilax *milax*, the smaragdus *maragdus*, and so of many more.

SCUTTLE-*hatch*, in a ship, the little hatch that covers the *scuttle*. See HATCH.

SCUTUM, in natural history, the name of a genus of the *echini marini*, the characters of which are; that it is a shell of an irregular figure, which on the lower part represents, in some measure, a shield; on the superficies it has the shape of a five-leaved flower; its mouth is in the middle of the base, and the aperture for the anus at the edge. See Tab. of Testaceous Animals, N° 6 and 7.

Of this genus of the eschini there are two kinds, the angular and the oval. The angular kind has its circumference notched into corners; on its back it has the cinquefoil leaf with very turgid marks, the lines being all crenated also at the edges, so that it in some measure represents the flowers of the gourd kinds when open. The aperture of the anus is at the broader side of the circumference.

The oval kind is a shell of a tolerably regular oval figure, with the cinquefoil mark upon its back, made up of leaves like those of the olive, but split as it were at the extremities. The mouth in this species is in the middle, the anus in the edge, and the base is a little hollowed.

Of the first of these kinds, the angular *scuta*, there are only two known species: the first a lower flattish kind, and the second a more elevated one.

Of the second, or the oval *scuta*, there are three known species. 1. A kind made up of extremely small granulose circles. 2. A hollow based one shielded like the tortoise, and with a pentagonal aperture for the mouth. And 3. an echinated one with a very high top, and a slight sulcus, or furrow, on that part where the anus is. *Klein*'s Echnod. p. 28.

SCUTUM, in pharmacy, a name given to a solid stomachic topic, whether made in form of a bag, with medicinal ingredients sowed in it, or of a plaister. It is always fashioned into the shape of a shield. The plaisters, for this purpose, were used to be made of the warm stomachic gums, and the bags were filled with the warm aromatic powders; and they were worn to warm and strengthen the stomach, correct a cold intemperature, and promote digestions, and prevent vomiting. The patella, or knee pan, is also sometimes called by anatomists *scutum*.

SCYBALA, a term used by the antient physicians to express the excrements of the intestines, hardened into lumps while in the body.

SCYBELITES, a term used by the antients to express a sort of must, or juice of the grapes, which distilled from them spontaneously without pressing.

SCYLACION, a word by which the antients expressed the flesh of puppies, which they recommended as of great service in many chronic cases.

SCYLDWIT, in our old writers, a mulct or fine for any fault. Leg. Hen. I.

It comes from the Saxon *scilde*, i. e. *delictum*, and *wite*, i. e. *pœna*. *Blount.*

SCYMNUS, in ichthyology, a name used by Ælian, Appian, and many other of the old Greek writers, for the fish called *sculion* by Aristotle. This is a species of the squalus, called by Artedi and others the *squalus* with the pinna ani placed in the midst, between the anus and tail; the *catulus vulgaris*, and *catulus major* of authors. See the article SQUALUS.

SCYPHUS, among the Romans, a very large kind of drinking cup. The *scyphus* was called the cup of Hercules, as that of Bacchus, *liberi patris*, was named *cantharus*. *Pitisc.* in voc. See the article CANTHARUS.

SCYRA, in our old writers, a fine imposed upon such as neglected to attend the *scyregemot* court, which all tenants were bound to do. *Blount*, *Cowel.*

SCYRIUM *marmor*, a name given by the antients sometimes to a white, and sometimes to a yellowish marble, both used in the public buildings of the Romans, but seldom in statuary, not being capable of a high polish.

SCYTALE, in zoology, the name given by the antients to a species of serpent, which was very long and thin, and equally big all along the body, so that the tail was not easily distinguished from the head.

SCYTHÆ, Σκυθαι, among the Athenians, a designation sometimes given to the officers, more usually called *lexiarchi*.

They had the name *scythæ*, because they were often natives of Scythia who were chosen *lexiarchi*, as being brawny and sturdy fellows. See LEXIARCHI.

SCYTHARION, in botany, a name given by the antient Greek writers to a tree, whose wood was of a fine yellow colour, and was used in those early times to dye things yellow; it was called also *Scythicum lignum*, from its country, and *chrysoxylon*, or golden wood, from its fine yellow colour. It has been supposed that this was the same with the *cotinus coriaria* of the Romans; but this is an erroneous conjecture, since the wood of this tree dyed a yellow colour, and that a brownish red, or a clear and pure red, according as the infusion was made more or less strong. This *scytharion*, therefore, could not be the same with the *cotinus*, but it certainly is the same with the *thapsum* of the Greeks. See CHRYSOXYLON.

SCYTHIAN, a word used very often in the old Greek writers on the materia medica, to distinguish the peculiar sort of gum, or other drug, brought from that place. The *Scythian* and Indian drugs have been by many supposed different kinds of the same medicine; but this is an error, for it appears very obvious, on comparing the writings of Galen, Aëtius, Ægineta, and other of the later writers among the Greeks, with those of Dioscorides, Theophrastus, and the other old ones, that the words *Scythian* and Indian mean the same thing, and that what the old writers have called Indian, these have called *Scythian*.

The meaning of this is, that those things were called *Scythian*, which were brought from the country of Indoscythia, or that part of *Scythia* which lay at the ostia of the river Indus: but it is to be observed, that though the later Greek writers mean this by their term *Scythian*, yet the word is used in a very different sense by the Arabians, Avisenna, Serapio, and others; and that wherever they mention a drug under the name of *Scythian*, they mean that it comes from the northern parts of *Scythia*, on the confines of Europe. These authors having understood of this *Scythia*, what the Greek writers have said of the other, have made no small errors in regard to the history of drugs, having given bdellium, and many other gums, the produce of only the *Scythia* of the Greek medical writers, to the frozen *Scythia* before-mentioned.

SCYTHICUM *lignum*, in botany, a name given by the antients to a tree, called also *scytharium* by the later writers of the Greeks. This is by some supposed to be the same with the *cotinus* of the antients used in dying.

The Greeks called the *oleaster*, *cotinus* indeed, but that is not meant as the shrub supposed to be the same with the *Scythicum lignum*, but the *cotinus Romanorum*, or, as those people expressed it, *cotinus coriaria*.

This however seems to be an error; for the *cotinus coriaria* was used to dye yellow, whereas the *Scythicum lignum* was used for a fine pale yellow, or citron colour, and was thence called *chrysoxylon*, the golden wood, or wood dying a gold colour.

Pliny says that the *cotinus coriaria* dyed things to the colour of the fine conchs, that is, to a fine bright flesh colour; and Anguillara tells us, that the *scotano* of the Italians, which is the same with the *cotinus coriaria* of the Romans, dyes woollen things to a very agreeable red colour. The words of Pliny are, that it dyes things *conchylii colore*. These have been understood as expressing the colour of the purple fish, or murex, which is a kind of shell fish, and whose colour is a true purple; in this sense the colour would not be the same with that yielded by the modern *scotano*: but this is not the sense of Pliny, for he often mentions the *conchylius color* as a kind of red, and in many places carefully distinguishes it from the purple colour yielded by the murex; and it seems, according to him, to be the fine pale red, which we see so beautiful in the mouths of the great conchylia, which our collectors of shells call *conchs*. See the articles SCOTANO, and CONCHYLIUS.

SEA (*Cycl.*)—The *sea* differs in saltness in different parts; it is, in general, observed, that in hottest climates the water is saltest. When

When salt water freezes, it hath been thought to let fall all its salt; the ice of *sea* water, and the water melted from it, tasting fresh, and being good for boiling meat and pease in. Captain Middleton, being in Hudson's streights in July 1738, took ice from under the surface of the *sea*, which he melted till he got forty quarts of water; these he evaporated to dryness, and out of that quantity had only six ounces of salt, or about $\frac{1}{213}$. Philos. Trans. N° 461. sect. 13.

The ascent of the *sea* water, for the formation of springs by a subterranean circulation of its water to their sources, has been a great objection with many against the system of their being formed of the *sea*; but Dr. Plot has observed, that there are many ways by which the water may ascend above its own level. 1. By the means of subterranean heats. 2. By filtration. 3. By the unequal height of several *seas*. 4. By the distance of the center of magnitude from the center of gravity in the terraqueous globe. The superficies of the Pacific *sea* is said to be farther from the center of gravity, than the top of the highest hill on the adverse part of the globe. And 5. by the help of storms.

The *sea* water actually ascends above its own level in coming into wells, whose bottoms lie higher than the surface of the sea at highwater mark. *Plot*, de Origine Font.

General motion of the SEA. Mr. Dassie of Paris, in a work published about sixty years ago, has been at great pains to prove that the *sea* has a general motion, independent of winds and tides, and of more consequence in navigation than is usually supposed. He affirms that this motion is from east to west, inclining toward the north, when the sun has passed the equinoctial northward, and that during the time the sun is in the northern signs; but the contrary way, after the sun has passed the said equinoctial southward; adding, that when this general motion is changed, the diurnal flux is changed also: whence it happens, that in several places the tides come in during one part of the year, and go out during the other; as on the coasts of Norway, in the Indies, at Goa, Cochinchina, &c. where, while the sun is in the summer signs, the *sea* runs to the shore, when in the winter signs, from it. On the most southern coasts of Tonquin and China, for the six summer months, the diurnal course runs from the north with the ocean; but the sun having repassed the line toward the south, the course declines also southward. Philos. Trans. N° 135.

Bason of the SEA, *fundus maris*, a term used by geographers, and other writers, to express the bottom of the *sea* in general.

Our honourable Mr. Boyle is the first who has written any thing on this part of the globe, and he has given us a treatise expressly upon it; but this only gives an account of its irregularities, and unequal depths, and is founded on the observations communicated to him by mariners, and people of too little curiosity to be depended upon for great discoveries.

The ingenious Count Marsigli has, since his time, given us a much fuller account of this part of the globe, in a great part from his own experiments in many places, particularly along the coasts of Provence and Languedoc.

The entire bason of the *sea* is of such immense extent, and covered in many places with such an unfathomable depth of water, that it is not to be expected that it can be traced in every part; but as the whole may be guessed at, from some part of it, and as its general figure is of no consequence in a search of this kind, the observations of this curious author are of great value, in forming a judgment of the whole. *Marsigli*, Hist. de la Mer. p. 4.

The materials, which compose the bottom of the *sea*, may very rationally be supposed, in some degree, to influence the taste of its waters; and Marsigli has made many experiments to prove, that fossile coal, and other bituminous substances, which are found in plenty at the bottom of the *sea*, may communicate in great part its bitterness to it. We are not, however, to judge hastily, that there are not so many beds of these at the bottom of the *sea*, as would be necessary for such a purpose, or to judge too hastily against the existence of any other substances there, because we do not find proofs of them by the plummet, which in founding brings up other substances, and not these; for the true bottom of the *sea* is very often covered and obscured from us by another accidental bottom, formed of various substances mingled together, and often covering it to a considerable depth.

The entire gulf of Lyons, situated between Cape Quiez in Rousillon, and Cape Croisit in Provence, forms a bank above the surface of the water at the shore, of the exact and perfect figure of an arch; and within this there is formed another such arch, making the bottom of the *sea* in that place for a very great way from shore, which is of different depths in various places, but usually between sixty and seventy fathom. See SHORES.

It is a general rule among sailors, and is found to hold true in a great many instances, that the more the shores of any place are steep and high, forming perpendicular cliffs, the more deep the *sea* is below; and that on the contrary, level shores denote shallow *seas*. Thus the deepest part of the Mediterranean is generally allowed to be under the height of Malta. The observation of the strata of earth, and other fossils, on and near the shores, may serve to form a very good judgment, as to the materials which are found in its bottom. The veins of salt and of bitumen doubtless run on the same, and in the same order in which we see them at land; and the strata of rocks, that serve to support the earth of hills and elevated places on shore, serve also, in the same continued chain, to support the immense quantity of water in the bason of the *sea*. It is probable also that the veins of metals, and of other mineral substances, which are found in the neighbouring earth, are in the same manner continued into the depths of the *sea*. The particles of metals, in this case, are probably carried off into deep water, and sunk among the softer matter of the bottom, but some of the lighter minerals seem to have given colour to those beautiful crusts, which are found upon many *sea* plants, and which lose their lustre in the drying. The subterranean rivers, and currents of water, make great changes in what would be the natural surface of the bottom of the *sea*, where they arise, each having a peculiar bason of its own. We are informed by numerous instances of subterranean currents, and as we see them break out in rivers on the surface of the earth in some parts, so in others we may be well assured that they break up the bottom of the *sea*, and empty their fresh waters into the salt mass.

In this case, the rushing up continually of such a body of water makes a roundish cavity, and its running some one way lengthens and carries on that cavity, till by degrees it is lost, as the fresh water by degrees becomes blended with the salt. Thus every river, that arises in the bottom of the *sea*, alters the form of its surface, and makes a bason for itself, in which it runs a considerable way. Many *seas* near the shore, and when the water is tolerably clear, shew the traces of these currents to the naked eye from the surface, and the water taken up from them is found more or less fresh. *Marsigli*, Hist. de la Mer. p. 13.

The coral fisheries have given us occasion to observe, that there are many, and those very large, caverns or hollows in the bottom of the *sea*, especially when it is rocky; and that the like caverns are sometimes found in the perpendicular rocks, which form the steep sides of those fisheries. These caverns are often of great depths, as well as extent, and have sometimes wide mouths, equal to their largest diameter in any part, but sometimes they have only narrow entrances into large and spacious hollows. It is the common opinion of the people about the place, that these caverns are prepared by nature for the circulating of the *sea* water; but that operation, however necessary, may be performed as well without, as with these caverns, and they seem in reality to be only accidental.

We daily meet with immense hollows and caverns, naturally made in rocky mountains; and as this part of the bottom of the *sea* is almost all rock, and its sides of the same nature, it is no wonder that the same accidents should happen, and like hollows be found, though with no particular intent of providence in their use. Nay there is this farther reason to expect them in the rocks buried under the *sea* than in those in hills, that the latter are in a state of rest and quiet, whereas the former are in continual reach of water, which will insinuate itself into every crack or crevice nature has left in them, and may be easily supposed to have burrowed its way in a small hole made by nature, till it has formed of it a very large one.

It seems plain from the whole, that the bason of the *sea* was at the creation, or at its second formation after the universal deluge, covered with, or composed of the same substances, as the surface of the rest of the earth is, that is of rocks, clay and sand, and other such substances. The common observations of seamen seem indeed to make against this opinion, but they may be easily solved, so as not to overthrow it. The plummet which they let down in founding, usually brings up with it a matter composed of mud, tartarous incrustations, or of dead weeds and broken shells, or numbers of various bodies of this kind, cemented together into a firm mass by some sparry or tartarous matter, deposited from among the water, and agglutinating them together: these form an artificial bottom, covering the natural one; but it is easy to see, that such a crust or coat as this must needs have been formed over the true bottom, in places where numbers of animals and vegetables are produced, and decay again, and where the waters being at rest have time to deposit their stony matter, in the same manner as the waters of several of our petrifying, or rather incrustating springs do. And that these decayed substances, and this stony matter, falling to the bottom together, and there lying undisturbed, must necessarily have formed just such a crust as is found; and the natural bottom of the *sea*, whether of stone, of sand, or of clay, must be covered by such accidental concretions, and that probably to such a depth, that it is not easy now to break through it.

There are places however where, by some accidents, this sort of adventitious crust either has never been formed, or else has been removed. In these places we find the natural

tural bottom, as described, that is of the same nature with the strata in the body of the earth. The simile the Count Marsigli has made, between the bason of the *sea* and a cask of wine, is very expressive and just. When wine has been a long time kept in a cask, the whole internal surface of that cask is so covered and encrustated over with tartar, that it seems within to be really composed of it; yet as we know that this cask is of wood, we are very certain that the true inner surface of it is of the same texture and nature with the tree from which it was cut, though we cannot get off the accidental surface formed by the liquor kept in it, and wholly covering it.

We very frequently meet with fine and pure sand at the bottom of the *sea*, and in these places are apt to believe that we certainly have the true and original bottom, but this is rather to be looked on as a probability than a certainty; and where the sand is more than ordinarily fine, there is always reason to suspect that the course of some subterranean river has brought it there, by opening into the *sea* in this part; and that this is one of those particular basons, which these rivers form to themselves within the bason of the *sea*, and which continue only to a small distance from their source. *Marsigli*, Hist. de la Mer. p. 15.

The bottom of the *sea* is covered with a variety of matters, such as could not be imagined by any but those who have examined into it, especially in deep water, where the surface only is disturbed by tides and storms, the lower part, and consequently its bed at the bottom, remaining for ages perhaps undisturbed. The soundings, when the plummet first touches ground on approaching the shores, gives some idea of this. The bottom of the plummet is hollowed, and in that hollow there is placed a lump of tallow; this being the bottom of the lead, is what first touches ground, and the soft nature of this fat receives into it some part of those substances, which it meets with at the bottom: this matter, thus brought up, is sometimes pure sand, sometimes a sort of sand made of the fragments of shells, beat to a sort of powder, sometimes it is made of a like powder of the several sorts of corals, and sometimes it is composed of fragments of rocks; but beside these appearances, which are natural enough, and are what might very well be expected, it brings up substances which are of the most beautiful colours. Things of as fine a scarlet, vermillion, purple, *&c.* as the finest paint could make them, and as yellow as a solution of gamboge, are common; and sometimes, though not so frequently, the matter brought up is blue, green, or of a pure snowy whiteness. These coloured matters sometimes seem to have made up the whole bottom or mass of the surface, but more usually they have been formed upon other things, as upon the mud, or upon larger pieces of shells, corals, and the like, in the manner of tartarous crusts, and those in some degree resembling the crustaceous coats of some of the *sea* plants. The colours of these substances are not merely superficial and transient, but many of them are so real and permanent, that they may be received into white wax melted, and poured upon them, or kept in fusion about them; and when thus examined, they seem as if a proper care might make them of great value, as paints of the finer kinds, where little is to be used.

The same coloured matters that thus coat the substances, found at the bottom of the *sea* in these places, are also sometimes found extended over the surface of *sea* plants of the harder kind, which grow in deep water. They are always, in this case, in a sort of liquid form, being lodged within, or embodied among a sort of jelly or glue of a transparent substance, which in these cases perfectly coats over the whole plant. In this state it gives the naturalist, who is present at the fishing up his treasures, a transient prospect of a very elegant kind; but this vanishes while he admires it. A piece of coral, or other hard *sea* plant, thus coated over, appears, as it rises to the surface of the water, of a delicate green, blue, or purple, but when taken above water, it is found that this fine colour is only in the coat of glue or jelly which covers the plant: as soon as this is wiped off, the colour is carried away with it, and the coral shews its own native tinge; and it is to no purpose to attempt the preserving it, by suffering this glue to dry upon the plant, for the colour flies away by degrees, as the moisture evaporates, and the coral or plant, whatever it be, is only so much the less beautiful, than it naturally would have been, as it is covered with a dry yellowish dirty looking horny matter. These are beauties in the submarine plants, therefore, which can be only seen by those who venture out, in order to take them up.

The small quantities of these elegant colours, which we thus find spread over the surfaces of plants and other bodies, as we approach deep water, may give a rational idea of what we should find, were we able to examine the bottoms of the *sea* in its deep and unfathomable recesses. It is easy to conceive, that in these places we should find great quantities of the most beautiful substances. *Marsigli*, Hist. Phys. de la Mer.

Dead SEA. Dr. Perry made several experiments on the water of the *Dead sea*, in order to find what particles it contained. Upon infusing some scrapings of galls in it, it becomes of a bright purple colour, but that not till it has stood a considerable time. On adding oil of tartar *per deliquium* to it, it becomes turbid, and looks as if globules of fat were fluctuating in it; this unctuous matter, upon its long standing in repose, comes together in form of a sediment at the bottom. On pouring spirit of vitriol into it, it deposits a milk-white greasy sediment, which, after standing twelve hours, occupies about one fifth part of the liquor. On putting a small quantity of saccharum saturni to it, it deposits a small quantity of a greyish powder. Being severally and separately mixed with a solution of sublimate, with spirit of sal armoniac, and with sugar of violets, it neither ferments, nor deposits any sediment, nor changes colour, except with the sugar of violets, with which it becomes green. It is highly saturated with salt, so that it is to common water in specific gravity, as five to four; and it has so acrid and styptic a taste, that on being held in the mouth, it constringes it in the manner of alum.

From all these experiments it appears, that this water is impregnated with a sort of an acrid and alkaline nature, and a matter partly of a sulphureous, partly of a bituminous nature. Philos. Trans. N° 462. p. 50.

SEA *adder*, an English name for a sea fish of the acus kind, called by Willughby the *acus lumbriciformis*.

It is a small fish of a cylindric shape, without scales, and of a greenish brown colour, with some admixture of a reddish yellow. The snout is long and hollow, and the mouth opens upwards at its end. The eyes are small, and their iris red. The gills are four on each side, but are covered by a membrane, and the whole body divided into rings like the common earth-worm. It is usually about three or four inches long, and of the thickness of a goose quill. It has but one fin, which is situated on the back. The anus is much nearer the head than the tail; and under the snout there is always a fleshy tubercle. The fish is common on the coast of Cornwall. *Willughby*, Hist. Pisc. p. 160.

SEA *breaches*, a term used by the farmers to express the overflowing of their low lands near the *sea* by the *sea* water.

Sea salt, moderately used, is a great improvement to all lands, but too much of it kills all sorts of vegetables, except such as nature has intended to live among it. The *sea* breaking in upon lands thus, injures them greatly. The owner is to stop the breach by which it entered with all possible diligence, and then trenches and drains must be cut through all parts of the land, to carry the salt water into some one low place, from which it may be emptied by means of an engine; or if it be small in quantity, it may be laded out by hand over the bank; or if yet less, the sun and winds may dry it away: but in either case, the place where it was suffered to rest must be covered with a large quantity of fresh earth, to take off from the too great saltness of the other; and the whole land should be plowed for three or four years, to let in the rains and air to freshen it. *Mortimer*'s Husbandry.

SEA *bream*, in ichthyology, the English name for the fish called by the generality of authors the *pagrus* and *phagrus*. According to the new system of Artedi, it is a species of the *spari*, and is distinguished by the name of the *red sparus* with the skin carried into a sinus at the roots of the back fins, and the pinna ani. See PAGRUS and SPARUS.

SEA *calf*, *vitulus marinus*, in zoology. See PHOCA.

SEA *cow*, the English name of the *manati*, a species of fish so different from all the other of the cetaceous tribe, to which it properly belongs, that Artedi, in his new system of ichthyology, allots it a peculiar generical name, which is *trichechus*.

It is called by Herrera *taurus marinus*, or the *sea bull*, and by others the *tachas* and *la donna*. The French call it *lamantin*, or *namantin*, and the Portuguese *pezze mouller*.

It may seem strange, that so ill shaped a creature as this should have given rise to the stories of the syrens and mermaids, the *sea* men and *sea* women, yet there is great reason to believe, that all the fabulous accounts of these monsters are owing to the seeing this animal raise its head and shoulders above the water. See SEA *man*.

SEA *crow*, in zoology, a name given by the common people of many counties of England to the *pewit*. See the article PEWIT.

SEA *devil*, in ichthyology, an English name for the *rana piscatrix*, or *lophius*. See RANA *piscatrix*.

SEA *fox*, an English name for a fish of the squalus kind, called also the *sea ape*; both names being given on occasion of the length of its tail in proportion to the body.

It is a very singular fish, and, according to the new Artedian system, is a species of *squalus*, distinguished by that author by the name of the *squalus cauda longiore quam ipsum corpus*.

The old Greek writers have called it *alopæcia*, and the later *vulpes marina*, and *simia marina*, whence the names *sea fox*, and *sea ape*. See the articles VULPES and SQUALUS.

SEA-*gate*, at sea. When two ships are aboard one another, by means of a wave or billow, the seamen say they *lie aboard one another in a sea-gate*.

SEA *green*. To make this colour in the glafs trade, the fineft cryftalline glafs only muft be ufed, and no manganefe muft be added at firft to the metal. The cryftal fritt muft be melted thus alone, and the falt, which fwims like oil on its top, muft be taken off with an iron ladle very carefully. Then to a pot of twenty pound of this metal, add fix ounces of calcined brafs, and a fourth part of the quantity of powdered zaffer: this powder muft be well mixed, and put into the glafs at three times, it will make the metal fwell at firft, and all muft be thoroughly mixed in the pot. After it has ftood in fufion three hours, take out a little for a proof; if it be too pale, add more of the powder. Twenty four hours after the mixing the powder the whole will be ready to work, but muft be well ftirred together from the bottom, left the colour fhould be deepeft there, and the metal at the top lefs coloured, or even quite colourlefs. Some ufe for this purpofe half cryftal fritt, and half rochetta fritt, but the colour is much the fineft when all cryftal fritt is ufed. *Neri's* Art of Glafs, p. 39.

SEA *gudgeon*, an Englifh name given to the fifh called by the generality of writers *gobius niger*, and the *gobius marinus*.
Artedi, who has made a genus of the *gobii*, excludes the common *gudgeon*, or *gobio fluviatilis*, from it, but he admits this fifh as a genuine fpecies of it.
Athenæus tells us of three kinds of *gudgeons*, the black, the yellow, and the white. This feems to have been very plainly the black *gudgeon* of that author. Salvian, in his figure of this fifh, has given three fins on the back, but it really has only two.

SEA *hen*, in zoology, a name given by fome to the *lomwia*, a webfooted bird, common on our coafts, and called the *guillemot*, or *kiddow*. See LOMWIA.

SEA *horfe*, the Englifh name of the *hippocampus*, a fpecies of the *acus*, according to the older writers, and one of the *fyngnathi* of Artedi. See thefe heads.
The many idle tales reported of this vaft amphibious creature, fuch as his method of bleeding himfelf when diftempered, his vomiting fire when enraged, and the like, have made people, in almoft all ages, defirous of feeing the animal. The Romans were fond of exhibiting it in their fhews of wild beafts, and the defcription Pliny gave of it from thence, was all the world knew of the creature for many ages. That author's account, however, of its feeding on grafs on the banks of the Nile, no way agrees with the teeth we find its mouth furnifhed with.
The fceletons of thefe animals, as rare as they are with us at prefent in their recent ftate, yet are found not unfrequently, in part at leaft, buried under ground, and that at great depths. The bones of the head are different from thofe of any other known animal, and when found in fome parts of France, had always puzzled the wits of the naturalifts there, who had in vain compared them with thofe of oxen, horfes, &c. but at length one of the heads of thefe animals being fent over to France, cleared up the whole difficulty. The two jaws of this weighed forty five pounds, and were two feet long, a foot deep, and a foot and half wide. It is eafy to conceive from this, that the accounts we have of the fize of the animal are not fabulous, thefe bones correfponding very well with them. Mem. Acad. Par. 1724.

SEA *loufe*, *pediculus marinus*, a name given to the Molucca crab. See SQUILLA.

SEA *man*. We have many accounts, even from authors of credit, of fomething refembling the human figure feen at *fea*, and fancy has carried them to fuch a height, that the truth of the defcription is loft in moft of them.
The fyrens, which we have accounts of even in Bartholin, and the *fea man*, or *homo marinus*, as it was called, feen and defcribed by Barchewitz, give the greateft credit to the ftory; but writers are fo fond of telling marvellous things, that great allowances are to be made in the reading.
The general defcription of the *fea man* is, that from the navel downwards the whole is only a fhapelefs lump of flefh, without any the leaft mark, either of limbs, fins, or tail. On the breaft there ftand two pectoral fins, which are each compofed of five bones or rays, refembling the human hand, and connected together by a membrane like the toes of a duck, or fome other water fowl's foot.
Thefe fins are what have the appearance of fomething human, and when feen about the bofom of a white bellied fifh, may be taken for hands with fhort arms, and the refemblance of a head is eafily fancied. Thefe fins are not peculiar to any one kind of fifh, but the manati, or *fea* cow, the rana pifcatrix, or lophius, and many others have them. It is probable from moft of the accounts we have, that the manati, or *fea* cow, is the creature, which being feen raifing its head above water at a diftance, and extending thefe pectoral fins, which are what it fwims with, has given rife to the idea of the upper part of a human figure.
As to the defcription of a fhapelefs lump of flefh making up the lower part of the animal, it feems too contrary to the courfe of nature in all other *fea* animals, to have any foundation in reality, and probably was only the invention of the defcriber, to make out what he did not fee above water.
It is true that Barchewitz takes great pains to prove that the *fea man*, or *homo marinus*, he defcribes, was a wholly different creature from the *fea* cow; but his defcription of it carries too little the air of any thing in nature, to meet with an eafy credit.
It is wonderful, that fo judicious a writer as Artedi fhould give any faith to the exiftence of fo ftrange a fifh as this, but he mentions it with a great air of diftruft, and wifhes a more perfect hiftory of it, if it any where exifts.
The public are often impofed upon by cheats, who fhew different things under the name of *fea men*, mermaids, and fyrens; but if we may judge of the generality of thefe creatures, thus fhewn by the lateft inftance among us, they are very wretched counterfeits indeed. This creature was faid to be a young mermaid, taken on the Acapulca fhore, and maintained its credit fo well in London, as to afford the proprietor a comfortable fubfiftence for ten months among us, though no other than a human fœtus of about eight months, with a hydrocephalus head, and with the two legs growing together, and covered by one common membrane. The toes of this fœtus were beat out into a refemblance of fins.

SEA *owl*, in ichthyology, a name given by many to that fifh, which we more ufually call the *lump fifh*, the *lumpus* of Willughby, &c. and the *cyclopterus* of Artedi, which fee.

SEA *pheafant*, in zoology, the name of a bird of the duck kind, but differing from all the other fpecies in the fhape of its tail; which has two long feathers, ftanding out beyond the reft, and terminating in a point. It is called more generally the *cracker*. See the article CRACKER.

SEA *plants*. Count Marfigli, who was at indefatigable pains to collect the various *fea plants* of feveral places, divides all thofe productions into three claffes.
The firft clafs contains the foft, or herbaceous ones; the fecond the ligneous ones, or fuch as are of a woody hardnefs; and the third, thofe which are of the hardnefs of ftone. Of the firft clafs are the algas, called *fea wracks*, the fucufes, or *fea oaks*, the *fea moffes*, or confervas, and the different fpecies of fpunges.
Of the fecond kind are thofe called *lythophyta* by the antients, as if their hardnefs approached to that of ftones. All thefe confift of two fubftances, a cortical and an internal: the cortical part, while in the *fea*, is foft, but in drying it becomes as hard as chalk, or thereabouts, eafily crumbling to pieces between the fingers; this is what deceived the antients into an opinion of its being of a ftony nature. The internal fubftance, properly fpeaking, feems more the nature of horn than of wood: if it is burnt, it throws out a fpume, or froth, like that which horns or feathers of animals yield in the fire, and their fmell in burning is of the fame kind. The branches of thefe *plants* are very pliable, bending in the manner of whalebone, and they give the fame refiftance to a knife in the cutting.
The ftony *plants*, which fhould properly be called the *lythophyta*, but which never are called fo, are the feveral fpecies of coral, madrepora, and the like. The madrepora differs from the coral, in having its furface pierced with almoft innumerable holes.
The algas are the only *fea plants* which have any roots, properly fo called; thefe therefore grow out of the foft bottom of the *fea*, as other plants out of the earth, but all the other *fea plants*, without exception, appear fixed upon hard and folid bodies, incapable of affording them any nourifhment; fuch as ftones, fhells, pieces of iron, of wood, &c. and fometimes on other *plants*; and they are not faftened to thefe fubftances by fibres paffing into, or furrounding them, but merely by a foot or pediment, capable of only fixing them down, not of drawing nourifhment from the fubftances, were there any there. From this obfervation the author concludes, that all the *plants* which have no roots may be properly faid to be all root, or to perform the office of roots in their whole fubftance, or that they take in nourifhment in every part by certain pores, which in many are vifible, and cover the whole furface.
This manner of receiving nourifhment, he alfo obferves, very well fuits their condition, fince they are always furrounded, on all fides, with that water by which they are to be nourifhed; whereas the plants, which grow at land, have only a part of them buried in the earth, from whence they are to be fupplied with the proper juices. The roots of land plants, therefore, have only the neceffary organs for receiving fupplies; whereas the *fea plants* he finds to be all over covered with fmall glandules, whofe office it is to receive and to convey, into the internal parts of the *plant*, the proper juices for its nourifhment, and thefe he obferves are, in general, of a glutinous and milky nature. The great difference between the land and *fea plants* is feen in this familiar inftance; a land plant will remain frefh for a long time, in all its parts, on one end of the ftalk only being plunged in water, but a *fea plant*, if part of it be out of water and part in, will always be frefh and vigorous in that part which is under water, while the part that is dry will wither and decay. It is eafy hence to fee, that the feveral parts of the land plants have connections with, and dependances on one another; whereas, in the *fea plant*, every part takes in its own

own nourishment, and lives and flourishes wholly independent of the rest.

After having gone through this general system, the author descends to several remarkable particulars. He mentions an instance of a fucus, whose stalk, when in its growing state, is a quarter of an inch in diameter, yet in drying shrinks up so much, as to be not thicker than a single thread. Another species, called by the fishermen the *sea orange*, from its resemblance to an orange in shape, he observes is properly a fucus; it has neither stalk nor branches, but consists wholly of this globular body; it is not a solid substance, but a membrane of about , of an inch in thickness, regularly distended into this shape, by being filled with *sea* water. All over the sides of this cavity there are fixed slender filaments, which traverse the whole, and probably receive nourishment from the water contained in the cavity, and distribute it to the several parts of the sides where they are inserted.

Another *sea plant* this author mentions, only appears in the shape of a bark; it affixes itself to the branches of the lythophyta, when they have lost their natural bark, and sometimes, in the same manner, coats and crusts over the surfaces of stones. When it is fresh, it is of a lively red, of the consistence of a mushroom, and about the thickness of the back of a common knife, and its external surface is full of small prominences, which contain a glutinous juice; round about these also there stand several yellow tubercles, which, with the red of the ground of the *plant*, make upon the whole a very beautiful appearance. Its under surface is perfectly smooth and glossy. This seems a much more remarkable *plant*, as to the manner of its vegetation, than those which grow on other plants at land.

The same author observes, that several of the spunges, when taken out of the *sea*, have a motion of the nature of a systole and diastole, which lasts as long as there remains any of the *sea* water in their cavities. Some of the *sea plants*, which while growing are as soft as the fucuses, yet when dried are as easily rubbed to powder between the fingers, as the bark of the lithophytons. There is one of the lithophytons, which carries so large a quantity of branches, that they make the resemblance of leaves; but as these leaf-like branches are all truly of the same nature with the rest of the *plant*, this is no exception to the general rule, that the lithophyta have no leaves. One of the species of lithophyton is naturally destitute of a bark, and is covered in the place of one with a glutinous substance, of the nature of varnish; this is most abundant at the foot. The whole *plant* is full of prickles, and these appear the most plainly on the summits of the branches, where this glutinous varnish is more thinly spread. On this part of the *plant*, also, there appear certain globules of a glutinous matter, when it is taken out of the water, which, when it is again plunged into it, spread themselves over the whole surface of the branches.

The madreporæ grow in the same places with the coral; they often hang pendulous from the hollow rocks, and often grow erect on the flat ones. They usually change colour when taken out of the water, and are of very different kinds and different degrees of hardness; many of them are as hard as common stones, and many others are so brittle, that it is scarce possible to touch them without breaking their branches.

The flowers of the thorny and naked lithophyton appear to be wholly like those of coral, and like them they are not found to contain any solid seed. Mem. de l'Acad. Par. 1710.

The many uses of the numerous *sea plants* to the system of the world are not yet sufficiently known. Among others, Dr. Lister has observed that they serve to render a great deal of the *sea* water fresh, and give it in mists to the clouds, whence it again falls on the earth. This is easily proved by experiment thus: if a quantity of *sea* water be put into a long glass body, and into it there be put a large and vigorous *sea plant*, such as the common *sea* wrack, and the head placed on the glass, and a receiver fitted for it without cutting the joints, there will daily distil into the receiver, without giving any fire below, a clear and sweet water, fresh and potable, and without any disagreeable or unwholesome quality. The quantity is but small that is obtained this way, but it is evident, that in the same manner a very immense quantity of the *sea* water is every hour made fresh, and raised up into the air from the infinite number of *plants* that grow in it. Dr. Lister even thinks that the tropic winds, which blow constantly one way, may be owing to this sort of cause. Philos. Trans. Nº 156. See the article TROPIC *winds*.

SEA *salt*. The chemists have, for many ages, been acquainted with many of the qualities, and much of the nature of this common substance, but not with the whole; they know what they can separate from it, and what they can afterwards procure, by admixtures with the residuum of the distillation, which is its basis; but they do not seem to have thought, of a long time, of enquiring into what that base was. They have always known how to separate an acid liquor from this *salt*, called the spirit of it, by breaking its union with the basis of the *salt*; and they know, that if a vitriolic acid be added to this basis, it makes what is called *Glauber's salt*, if a nitrous one, they procure what is called *quadrangular nitre*: but they never procured, and brought into view this basis of *sea salt* separate and pure, exempted from its acid, and in a state of being known as to what it is; they have found out that the basis of alum is a white calcarious earth, that the basis of green vitriol is iron, and that the basis of blue vitriol is copper; but they have been unacquainted with the basis of this most common of all *salts*. For want of this knowledge, no body has been able to recompose *sea salt*, or regenerate it after it has been decompounded by fire; and the judicious chemist never thinks he is master of a subject, till he can both destroy, and at pleasure reproduce it.

It has been generally agreed, that the basis of this *salt* is either an earth or an alkali; and it might be very possible to reconcile these opinions, by supposing it an alkaline earth, as there are many such, and so blending the two opinions in one. Mr. Du Hamel, however, has been at great pains on this subject, and has communicated to the Academy of Sciences, as the result of them, a very accurate and valuable account of this body.

A hasty observer may fancy to himself, that he has found out this basis at a very easy rate, by observing, that on the dissolving *sea salt* in oil of tartar by deliquium, there precipitates to the bottom a white earth. This was the first subject of Mr. Du Hamel's enquiries, but he found this could not be the real basis of the *salt*, nor indeed any thing essential to it, since it was in too small quantity to have sufficed for so great a purpose; and after the precipitation of it, there remained much fine and unaltered *salt*, on which the menstruum did not operate; and on all the trials he could make, he found it impossible to reproduce *sea salt* from the mixture of this earth with spirit of salt. It seems therefore most probable, that this earth was only accidentally mixed with the *salt*, at the time of its formation, but having no essential share in its composition. When an inflammable substance is mixed with nitre, its acid dissipates itself with a very little heat, and leaves its basis naked to the eye. Inflammable substances, mixed with vitriols, also greatly diminish the force of the union of their acid to their base, and consequently facilitate their separation; and on this principle Mr. Du Hamel had hopes that powder of charcoal, or filings of iron, might prove happy mediums for the separation of the acid of *sea salt* from its basis, but these had no effect. Chemists had observed that the *sea salt*, which enters the stomachs of animals with their food, was decomposed in their bodies; hence this gentleman tried animal and vegetable substances for this purpose, as also the inflammable minerals, but all these also without success.

When these trials had all proved fruitless, there appeared no way left, but that of the mixture of the vitriolic and nitrous acids, and the producing the Glauber's salt, and quadrangular nitre, for the subjects of after experiment. Having carefully made some Glauber's salt, the business was to drive off the acid from that mixt by fire; but no sort of distillation was found able to do this, as no fire is strong enough to disunite this acid from any mixture with an alkaline salt. It is well known, however, that the vitriolic acid easily unites itself to inflammable substances, and in that union constitutes common sulphur. The mixture of powder of charcoal with this Glauber's salt, produced readily a sulphur, but the acid, in running into this union, had carried the basis of the *sea salt* along with it, not left it behind as was expected; but the separation was afterwards effected, by pouring vinegar upon this sulphur; the consequence of which was, that the basis of the *sea salt* then remained charged only with the vegetable acid of the vinegar, much weaker than the mineral acid of vitriol, and therefore forming a combination much more easily broken, and from which the acid was to be raised into vapour, without any great difficulty, as it contained a large portion of an oily matter with it. This having then been wrought over by distillation, and the residuum strongly calcined, the basis of the *sea salt* was at length obtained pure.

A second operation of the same gentleman in this research, was the adding a nitrous acid to the residuum of the distillation of *sea salt* instead of a vitriolic one, and obtaining by that means a quadrangular nitre, instead of a Glauber's salt; and dissipating this spirit, by burning in a red hot crucible, with powder of charcoal, the basis of the *salt* was also prepared pure; and both this, and that by the former trial, appeared wholly the same substance.

The basis of *sea salt*, when thus found, appeared not to be an earth, as had been by many suspected, but a true salt itself, easily soluble in water, and proving itself to be an alkali by its effects with acids. It will not run into a liquor in the air, but moulders away into a fine powder, and is very cold upon the tongue, and has a bitterish taste. This salt appears much like the natrum, or nitre of the antients, or our common salt of the kali. The first of these is a native salt, found in the eastern countries, and which always has with it a large quantity of marine salt; and it is no wonder, when we know this to be what might have made

the basis of *sea salt*, that there should be found some places in the world where this basis may have concreted of itself, without any of that acid being near, which would have made it common salt, and that it therefore remained in the state of the base alone, and constituted this natrum. The other is also accounted for on the same principles, it being the salt produced by burning from a common *sea* plant, which must have imbibed a vast quantity of *sea salt*, and which may have been decomposed in its vessels, and left us only the base without the acid; which base cannot therefore but appear on the burning the plant, and evaporating water which had been poured upon its ashes.

This accurate account of Mr. Du Hamel's gives us a very perfect idea of what was, however, no new discovery in him, since Stahl had before affirmed this alkali to be the basis of *sea salt*, though he had wrapt up his meaning in so much obscurity, that it would never perhaps have been perfectly understood, without Mr. Du Hamel's assistance. Mem. de l'Acad. Par. 1736. See SALT.

SEA *sand*. This is one of the best improvements for many sorts of land, and if rightly understood by our farmers, might be of almost universal use; most of our shores are covered with it, where it is unregarded, and there are few places where it might not be had by water carriage. This *sand* is not of the nature of the common sand found in our pits, nor indeed properly to be called by that name, though it will be best understood by it among the people whose use it is recommended to. It is the fragments of *sea* shells beat to pieces against the shore, and ground almost to powder by the waves continually washing upon it. It is sometimes composed of shelly matter alone; but sometimes it is made up partly of this, and partly of broken stones: in this last case it is called *shelfy sand*, and is not much esteemed. See SAND.

In Cornwall they use this with great advantage, and have it of three colours. About Plymouth it is grey, or bluish, like ashes, which is owing to its being in great part made up of muscle and oister shells. Westward, near the Land's End, it is white; and in Scilly glistering, from a mixture of some spangles of talc among it. This last kind is made of the powder of scallop shells, and of the mouldering of a sort of moor stone, or white granite, not so hard as the common kind, and containing, like it, a large quantity of talc. On the northern side the *sand* is rich, and of a brownish or reddish colour, and is principally composed of the broken shells of cockles; and it owes that colour to the wash of the Severn, which falls foul and dirty with a yellowish mud into the Severn sea.

Beside these differences in the colour of the *sand*, there is also another difference, which is in the largeness or smallness of the grain. In many places the different parts of the same shore afford a larger and a smaller sort, and these are chosen according to the several occasions. The smallest sort gives its virtues out the soonest, but the large kind keeps the land in heart for the longest time together: the tenant therefore is always best pleased with the smaller, and the landlord with the larger. Philos. Trans. Nº 113.

SEA *sickness* is said to be prevented by drinking *sea* water mixed with wine.

SEA *swallow*, the name of a bird of the *larus*, or gull kind, called by authors *stema*, and common on our coasts. See the article STEMA.

SEA-*turtle-dove*, in zoology, the name by which we commonly call the little diver, called by Mr. Ray *columba Greenlandica*.

It very much resembles the coulterneb, or *anas arctica* of Clusius, only it is much smaller, and its legs are red, and it has no hinder toe. Its beak is long, not compressed, or flatted sideways, as in that bird, and a little crooked and sharp at the end. It has a large white spot on each side of the forepart of its head, and excepting that it is all over black. *Ray*'s Ornitholog. p. 245.

SEA *water*. See the article WATER.

SEAH, in Jewish antiquity, a measure of capacity containing six cabs. See CAB.

SEAMS (*Cycl.*)—SEAMS *of a ship*, are places where her planks meet and join together. There is also a kind of peculiar *seam* in the sowing of sails, which they call a *monk's seam*.

SEAMS *of a sail*, are of two sorts, *monk's seam*, and *round-seam*. See MONKS, *&c.*

Round SEAM, of a sail, is so called, because round like the common *seam*.

SEASIN, or SEASING, in a ship, the name of a rope by which the boat rides by the ship's side when in harbour, *&c.*

SEAT (*Cycl.*)—SEAT, in the manege, is the posture or situation of a horseman upon the saddle.

To *seat* a horse upon his haunches or hips, see the article PUT.

SEB, a word used by some chemists to express gold, and by others for alum.

SEBAR, or CEBAR, in the materia medica, a name by which the Arabians call the *lignum aloes*, or aloe wood, a perfumed aromatic drug.

SEBEL, an Arabian name for the disorder of the eye, usually called a *pannus*.

SEBESTENA, in botany, the name given by Dillenius to a genus of plants called *cordia* by Plumier, and under that name characterised by Linnæus. See CORDIA.

SECACUL, in the materia medica of the antients, a name given by Avicenna, Serapion, and others, to a root which was like ginger, and was brought from the East-Indies, and used as a provocative to venery.

The interpreters of their works have rendered this word *iringo*, and hence some have supposed that our eryngium, or eryngo, was the root meant by it; but this does not appear to be the case on a strict enquiry, and there is some reason to believe that the famous root, at this time called *ginseng*, was what they meant.

SECALE, *rye*, in the Linnæan system of botany, makes a distinct genus of plants, the characters of which are these. The cup is a case or cover, composed of two valves, and containing two flowers. The valves are strait, erect, and placed opposite to one another; and are sharp pointed, and smaller than the leaves of the flower. The flower is bivalve; the outer valve is rigid bellied, pointed, somewhat compressed with a rim upon its lower edge, and is terminated by a long awn or beard: the interior valve is flat, and pointed. The stamina are three capillary filaments, hanging out of the flower. The antheræ are oblong, and split at the ends. The germen of the pistil is of a turbinated form. The styles are two, reflex and hairy. The stigmata are single. The flower closely wraps up the seed, and when it is ripe opens, and lets it out. The seed is single, oblong, somewhat cylindric, naked, and pointed. *Linnæi* Gen. Plant. p. 17.

SECAMONE, in botany, a name by which the Ægyptians call a species of periploca common there, and distinguished by Mr. Tournefort by the name of *periploca foliis oblongis angustioribus*, the long narrow leaved periploca. See the article PERIPLOCA.

SECESPITA, among the Romans, a knife with a round ivory handle, adorned with gold and silver, which the flamins and priests used at sacrifices. *Pitisc.* in voc.

SECIUM, among the Romans, a term used to signify every thing the priests cut with the knife *secespita*, as the *libum*, *placenta*, &c. See LIBUM, *&c.*

SECLIA, a name by which some authors have called wormwood. See SANTONICUM *semen*.

SECTINEUS, a small, flat, and pretty long muscle, broad at the upper part, and narrow at the lower; situated obliquely between the os pubis, and the upper part of the os femoris.

It is commonly a single muscle, but is sometimes found double. It is fixed above by fleshy fibres to all the sharp ridge, or crista of the os pubis, and to a small part of the oblong notch, or depression on the foreside of the crista, in which the upper extremity of this muscle is lodged; from thence it runs down obliquely towards the little trochanter, under, and a little behind which, it is inserted obliquely by a flat tendon between the superior insertion of the vastus internus, and inferior insertion of the triceps secundus, with which it is united. *Winslow*'s Anatomy, p. 206.

SECOMIÆ, in natural history, the name of a genus of fossils, of the class of the *septariæ*, the characters of which are; that they are bodies of a dusky hue, divided by septa, or partitions of a sparry matter, into several more or less regular portions, of a moderately firm texture, not giving fire with steel, but fermenting with acid menstrua, and easily calcining.

The *septariæ* of this genus are, of all others, the most common, and are what have been known by the little expressive, or mistaken names of the *waxen vein*, or *ludus Helmontii*. The English name was acquired by the likeness of the body of the mass in some of the species, and of the septa in others, to yellow wax: and the Latin one was owing to this, that the famed Paracelsus, who had the cubic pyritæ in great esteem for dissolving the stone, called those bodies, from their resembling a die in shape, *ludus*; and Van Helmont afterwards mistaking the bodies of this genus for the *ludus* of Paracelsus, gave them in the same cases, and called them by the same name.

We have many species of these bodies common among us. Of the whitish or brownish kinds we have thirteen; of the yellowish five; and of the ferrugineous ones four.

Of the white or brownish kinds are, 1. A brown one, externally grey, with yellowish white septa. This is very common in Germany, and the chemists and apothecaries there, who use it as a remedy for the stone, always choose this species. We have it also common among us, and that in the neighbourhood of London; the clay-pits behind Gray's Inn Lane, and about Islington, affording it in great abundance. 2. A hard brown one with fewer septa, common in the same places with the former. 3. A hard blackish brown one with whitish partitions. This is a coarser, and much less beautiful kind than any of the former, and generally lies near the surface. It is common about Pancras, and in many other places. 4. A hard brownish yellow one, with yellowish white

white fepta. This alfo is common about London, and generally lies near the furface. 5. A hard greyifh brown one with brown fepta. This is a very firm and hard one, and is found in the clay pits about London, but generally lies deep. 6. A hard ferrugineous brown one with brown partitions. This is a particularly ftrong and firm kind, and is lefs common than the preceding kinds. It is found however in Surry, and on the coafts of Yorkfhire. 7. A foft whitifh one with brownifh yellow fepta. This is the moft foft, lax, and crumbly, of all the bodies of this genus, and is lefs common than moft of the kinds. It is found in Leicefterfhire and Yorkfhire, and has been met with at Paddington. 8. An elegant cruftated one with a bluifh nucleus, and brownifh yellow crufts. This is very rare, and has been found only about Loughborough, and once in the neighbourhood of Deptford. 9. A hard dufky brown one with very thick fepta. This is common in the cliffs, and on the fhores of Yorkfhire, and has been found alfo in the clay-pits about Richmond and Deptford. 10. A hard greyifh brown one, divided into talc by thick whitifh partitions. This is found in Leicefterfhire, Yorfhire, and Norfolk. 11. A brown compreffed kind with yellow fepta. This is often found of three feet in diameter. It is common in the cliffs, and on the fhores of Yorkfhire, Suffex, and Kent. 12. A whitifh grey very hard kind, looking like flint. This is a very fingular fpecies, and greatly fuperior to all the reft in the clofenefs of its texture. It is found near Peterborough in Northamptonfhire, and fometimes in the neighbourhood of London. And 13. a bluifh one, brown on the outfide, with white fepta. This is a very fingular, though not very beautiful fpecies, and is very fcarce. It is not known of any where, except at Loughborough in Leicefterfhire, and in the great clay-pit at Richmond. Thefe are the *fecomiæ* of thefe colours.

The yellow *fecomiæ* are, 1. A hard pale yellow one with few and thin partitions. This is found about Highgate, and is common on the fhores of Yorkfhire. 2. A foft dufky yellow one with very thick fepta. This has but little beauty, but it is very frequent in our clay pits, thofe about Deptford abounding with it. 3. A hard bright yellow one, with variegations of brown. This is a fingular and very beautiful fpecies, the brown variegations being fometimes found in veins, fometimes as a central nucleus. This is not known of any where, except on Mendip-hills. 4. A very hard brownifh yellow undulated one, with very few, and thofe whitifh partitions. This elegant fpecies is found alfo only on Mendip-hills. And 5. a hard greyifh yellow one, divided into talc by thin yellow partitions. This is a very beautiful mafs, and is frequently met with on the Yorkfhire fhores; fometimes alfo about Highgate.

The ferrugineous *fecomiæ* are thefe, 1. A round yellowifh ruft coloured one, with thin ftraw coloured partitions, found in Somerfetfhire, and about Iflington. 2. A roundifh ferrugineous red one with yellow fepta, very common in Northamptonfhire and Yorkfhire, and fometimes found in the clay-pits about Iflington. 3. A ferrugineous brown one with whitifh fepta; a fpecies of very little beauty, found on the fhores of Yorkfhire. And 4. a hard blackifh brown one, with a yellow cruftated coat, found about Richmond, and in fome other places. *Hill*'s Hift. of Foff. p. 510, feq.

SECOND (*Cycl.*)—SECOND, in mufic. What is faid in the Cyclopædia under this head wants correction; the truth is this. There are three kinds of *feconds* occurring in practice, the leffer, the greater, and the fuperfluous *fecond*; to which, if the enharmonic genus were reftored, we might add, the diminifhed *fecond*. The leffer *fecond* is the femi-tone major, and is nearly equal to $5\frac{1}{3}$ commas. The greater *fecond* is the tone, which being either major or minor, there muft alfo be two greater *feconds*; one nearly equal to $8\frac{1}{2}$ commas, and the other to $9\frac{2}{3}$ commas: but practitioners ufually confound thefe two. The fuperfluous *fecond* is a tone major, and femi-tone minor [a]; the other fuperfluous *fecond*, arifing from the tone minor and femi-tone minor, is not in ufe. Laftly, the diminifhed *fecond* is a femi-tone minor lefs than the leffer *fecond*; that is, equal to the diefis enharmonica. Thus between E and F ♭, or between A and B ♭ ♭, would be a diminifhed *fecond*, as alfo between G fharp and A ♭. This laft has been practifed by an eminent mufician of this age [b]. —[[a] See the Table, under INTERVAL. [b] Mr. Handel, in the Oratorio of Samfon, in the fecond part of the fong, *Return, return, O God of hofts.*]

Some authors, as Ozanam [c], call the femi-tone minor by the name of *diminifhed fecond*; but this is contrary to the analogy in like cafes, where diminifhed is ufually applied to intervals a femi-tone minor lefs than a true diatonic interval. Thus the diminifhed feventh is a femi-tone minor lefs than the flat feventh, or feventh minor.—[[c] Dict. Mathemat. p. 653.] See the Table, under INTERVAL.

Diminifhed SECOND, in mufic. See DIMINISHED *fecond*.

SECOND *de l'oreille*, in anatomy, a name given by Vieuffens and others to a mufcle of the ear, called by Cowper and others *ftapidaceus*, and *ftapedis mufculus*; and by Albinus *ftapedium*. Winflow calls it *le mufcle de l'etrier*. See EAR.

SECOND *deliverance*, *fecunda deliberatione*, a judicial writ that lies after nonfuit of the plaintiff in replevin, and a returno habendo of the cattle replevied, adjudged to him that diftrained them; commanding the fheriff to replevy the fame cattle again, upon fecurity given by the plaintiff in the replevin for a redelivery of them, if the diftrefs be juftified. It is a *fecond* writ of replevin, &c. F. N. B. 68. Terms of Law. *Blount*, *Cowel.*

SECRETARIUM, among the Romans, a reclufe room, where the judges confidered the caufes that had been litigated before them, and came to a refolution what fentence they were to pronounce from the tribunal. It was moft ufually feparated from the tribunal by a veil. *Pitifc.* in voc.

SECTA (*Cycl.*)—SECTA *ad curiam*, a writ which lieth againft him who refufeth to perform his fuit to the county court, or court baron. F. N. B. 158. *Blount*, *Cowel.*

SECTA *curiæ*, in our old writers, fuits and fervice done by the tenants at the court of their lord. *Paroch.* Antiq. 320.

SECTA *facienda per illam quæ habet æniciam partem*, a writ to compel the heir that hath the elder's part among coheirs, to perform fervice for all the coparceners. Reg. orig. 177. *Cowel.*

SECTA *faldæ*. See FALDEGE, *Cycl.* Not.

SECTA *molendini*, a writ lying where a man by ufage, time out of mind, &c. has ground his corn at the mill of a certain perfon, and afterwards goes to another mill with his corn, thereby withdrawing his fuit to the former. And this writ lies efpecially for the lord againft his tenants, who hold of him to do fuit at his mill. Reg. orig. 153. F. N. B. 122. *Blount*, *Cowel.*

SECTA *regalis*, a fuit by which all perfons were bound twice in a year to attend the fheriff's tourn, and was called *regalis*, becaufe the fheriff's tourn was the king's leet; wherein the people were to be obliged by oath to bear true allegiance to the king, &c. *Blount.*

SECTA *unica tantum facienda pro pluribus hæreditatibus*, a writ that lies for an heir who is diftrained by the lord to do more fuits than one, in refpect of the land of divers heirs defcended to him. Reg. orig. *Blount*, *Cowel.*

SECTILIA, among the Romans, pavements laid with ftones cut into various forms. Suetonius diftinguifhes them from thofe that were teffelated. *Pitifc.* in voc.

SECTION (*Cycl.*)—*Cæfarian* SECTION. Many have exclaimed againft the cruelty of this operation, and certainly it is too terrible to be ufed on any, but the moft emergent occafions; but there feem three cafes in which it is juftifiable, nay abfolutely neceffary. The firft is when the mother is dead, either in labour, or by fome other accident, and the child is perceived to be alive. The fecond is when the mother is living, and the fœtus dead, and incapable of being extracted by the common paffages by any help of the midwife. And the laft, when the mother and child are both living, and there is found an utter impoffibility of delivery any other way. In all thefe cafes the Cæfarian practice is juftifiable to fave life, that muft otherwife be inevitably loft.

In the firft cafe, the operation muft be performed immediately after the death of the mother, otherwife it is to no purpofe, for the child can live but a very little time afterwards in the body. The furgeon is, in this cafe, to make a crucial incifion, as in the common diffections; or a longitudinal one on one fide, without regard to the courfe of the fibres or veffels; and if the fœtus fhould have fallen into the cavity of the abdomen, through a rupture of the uterus, it fhould then be taken out; or if it he yet in the womb, or in the fallopian tube, thefe parts muft be carefully opened, and the child heing taken out, muft have Hungary water, or the like, held at fome fmall diftance from its nofe to revive it, and the navel ftring be tied up as ufual. The fœtus is not always preferved, or found alive after this operation; but as there is often a probability of it, it is certainly better to open an hundred dead women in vain, than to lofe the life of one infant.

In the fecond cafe, when a dead fœtus is contained in the cavity of the abdomen, in the fallopian tube, or in a kind of hernia or facculus without the abdomen, of all which cafes there are inftances recorded; or when from the particular ftructure of the parts, as is fometimes the cafe in crooked women, and others; and when, as in many inftances, there is no poffibility of the extraction of the infant, even by incifion of it, there is no way but the opening the abdomen, and, if neceffary, the uterus of the mother, and taking out the fœtus; and this is often the means of preferving the mother, and when in parallel cafes the child is alfo alive, there have been not a few inftances of both being preferved. *Heifter*'s Surgery, p. 29.

The Cæfarian *fection* is recommended by feveral authors, and Mr. Helvetius communicated to the Academy of Sciences at Paris, a well attefted hiftory of a woman recovering after the operation had been performed upon her by a midwife. Vid. Hift. de l'Acad. des Scienc. 1731.

We have alfo an account of this operation fuccefsfully performed by a midwife in Ireland. See Med. Eff. Edinb. Vol. 5. art. 37.

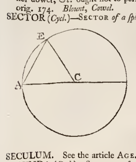
There

There is likewise an account of the Cæsarian operation successfully performed by a butcher on a woman in Ireland. Vid. Phil. Transf. N° 461. sect. 17.

Cyprianus, professor at Franeker, gives an extraordinary case of the Cæsarian operation, whereby a fœtus, which had been dead twenty one months, was drawn out of the tuba uteri, yet the mother preserved [d]. M. Jobert, physician at Chateau Thierri, relates the history of a woman in the neighbourhood of that place, who was twice delivered of children by the Cæsarian operation; the first time in 1682, the second time eleven months after, and recovered from both [e]. —[[d] Act. Erud. Lips. An. 1711. p. 82, seq. [e] Jour. des Scav. Tom. 21. p. 374.]

SECTIS *non faciendis*, a writ brought by a woman, who for her dower, *&c.* ought not to perform suit of court. Reg. orig. 174. *Blount, Cowel.*

SECTOR (*Cycl.*)—SECTOR *of a sphere.* The *sector of a sphere*, generated by the revolution of the *sector* of a circle C A E about the radius A C, is equal to a cone, whose base is equal to the portion of the spherical surface generated by the arch A E, or to the circle described with the radius A E, and whose height is equal to C A, the radius of the sphere. Arch. de Sphær. et Cyl. *Mac Laurin*'s Fluxions, Introd. p. 15.



SECULUM. See the article AGE.

SECUNDA (*Cycl.*)—SECUNDA *super oneratione pasturæ*, a writ which lieth where admeasurement of pasture hath been made; and he that first surcharged the common doth it a second time, notwithstanding the admeasurement. Old Nat. Br. 73. *Blount, Cowel.*

SECUNDANS, in mathematics, an infinite series of numbers, beginning from nothing, and proceeding as the squares of numbers in arithmetical progression, as 0, 1, 4, 9, 16, 25, 36, 49, 64, *&c.*

SECUNDINES (*Cycl.*)—It very often happens that these are retained in the womb after childbirth, and great mischiefs ensue from it. The assistance of a skilful hand is, in many cases, necessary to the getting them out; and this is to be done with great care and speed, before the uterus closes itself upon them, otherwise they occasion terrible hæmorrhages, faintings, and often inflammatory and putrid fevers.

The patient herself may greatly promote the expulsion of these, by any forcible emotion of the body, as by a forced cough, or by sneezing; the midwife at the same time is gently to pull them by the navel string, but this must be done very cautiously, for fear of its breaking. If this fails, the cautious introducing the hand often sets all right, or the use of gently pellent medicines may be called in; and to these may be added broths, with saffron in them, and by the use of common clysters great good is often done: but, if after all this care, there yet remain some fragments of them behind, there usually arises a fever within twelve hours; and in this case the utmost care must be taken to prevent putrefaction, and expel the remains of them. To these purposes medicines prepared with myrrh, amber, saffron, and the cortex eleutherii, are of the greatest service; and to these may be added occasionally the colliquating and attemperating salts, such as tartarum vitriolatum, and nitre. *Junker*'s Consp. Med. p. 723.

Notwithstanding the great danger that usually attends the leaving any part of this behind, at the time of delivery, there are instances of some persons lucky enough to escape; the substance left behind remaining uncorrupted, till the time of its being afterwards discharged.

Kerkring gives us an instance of this which fell under his own knowledge. A woman had a large portion of it left behind, where it remained four months, and at the end of that time was discharged uncorrupted, and without any hurt to the person. *Kerkring*'s Spicileg. Anat.

SECUNDUS (*Cycl.*)—SECUNDUS *mallei*, in anatomy, a name given by Duverney, and some others, to one of the muscles of the ear. It is the *internus auris* of Cowper and others, and is most properly named by Albinus *tensor tympani*.

SECUNDUS *oculum movens*, in anatomy, a name given by Vesalius to that muscle of the eye, called by Riolanus and others *superbus*, and *elevator oculi*, and by Albinus the *subductor*, one of his four musculi recti of the eye.

SECURIDACA, in botany, the name of a genus of plants, the characters of which are these. The flower is of the papilionaceous kind, and its pistil, which arises from the cup, finally becomes a strait, flatted, annulated, and jointed pod, which contains in every joint one seed, of a rhomboidal form, and marginated on its inner side.

There is only one known species of this genus, which is the yellow *securidaca*. *Tourn.* Inst. p. 699.

SECURITATEM *inveniendi quod se non divercat ad partes exteras sine licentia regis*, an antient writ lying for the king against any of his subjects, to stay them from going out of this kingdom into foreign parts; the ground whereof is, that every man is bound to serve and defend the commonwealth, as the king shall think fit. F. N. B. 85. *Blount, Cowel.*

SECUTOR, among the Romans, most commonly signified an attendant upon great men. *Pitisc.* in voc.

Secutor, in a more limited sense, denoted the gladiator who engaged with the *retiarius*. *Pitisc.* Lex. Ant. in voc. See the article RETIARIUS.

SEDAB, in botany, a name given by the Arabian physicians to the wild, or mountain rue, a plant common in Syria, Greece, and other places. Avisenna supposes the gum, which he calls *gentum*, or *jentum*, to be produced from this plant, but very erroneously, that gum being obtained from the roots of the thapsia, or deadly carrot.

SEDATIVUM *sal.* This *salt* may be obtained by crystallization in the following manner. Take four ounces of borax, and one ounce one drachm of the most concentrated oil of vitriol; put the borax into a glass retort, pour on it half an ounce of common water after the oil of vitriol, and expose the mixture to a fire gradually encreased: after the phlegm has passed off, and even while it is passing, there arise flowers, or a volatile salt, in beautiful foliated laminæ, some of which always melt by the heat of the fire; after the operation is over, the finest of the flowers are to be carefully gathered: these are what stick to the neck of the retort. Those that are grey, are to be thrown upon the remaining mass; this mass is to be dissolved in water, filtrated, and evaporated gradually; sometimes, even without evaporation, the shining talcous laminæ are to be seen in the liquor: after twenty four hours standing the water is to be poured off from these laminæ, they are to be washed with fresh water, and then dried carefully in a warm place. If these crystals do not calcine in the place where they are put to dry, nor in the sun's heat, it is a sign there is nothing crystallized but the sal neutrum; if they do calcine, it is a proof that there is some Glauber's salt formed of the borax and the vitriolic, and crystallized in the mass. This method of procuring the *sal sedativum* by crystallization, was an invention of Mr. Geoffroy; every body had before thought it could only be obtained by sublimation. Philos. Transf. N° 436. p. 40. See SAL.

SEDEM *attollens*, in anatomy, a name given by Vesalius and others to the muscle, now more generally known by the name of *levator ani*.

SEDENTARIUM *os*, a name given by some anatomical writers to the protuberance of the os coxendicis, on which the whole weight of the body rests in sitting.

SEDINA, in the materia medica, a word used by some writers to express dragon's blood.

SEDITION, among civilians, is used for an irregular commotion of the people, or an assembly of a number of citizens without lawful authority, tending to disturb the peace and order of the society.

This offence is of different kinds: some *seditions* more immediately threatening the supreme power, and the subversion of the present constitution of the state; others tending only towards the redress of private grievances. Among the Romans, therefore, it was variously punished, as according as its end and tendency threatened greater mischief. See l. 1. cod. *de Seditiosis*, and Math. *de Crimin.* l. 2. n. 5. *de læsa majestate.* In the punishment, the authors and ringleaders were justly distinguished from those, who with less wicked intention joined, and made part of the multitude.

The same distinction holds in the law of England, and in that of Scotland. Some kinds of *sedition* in England amount to high-treason, and come within the Stat. 25 Edw. III. as levying war against the king. And several *seditions* are mentioned in the Scotch Acts of Parliament as treasonable. *Bayne*'s Crim. Law of Scotland, p. 33, 34.

The law of Scotland makes riotous and tumultuous assemblies a species of *sedition*. But the law there, as well as in England, is now chiefly regulated by the Riot Act, made 1 Geo. I. only it is to be observed, that the proper officers in Scotland, to make the proclamation thereby enacted, are sheriffs, stewards, and bailies of regalities, or their deputies; magistrates of royal burroughs, and all other inferior judges and magistrates; high and petty constables, or other officers of the peace in any county, stewartry, city or town. And in that part of the island, the punishment of the offence is death and confiscation of moveables: in England it is felony. See RIOT, *Cycl.*

SEDMA, a word used by some as a name for the *lapis hæmatites.*

SEDUM, *houseleek*, in botany, the name of a large genus of plants, the characters of which are these. The flower is of the rosaceous kind, consisting of several petals, arranged in a circular form. The pistil, which arises from the cup, finally becomes a fruit, composed of several cases or sheaths, constipated together into a sort of head, and containing a number of small seeds.

The species of *houseleek*, enumerated by Mr. Tournefort, are these. 1. The great tree *houseleek*. 2. The common great *houseleek*. 3. The narrower leaved great *houseleek*. 4. The largest

largest common *sedum*. 5. The broad leaved *sedum* with large white flowers. 6. The large mountain-*sedum* with dentated leaves. 7. The large mountain-*sedum* with whole leaves. 8. The woolly mountain-*houseleek*. 9. The smaller woolly mountain-*sedum*. 10. The large Alpine rose-*sedum* with sharp pointed leaves. 11. The middle sized Alpine rose-*sedum* with red prickles. 12. The greenish hairy Alpine rose-*sedum*. 13. The long leaved hairy Alpine *sedum*. 14. The hairy Alpine *sedum* with the disk of the flower green, and the corona purple. 15. The smaller white flowered cylindric leaved *sedum*. 16. The larger cylindric leaved white flowered *sedum*. 17. The small cylindric leaved *sedum*, called the *lesser houseleek* of the shops. 18. The smaller cylindric leaved yellow flowered *sedum*. 19. The small round leaved *sedum*. 20. The sharp pointed leaved small yellow *sedum*. 21. The lesser *sedum* with broad and thick stalks. 22. The lesser yellow *sedum* with inflated stalks. 23. The deep yellow flowered long leaved *sedum*. 24. The red flowered field-*sedum*. 25. The little yellow flowered sharp tasted *sedum*. 26. The smallest yellow flowered *sedum*, insipid to the taste. 27. The little insipid white flowered *sedum*. 28. The pale flowered Alpine *sedum*. 29. The Alpine *sedum* with large red flowers. 30. The hairy purple marsh-*sedum*. 31. The white flowered echinated, or stellated *sedum*. 32. The yellow flowered echinated *sedum*. 33. The *sedum*, commonly called *cepæa*. 34. The purple flowered *cepæa*. 35. The smallest mountain-*sedum* with little purple flowers, and stellated seeds. 36. The coris-leaved Alpine *sedum*. 37. The shrubby heath-like African *sedum*. These are the genuine species of *sedum*; but beside these, authors have called many other plants by this name, most of them properly of the saxifrage kind. *Tourn.* Inst. p. 262.

The great *houseleek* was called by many names among the Greeks, as *zoophthalmus*, and *buphthalmus*; the latter of these confound it with one of the corymbiferous plants, and it is not to be known which of two so different vegetables the authors mean, without examining the virtues they ascribe to it.

There is however another name, by which it is called, which yet more perplexes the sense; this is *ambrosia*, a word by which we express the botrys, or oak of Jerusalem, a small garden plant, but by which they expressed the lilly, the *houseleek*, and several other plants.

SEED (*Cycl.*)—The exterior form, and even the internal structure, of the generality of vegetable *seeds*, have been supposed by some so much alike in the several kinds, and of so little curiosity and beauty in the whole, that they have been little regarded by the curious; but when nearly examined with the help of microscopes, they are found to be worthy of a greater attention: those which appear most like to one another, when viewed by the naked eye, often proving as different, when thus examined, in their several forms and characters, as the different genera of any other bodies of the creation. If their external forms carry all this variety and beauty about them, their internal structure, when laid open by different sections, appears yet more admirable.

The *seed* of the musk scabious is amazing in its shape and structure: it resembles in figure an octagonal vase, with a scalloped brim; the whole is bell-fashioned, having ribs or divisions, which run down from the mouth of the vase, and thence becoming narrower, form the bottom. Between these ribs, down to the beginning of the narrow part, it is clear, though not wholly transparent, and from thence to the bottom the ribs are hairy. This vase contains a *seed*, which is like a pestle standing in a mortar. The pestle stands loose in an octagonal case, but the narrowness of the mouth of this vase hinders the pestle's being drawn out, because its extremity within is rounded, and thicker than any other part of it. From its upper end there arise five spiculated aristæ, or awns, whose little thorns are directed upwards, and are thereby prepared to cause the *seed* to recede from any thing that might injure it on being touched. The bason, from which these aristæ rise, is of a fine green colour, and they are of an elegant shining brown.

The *seed* of the angelica is one of the most fragrant in the smell in the world. When the outer husk of this *seed* is pulled off, the nucleus appears of a brownish colour, and of an elliptical shape. By the help of the microscope we soon discover what it is that produces this charming smell; this is a fine amber coloured gum, which appears laid in ridges, dispersed alternately with others of a brownish colour, longitudinally, all over the *seed*, and on the flat side there is a white part, which is a sort of theca, which receives a very minute stylus from the pedicle that supports it.

The medicinal *seed*, commonly known in the shops under the name of *grain of paradise*, is one that promises very little from its external appearance, being only a brown *seed* of an irregular surface, with many flats and angles, and having an apex like the mouth of a purse when drawn together with a string; from this unpromising aspect, however, there arises a very wonderful appearance on dissection. In a longitudinal section we see first the edge of the brown cortex, next within that appears a black pithy substance, and within that a very white matter, lodged in a radiated form: this resembles a fine white salt, and is probably a mixture of a volatile salt, and a farinaceous matter. Its radiated disposition, and extremely pungent taste, favour also this opinion. But there is in this *seed* a yet far more curious particular than these; the center of every *seed* is occupied by a small piece of perfect camphor: this is, in all respects, the same with the common camphor sold in the shops, and is always of the figure of a vinegar cruet, having a round large bottom, and a long and narrow neck. This is invariably the appearance in every *seed*, and that not only in this, but in other *seeds* of the same kind.

The *seed* of the great maple, which we commonly, but improperly call the *sycamore-tree*, consists of a pod and its wing: two of these grow upon a pedicle with the pods together, which makes them resemble the body of an insect with its expanded wings. The wings are finely vasculated, and the pods are winged with a fine white down, resembling silk: this contains a round compact pellet, covered with a brown membrane, that sticks very closely to it. When this is pulled off, instead of discerning a kernel, as in other *seeds*, there appears an entire green plant, folded up in a most surprising manner. The pedicle of this is about two eighths of an inch long, and its seminal leaves of about six eighths each: between these the germina of the next pair of leaves are plainly visible to the naked eye, but with a microscope they are seen with the greatest beauty and perfection. See Tab. of Microscopical Objects, Class 2.

These, and a number of such other beauties in this part of the creation, are described at large by Dr. Parsons in his work, entitled *A Microscopic Theatre of Seeds*, to which we refer for the rest. Philos. Trans. N° 474. p. 187.

The increase of the *seeds* of plants is surprising. The upright mallow, for instance, has been computed to produce 200000 *seeds* from one. See Philos. Trans. N° 468. sect. 4.

Most kinds of *seeds* should be prepared for a microscopical examination, by steeping them in warm water till their coats are separated, and their seminal leaves may be opened without laceration. But *seeds*, while dry, and without any preparation, are of an almost infinite variety of shape, and afford a number of pleasing objects for the microscope.

The *seeds* of strawberries rise out of the pulp of the fruit, and appear themselves like strawberries. The *seeds* of the several sorts of poppies resemble kidneys in shape, but have a number of furrows and ridges on their surfaces, very curiously disposed with regular sides and angles. From these *seeds* there may also be commonly shaken a dust, which looks very pretty before the microscope, having nearly the same appearance with the surface of the *seeds*, but having the advantage of being transparent. This dust is composed of the fine membranes which have lain between the *seeds*, and which by the pressure of the *seeds* against them have received the very marks of every part of the *seeds*.

The *seeds* of the lesser moonwort, of tobacco, chervil, lettuce, thyme, parsley, and a multitude of others, afford also a very pleasing entertainment. The antients imagined, that the ferns and capillary plants produced no *seeds*, and their mistake could never have been rectified by the naked eye; but the microscope has discovered, that all the several sorts of fern, harts-tongue, maiden-hair, and the like, are so far from being barren in this respect, that they are really amazingly fruitful. The *seed* vessels of these plants are placed on the back part of their leaves, and the dust which flies off from them in such great quantities, when we handle them, is no other than their *seeds*. The *seed* vessels appear to the naked eye like brown or black scurff, on the backside of the leaf, but when viewed by the microscope, they resemble little circular tubes, divided into several cells, and containing a multitude of *seeds*. When the *seeds* are ripe, the vessels fly open with a spring, and throw them out every way in form of dust. *Baker*'s Microscope, p. 250.

Mr. Lewenhoek observes, that the meally substance in the *seeds* of beans, pease, wheat, barley, and other kinds of grain, and the generality of other large *seeds*, is always enclosed in certain small membranes, representing so many little bags or sacks. On observing these membranes more nicely, they were found to be all full of small holes, through which he could see the light, and which he judged to be no other than the remains of truncated vessels, which had been torn off in separating the part, and which serve to compose a great part of the membranes; and it is probable, that each minute particle of the farina of these *seeds* is nourished by the vessels, of which we, in this view, see the truncated ends. These vessels are more easily seen in beans and pease, than in the grains of wheat, *&c.* whose membranes are so extremely thin and brittle, that they are destroyed with the least touch. In wheat, however, there is this singularity, that one globule of the farina being broken, is always seen to be composed of many more, or that many much smaller globules were contained in every one of these larger ones. The membranes in barley, in which the small globules of farinaceous matter are contained, are much thicker and stronger than in wheat, but much less strong than in the leguminous *seeds*. See Tab. of Microscopical Objects, Class 2.

There is great reason to believe, that in all *feeds*, which contain a large quantity of farinaceous matter, the cafe is the fame as in thefe, and that they all confift internally of fmall globules, collected into larger ones, and enclofed in membranes; which, on a ftrict examination, appear to be little other than congeries of veffels deftined to fend nourifhment to the feveral inclofed globules.

The oil in almonds, and other fuch *feeds*, is in the fame manner contained in a fort of fmall veffels, which are very numerous, and diftinctly vifible. When a fmall piece of the pulp is examined with a good microfcope, all thefe fmall veffels, and the membranes they make a part of, proceed from the fkin or inner covering of the *feed*, in which they are found; and as the meally fubftance receives its encreafe from the veffels which are in the cells; and as the plant is formed between the cells, during the time that the *feed* lies in the earth; and as the little orifices in the fkins of animals, and of fruits, are fo formed, as to difcharge the fuperfluity of their moifture, and are fhut in fuch a manner, that no moifture from the common air can be received into them: fo, on the contrary, the orifices of *feeds* are fo formed, that they will admit moifture to pafs inwards, and accordingly moifture is driven into them as they lie in the earth. The *feed* upon this muft neceffarily fwell, after this a fermentation arifes, it requires then a greater fpace, and according to the particular ftate of the fibres, and the particles which lie in the cells, and which have derived their nourifhment from the cells, the meally fubftance is by degrees driven out of them into the fubftance of the young plant; which by this means encreafes fo much in bulk, that the root is become able to furnifh it with nourifhment from the earth. The office of the internal part of the *feed* is then over, and we fee accordingly, that it is by that time almoft wholly wafted. Phil. Tranf. Nº 368. p. 203. See Tab. of Microfcopical Objects, Clafs 2.

Many experiments have been made, in order to prove that the *feeds* of all plants derive their conftituent matter from the woody central parts of the plant. Thus apple trees, when they grow hollow, will bear good fruit, but with empty and imperfect *feeds*. Barberry trees, when the roots are bored through, are faid to bear fruit abfolutely without *feeds*; and the gardiners fay, that if the woody part of the roots of parfley be cut out, the plant will continue to thrive in all appearance, but that it will never afterwards produce *feeds* that will propagate the fpecies. It is to be acknowledged that hollow oaks and elms produce *feed* that is as good as that growing on the foundeft trees of the fame fpecies; but the elm is all timber to the bark, and an oak, when it is putrid to the heart, may ftill have firm wood enough to convey a proper nourifhment from the root to the acorn. The roots may be found, when the body of the tree is very much decayed by water let in at the top of the pollard tree, or at the loppings of the branches; and we fee that beans, wheat, and other grain, grow well, if the eyes and parts next adjoining be whole, though the beans be full of great holes in other parts, or the main body of the wheat be cut off with fciffars.

The people who recommend boring of the barberry roots, to have fruit without ftones, order therefore that the borings be very compleat in the roots for that purpofe. It is obferved, in countenance of this doctrine, that fome trees are lefs fruitful, or even altogether barren, by the exceffive growth and hardnefs of the timber, and thefe are cured by crofs hackings or cuts, done with fharp inftruments through the bark, and into the wood: they alfo do the like injuries to the roots on the fame occafion, and often fplit them lengthwife, putting a ftone into the flit, that they may not grow together again. When this remedy is applied both to the ftem and roots, it feldom fails of fuccefs, but when only to one, it fometimes miffes.

As the heart of the wood, or its more folid fubftance, are fuppofed thus to furnifh the matter of the *feeds*, the bark is fuppofed to furnifh the matter of the pulp of the fruit. The experiment has been made, by debafing and vitiating its juice, and the fruits have accordingly been debafed. Thus if refts be made for water on the body of a Kentifh codling tree, and water poured frequently into thefe cavities, fo as always to keep up a fupply for the bark, the apples will grow to an immoderate fize, and be infipid; part of their pulp will be fo relaxed, as to look like the pulp of a lemon, and on hanging but a moderate time on the tree, they will be as rotten, as if laid on heaps when fully ripe. Philof. Tranf. Nº 46.

Change of SEED, a term ufed by the farmers to exprefs the common, and, as they fuppofe, neceffary cuftom, of changing among one another the *feed* of their lands, as wheat, and the like, it being a received opinion, that the *feed* produced on one land will grow better on another, than on that which produced it, though the fame fpecies of plant be fown.

Seeds, in their natural climate, do not degenerate, unlefs culture has improved them; they then indeed are liable, upon omiffion of that culture, to return to their natural ftate again. Whatever benefit arifes to the farmer from the changing the *feed* of the fame fpecies, is from caufes which are themfelves the effects of different climates, fuch as heat and moifture, which may vary very much in the fame neighbourhood. There is a mountain in the Mogul's country, which on the fouth fide produces Indian plants, and on the north fide European ones, from different expofures. Some land retaining water longer is colder, and fome letting it pafs off quicker is warmer; as it may alfo be from the nature and figure of its parts, which retain more of the fun's heat than others. Sandy and gravelly grounds are always warmer than others, if they have fome hollow and fpungy ftratum underneath, that will let the water pafs off.

The benefit arifing from the change of *feed* is owing to thefe changes, not to the change of food, and thefe caufes fhew their effects chiefly in the generation of the *feed*. Flax *feed*, brought from Holland, and fown here, will produce as fine flax as it does there, but in the next generation it will degenerate, and become coarfer; by this means it will continue to degenerate every year, till after two or three years it is no better than our own *feed* produces, and yet the land fhall be as good for this coarfe fort, as when it produced the fine; fo alfo it is, when the *feeds* of our own wheat are changed between farmer and farmer. And thus filk worms hatched and bred in France, of eggs brought from Italy, will make as fine filk as the Italian; but the eggs of thofe laid in France, will produce worms that make no better filk than thofe produced in France, though their food is all the while the fame.

Common barley, once fown in the burning fands in Wiltfhire, will for many years after, if fown on indifferent warm ground, be ripe fooner than any other barley by two or three weeks; but if fown on cold grounds farther north, it will be as late as any other barley, after two or three years. The weeds, which perplex the farmers in every field, grow as ftrong and troublefome one year as another, and that without any change of *feed* at all. Thefe feem therefore to have been the natural produce of our foil, and corn and other ufeful plants to have been brought from other places, and improved by culture; thefe will therefore no longer retain their perfection and value, than fuch culture is continued to them.

Laurembergius has carried this notion of degeneracy and change from the foil, fo far as to affirm that wheat will, in fome places, degenerate into rye; and in other places, rye will be exalted into wheat by the foil: but thofe who are acquainted with botany know, that a horfe might as foon be changed into a bull by feeding in an improper pafture, as one plant degenerate into another by fault of the foil. *Tull's* Hufbandry, p. 116.

SEEDY, in the brandy trade, a term ufed by the dealers to exprefs a fault that is found in feveral parcels of French brandy, and which renders them unfaleable. The French fuppofe that thefe brandies obtain the flavour, which they exprefs by this name from the weeds which grew among the vines, from whence the wine, of which this brandy was made, was preffed.

However it be, the thing is evident, and the tafte not of any one kind; but fome pieces of brandy fhall tafte ftrongly of annifeed, fome of caraway feed, and fome of other of the ftrong flavoured feeds of plants, principally of the umbelliferous kind; fo that it fhall be rather taken for annifeed, caraway, or fome other water, than for brandy.

The proprietor of fuch brandies is always at great trouble to get them off, and ufually is reduced to the neceffity of mixing them in fmall quantities with pieces of other brandies, fo as to drown and conceal the tafte; and where he has not opportunities of doing this, is obliged to fell them on very difadvantageous terms.

The bufinefs of rectification of fpirits is very little underftood abroad, though very much practifed with us; and a man in France or Holland, who could take off this tafte from thefe brandies, might get great advantages by it. There is no doubt but that the fame means, which we ufe to rectify malt fpirits, that is to clear it of its naufeous and ftinking oil, which always rifes with it in the firft diftillation, would alfo ferve to purify thefe brandies, and by leaving thefe extraneous oils behind, render them as well tafted as any others; fince there is no queftion, but that the oil of malt, which is a principle of the fame ingredient with the fpirit, is more firmly united to it than thefe flavouring oils in the brandy, which are not the produce of the grape, but of fome foreign matter only accidentally mixed with it. See the article RECTIFICATION.

It is a miftake to imagine, that all the brandies made in France are fo fine as thofe which we meet with on the keys of London; on the contrary, there are many hundred pieces made every year, which are as badly flavoured as our coarfeft malt fpirit. But the cafe is this, they fend the beft brandies, and the beft wines to England, where they can get the beft prices for them. In Holland, on the contrary, the mart of goods of all forts, it is fometimes difficult to pick one piece of good brandy out of fifty, the general run of them being either *feedy*, or mufty, oily, or otherwife infected with fome unnatural and difagreeable flavour; and thefe

these are the sorts which in France they despair of curing by re-distillation, or bringing to the state of three fifths, or *trois cinques*, as they express their stronger brandies. *Shaw's* Essay on Distillery. See TROIS *cinques*.

SEELING (*Cycl.*)—SEELING, at sea, is used in the same sense nearly with heeling. When a ship lies down constantly, or steadily on one side, the seamen say she *heels*; and they call it *seeling*, when she tumbles on one side violently, and suddenly, by reason of the sea forsaking her, as they call it; *i. e.* the waves leaving her for a time in a bowling sea. When a ship thus tumbles to leeward, they call it *lee-seel*; and in this there is not much danger, even in a storm, because the sea will presently right her up again; but if she rowls or *seels* to windward, there is fear of her coming over too short or suddenly, and so by having the sea break right into her, be either foundered, or else have some of her upper works carried away.

SEGITH, a word used by some of the chemical writers as a name for vitriol.

SEGMENTUM, among the Romans, an ornament of lace used by the women on their shoulders, which, according to some, resembled our shoulder knots. *Pitisc.* in voc.

Segmenta were likewise a kind of tessellated, or Mosaic pavements, made up of pieces of various shapes and colours, but which had an uniform and regular arrangement. *Pitisc.* Lex. Ant. in voc.

SEGUE, in the Italian music, is often found before *aria*, *alleluja*, *amen*, &c. to shew that those portions or parts are to be sung immediately after the last note of that part over which it is writ. But if these words, *se piace*, or *ad libitum*, are joined therewith, it signifies that these portions may be sung, or not, at pleasure.

SEGUENZA, in the Italian music, a kind of hymn sung in the Roman church, generally in prose. The *seguenze* are often sung after the gradual, immediately before the gospel, and sometimes in the vespers before the magnificat. They were formerly more used than at present.

The Romish church has retained three *seguenze*, called *le tre seguenze dell' anno*. They are *lauda Sion salvatorem*, &c. *victimæ paschali laudes*, &c. *veni sancte Spiritus*, &c. These are sung to music in many places. There is also one called *dies iræ*, *dies illa*, in the funeral service, which is admirably well set, and on which Legrenzi, Lully, and others, have made excellent compositions. *Brossard.*

SEIGNETTE's *salt*, a name given in France to a kind of sal polycrestus, famous a long time in that kingdom as a purge. It was otherwise called *sal rupellensis*, and was invented by Mr. Seignette. The Paris Academy took it into consideration, and Mr. Geoffroy discovered that it was only a kind of soluble tartar, formed of cream of tartar and common pot-ashes. See RUPELLENSIS *sal*.

SEIGNIORY, *dominium*, in our law, is used for a manor or lordship. *Blount*, *Cowel.*

SEIM, in agriculture, a term used by the farmers of Cornwall to express a certain determinate quantity of sea sand, which they use as manure to their lands.

They dredge this up on the sea coasts, and carry it as far toward the lands, where it is to be used, as they can by water. At the landing place the farmers bring a train of horses to receive it, each horse carrying a *seim*, that is a sack of it, containing thirteen gallons. The land carriage of this sand, in Cornwall alone, is supposed to cost thirty two thousand pounds annually; and yet the farmers find abundant encouragement to continue the use of it, it is so rich a manure. Philos. Trans. N° 103.

SEISACHTHEIA, Σεισαχθεια, in antiquity, a public sacrifice at Athens, in memory of Solon's ordinance; whereby the debts of poor people were either entirely remitted, or at least the interest due upon them lessened, and the creditors hindered from seizing upon the persons of their debtors, as had been customary before that time. *Potter*, Archæol. Græc. Tom. I. p. 430.

The word signifies the shaking off a burden.

SEISINA *habenda*, *quia rex habuit annum*, *diem et vastum*, in law, a writ that lies for delivery of *seisin* to the lord of lands or tenements, after the king, in right of his prerogative, hath had the year, day, and waste, on a felony committed. Reg. orig. 166. *Blount*, *Cowel.*

SEITAN, a name given by Avisenna, and other of the Arabian writers, to a species of prickly tree, often recommended in their prescriptions.

The word is sometimes also written *seten*, *sitan*, *setah*, or *setim*.

Pliny mentions this as a wood remarkably durable. He says it grew most plentifully in Egypt, and that it remained uncorrupted in waters. It is called by him, and others of the old Latin writers, *spina nigra*, the black thorn: and the durable nature of our common sloe tree, or black thorn, growing in our hedges, has tempted some to believe it to be the same with the *setin*, or *spina nigra* of the antients; but this is overthrown by the common account of Pliny, and others, of ships being built of this wood, the small size of our black thorn rendering it wholly impossible to put it to such uses.

Theodotion is to be understood of this wood, when he speaks of the *setah*, or *acanthina*.

It is plain from Avisenna, that this *setan*, or *seitan*, is no other than that species of *acacia*, which, from its producing our gum arabic, is called the gum arabic tree. Avisenna calls the fruit of this *alcarad*, or *alcarath*; and in his account of it, he says that it is the fruit of a great thorny tree growing in Egypt, and in the region called Bassera, and that the gum arabic exsudates from its trunk, and the acacia juice is prepared from its fruit alcarath. He adds, that the Ægyptians themselves call it *sitan*; and Prosper Alpinus tells us, that at this time they call it *sant*. This word is easily derived from *sitan*, and then the name is not a little instrumental to the proving what the tree was, as the *sant* is evidently what Avisenna says of the *sitan*, the gum arabic tree.

We find the word *sant* in some of the Arabians also, and they write it *satn*, whence the softer word *sant* is as easily formed, as *botn*, the name of turpentine, is formed into *bont*, or, as some write it, *botin* or *botim*, and many other words in the materia medica of the antients, are spelt in the same manner. *Prosper Alpinus*, de Plant. Ægypt.

SEL, in the materia medica of the antients, a name given to the fruit of an Indian plant, resembling the cucumber in its manner of growth, but bearing a fruit like a pistachia nut.

There are three of these fruits mentioned by the Arabian writers, the *bel*, *sel*, and *fel*. See BEL and FEL.

They tell us expressly that the *bel* and *fel*, as also the fruit *sel*, were not the fruit of a tree, but of a plant, and that of the creeping kind. It is very probable, that the other *fel* of Avisenna is the root of the *nymphæa indica*, which he mentions in the chapter of *nenuphar*, as possessing the same virtues which he attributes to this sort of *fel*, that is the same with those of mandrake.

SELAGINOIDES, in botany, the name of a genus of mosses, the characters of which are these. The capsules are produced in the alæ of the leaves, in the manner of those of the selago, but they are of a different form, being tricoccous, and sometimes quadricoccous, and opening, when mature, into so many valves. See Tab. of Mosses, N° 16.

Of this genus of moss we have only one known species, which is the prickly *selaginoides*, commonly called *feeding mountain moss*. This is found in the mountainous parts of Yorkshire, and in Wales, and loves rocky and moist places. *Dillen.* Hist. Musc. p. 461.

SELAGO, in the Linnæan system of botany, the name of a genus of plants, the characters of which are these. The perianthium is small, and remains after the flower is fallen. It is composed of one leaf, divided into four segments at the edge. The flower consists of one petal, formed into a tube, which is very small, and scarce sensibly perforated, and a limb or verge, which is expanded, and divided into five segments; the two upper of which are the smallest, and the under one the largest of all. The stamina are four capillary filaments, of the length of the flower, into which they are fixed at the base; the two upper ones of these are longer than the rest, and their antheræ are simple. The germen of the pistil is roundish. The style is slender, and of the length of the stamina. The stigma is simple and acute. The flower finally involves the seed, which is single, and of a roundish figure. *Linnæi* Gen. Plant. p. 300.

The characters of this genus of mosses, according to Dillenius, are these. The capsules are produced in the alæ of the leaves, and are either reniform, or globular, and have neither pedicle, operculum, nor calyptra, like the capsules of the other mosses. They have only one cavity, and part into two valves when ripe. To this it may be added that the plants are all rigid and shrubby, and the stalks as well as roots are dichotomous. See Tab. of Mosses, N° 13.

Of this genus of mosses the following are all the known species. 1. The common upright fir moss, or *selago*, resembling the common spruce fir. This grows to four or five inches high, and is found in the crevices of stones, and in some places on the ground, in the mountainous parts of Yorkshire and in Wales. There are three or four varieties of this moss, found in different places, which might lead a new observer into the error of supposing them new species. 2. The American *selago* with notched and reflected leaves. This grows in Pensylvania, in wet clayey soils. 3. The camphorated leaved *selago*, called by some authors the *coris-leaved american moss*. It is found in North America, and its branches are often a foot long, divided at different parts in a dichotomous manner; so that it spreads greatly, taking root all the way that it passes. It generally creeps upon the barks of trees. 4. The coris-leaved *selago*, called by Plumier the *great savin-leaved moss*. This also grows in North America. 5. The toad-flax-leaved *selago*. This also is an American moss, and grows on the trunks and branches of trees. *Dillen.* Hist. Musc. p. 436.

SELANION, in botany, a name by which some authors have called the common *crocus vernus*, or the garden spring flower we call the *crocus*. *Ger.* Emac. Ind. 2.

SELATUS, one of the many names by which the chemical writers have called quicksilver.

SELENÆ, Σεληναι, in antiquity, a kind of cakes ufed in facrifices, and fo called from their being broad and horned, in imitation of the new moon. *Potter*, Tom. I. p. 214.

SELENDERS, in the manege, are chops or mangy fores in the bending of a horfe's hough, as the malenders are in the knees. See MALENDERS.

SELENEUSIACA *terra, earth of Seleneufia*, in the materia medica of the antients, a light fungous earth called by later naturalifts *agaricus mineralis*, and when found in form of powder, or in a difcontinuous ftate, *lac lunæ*.

It is an earth common enough, wherever there are ftone quarries, all over the world; but the fineft ever met with, is that from Sicily, the place where the antient *Seleneufia*, or *Selinus* ftood, and from whence the antient phyficians had it. Some of them have called it the *creta Seleneufiaca*; but all their defcriptions agree in proving it to be this very earth now found there. Diofcorides and Galen mention its remarkable diffufibility in water, and Pliny mentions its melting into a kind of juice, or fmooth homogene fubftance with it; properties fo very applicable to this earth, and fo little fo to any other, as to leave no doubt of their having been originally applied to the very fame fubftance.

The antients gave it internally as an aftringent; but its principal ufe was external, as a cofmetic among the ladies. And Dr. Plot recommends our lac lunæ, on perfonal experience, for the fame purpofes. *Hill*'s Hift. of Foffils, p. 40. See the article AGARICUS *mineralis*.

SELENIACON, a name for a kind of amulet worn for the epilepfy.

SELENITES, (*Cycl.*) in natural hiftory, the name of a large clafs of foffils, the characters of which are thefe. They are bodies compofed of flender, and fcarce vifible filaments, arranged into fine, even, and thin flakes; and thofe difpofed into regular figures, in the feveral different genera, approaching to a rhomboide, or hexangular column, or a rectangled parallellogram: fiffile, like the talcs, but that not only in a horizontal, but alfo in a perpendicular direction: they are flexile in a fmall degree, but not at all elaftic: they do not ferment with acid menftrua, but readily calcine in the fire. See Tab. of Foffils, Clafs 2.

Of this clafs there are feven orders of bodies, and under thofe ten genera. The *felenitæ* of the firft order are thofe compofed of horizontal plates, and approaching to a rhomboidal form. Of the fecond are thofe compofed of horizontal plates, arranged into a columnar and angular form. Of the third are thofe whofe filaments are fcarce vifibly arranged into plates, but which, in the whole maffes, appear rather of a ftriated, than of a tabulated ftructure. Of the fourth are thofe which are flat, but of no determinately angular figure. Of the fifth are thofe formed of plates, perpendicularly arranged. Of the fixth are thofe formed of congeries of plates, arranged into the figure of a ftar. And of the feventh, are thofe of a complex and indeterminate figure. *Hill*'s Hift. of Foff. p. 119, 120.

Of the firft of thefe orders there are three genera. 1. The *leptodecarhombes*. Thefe are thin *felenitæ* of a rhomboidal figure. 2. The *pachodecarhombes*. Thefe are thicker *felenitæ* of a rhomboidal figure. The *felenitæ* of both thefe genera confift of ten planes each. 3. The *tetradecarhombes*. Thefe are *felenitæ* of a rhomboidal figure, but confifting of fourteen inftead of ten planes. See the articles LEPTODECARHOMBES, PACODECARHOMBES, and TETRADECARHOMBES.

Of the fecond order there are alfo three genera. The firft the *ifchnamblluces*. Thefe are *felenitæ* of a flatted columnar octohaedral figure, confifting of fix fides, and two broken ends. 2. The *iamblluces*. Thefe are *felenitæ* of an octohaedral columnar form, but not flatted. 3. The *oxuciæ*. Thefe are *felenitæ* of a columnar form, but not truncated, or with broken ends, but tapering off at each end to a point. See the articles ISCHNAMBLUCIS, &c.

Of the third order there is only one known genus, the *inamblucia*. Thefe are columnar *felenitæ* with abrupt ends, and of a fibrofe, not tabulated texture.

Of the fourth order there is alfo only one known genus, the *fanidia*. Thefe are *felenitæ* of no determinate figure, but of a tabulated ftructure, and refembling the foliaceous tubes. See the articles INAMBLUCIA and SANIDIA.

Of the fifth order there is alfo only one known genus, the *cathetolipes*. Thefe are octohaedral *felenitæ* with perpendicular plates, and obtufe angles. *Hill*'s Hift. of Foff. p. 121, 122, 123.

Of the fixth order there are two genera. 1. The *lepaftra*. Thefe are *felenitæ* compofed of filaments, arranged into plates, and difpofed in form of a ftar. 2. The *trichaftra*. Thefe are *felenitæ* compofed of filaments, fcarce vifibly arranged into plates, but difpofed in threads into the form of a radiated ftar, and appearing merely of a ftriated texture. See the articles LEPASTRA and TRICHESTRA.

Of the feventh order there is only one genus, the *fymplexia*. Thefe are *felenitæ* compofed of various irregularly connected bodies, of the ftructure and general figure of one or other of the former genera. See the article SYMPLEXIUM.

The ftructure of the *felenitæ* of all the genera of the firft order is exactly alike, they are all compofed of a great number of broad flakes or plates, in a great meafure externally refembling the flakes of the foliaceous talcs. Thefe are of the length and breadth of the whole mafs. The top and bottom being each only one fuch plate, and thofe between them, in like manner, each compleat and fingle, and the body may always be eafily and evenly fplit, according to the direction of thefe flakes. Thefe differ, however, extremely from the talcs; for they are each compofed of a number of parallel threads, or filaments, which are ufually difpofed parallelly to the ends. In many of the fpecies they are alfo divided by parallel lines, placed at a confiderable diftance from each other, and the plates in fplitting often break at thefe lines: add to this, that they are not elaftic, and that they readily calcine. *Hill*'s Hift. of Foff. p. 120.

The ftructure of thofe of the fecond order is the fame with that of the firft; but that in many of the fpecimens of them, the filaments, of which the plates are compofed, run in two directions, and meet in an obtufe angle; and in the middle there is generally feen in this cafe a ftrait line, running the whole length of the column, and fmall parcels of clay infinuating themfelves into this crack, reprefent in it the figure of an ear of grafs fo naturally, as to have deceived many into a belief, that there was really an ear of grafs there. The other orders confifting only of fingle genera, the ftructure of each is explained under the generical name. *Hill*'s Hift. of Foff. p. 121. See the articles LEPTODECARHOMBIS, &c.

SELF (*Cycl.*)—SELF *opens*, a term ufed by the miners in the north of England to exprefs certain natural cavities, or chambers, which are frequently met with, fome near the furface, fome at very great depths, fome fmall, and others very large.

Thefe are of various figures, and often run into ftrange finufes. Dr. Lifter, in accounting for the origin of earthquakes, fuppofes the whole cruft of the earth to be more or lefs hollowed in this manner; which he alfo argues for, from the ftreams of waters which arife in large quantities from the fides of mountains, and muft have communication with thefe *felf opens* and fupplies from them.

Thefe natural hollows the doctor thinks to be the means of continuing, and propagating earthquakes; the firft caufe of which he afcribes to the breath of the pyrites, which he alfo fays is the pyrites itfelf *tota fubftantia*. This he obferves takes fire of itfelf, on being expofed to the air in our fight, and may do fo, from various other caufes, underground. The fulphureous fmell of the air and waters, before and after earthquakes, in the places where they happen, feems a proof that they owe their origin to fome fuch fulphureous matter as this ftone; and the rolling, and defultory noife of an earthquake, feems alfo to fhew that it is not expanded every way at once, but is propagated through a chain of thefe fubterranean hollows.

It is not neceffary that we fhould fuppofe a continued chain of them, from the place where the earthquake begins to be felt, to the fpot where it ends; but if there are many of them irregularly fcattered about the earth, the force of the explofion will be fufficient to burft through the folid parts between, and open a paffage from one to the others, which may continue open no longer than the force continues, and after the fhock is over clofe together again, fo as to leave no trace where it was.

Our miners not only find the natural caverns, but they alfo find them often full of what they call *fire damps*, which are inflammable vapours, of the very nature of thofe which occafion earthquakes, and when fired make the fame explofions, and caufe the fame effects in a certain degree. Thefe fometimes require a candle, or other actual fire, to come in contact, in order to kindle them; but fometimes they are found kindled of themfelves, and flaming on the furface of the waters, in the bottoms of the pits, or at the fiffures of the coal. Philof. Tranf. N° 157.

SELI, in botany, a word formed by an abbreviation of the word *fefeli*, and fignifying the fame plant. See the article SESELI.

SELICHA, a name given by the Arabians to a kind of cinnamon. See the article CINNAMUM.

SELIGONION, in botany, a name by which fome authors have called piony. *Ger.* Emac. Ind. 2.

SELION *of land*, *felio terræ*, is derived from the French, *feillon*, which fignifies a ridge of land, or ground arifing between two furrows, and contains no certain quantity, but fometimes more and fometimes lefs. Therefore Crompton fays, that a *felion of land* cannot be in demand, becaufe it is a thing uncertain. *Crompt.* Jurif. 221. Terms of Law.

SELKIE, the name in Zetland for a feal. Many of thefe are found in that ifland. Philof. Tranf. N° 473. fect. 8.

SELL *bed*, in mining, a term ufed in fome parts of England to exprefs fome particularly rich parts of the vein of ore.

In Cornwall they fometimes find the tin ore fo pure, that it requires only bruifing to drefs it, without the wafhing and feparation by grates, launders, and the like means: they call thefe collections of ore the *fell beds* of tin; and it is obferved

ferved that thefe never have any ftrings iffuing from them, as the other lands have. Philof. Tranf. N° 69.

SELLA, among the Romans, a chair in which the old and infirm were carried by fervants through the city, and in journeys. Sometimes the phyficians prefcribed it as an exercife. *Pitifc.* in voc.

SELLA *curulis*, among the Romans. See CURULE *chair*, *Cycl.*

SELLIGA, in the materia medica, a name by which fome authors have called the *nardus Celtica*, or Celtic fpikenard of the fhops. *Ger.* Emac. Ind. 2.

SELLI, Σελλοι, in antiquity, an appellation given to thofe who firft delivered oracles. Thefe, according to Strabo and Euftathius, were men, and the name *felli* is faid to come from *Sellæ*, a town in Epirus, or from the river called by Homer *Selleis*. *Potter*, Archæol. Græc. l. 2. c. 8. Tom. I. p. 267, feq.

SELTZER-*water*, the name of a mineral water of Germany, which arifes near Neider Seltz, and is now ufed in England and many other countries.

We called it *Seltz*, or *Seltzer water*, and the phyficians prefcribe it in many cafes, as fcurveys, fpafmodic affections, and in confumptions; in the laft cafe, mixing it with affe's milk.

Hoffman, in his examination of the principles of this water, obferves, 1. That on the mixing any acid with it, whether it be a weak or a ftrong one, there is an immediate effervefcence; and on the mixing it with Rhenifh wine and fugar, there is a very remarkable emotion and noife, and the whole body of the liquor appears milky for fome time. 2. If they are mixed in equal quantities with fine old Rhenifh wine alone, they become turbid, and acquire a brown colour, with a caft of reddifhnefs; like that produced by mixing oil of tartar, or the urinous fpirit of fal armoniac, with good wine. 3. The tafte of thefe waters is not of that penetrating, fubacid kind, which moft of the other mineral waters are of, but rather has a flavour like that of a diluted folution of a lixivial falt. 4. On putting powder of galls into them, they do not become purple, nor do they blacken the ftools of thofe who drink them. 5. On adding oil of tartar to them they become milky, but throw down no precipitate. 6. A quart of thefe waters gently evaporated, yields a drachm and twelve grains of a faline matter, and this diffolved and filtrated, yields, on a fecond evaporation, two fcruples of a pure alkaline falt. This falt diffolved in water, and added to a folution of corrofive fublimate, precipitates a yellow powder, or turbith mineral; and mixed with an infufion of rhubarb, gives it a reddifh colour; mixed with fal armoniac, it raifes a pungent fmell. 7. A quart of this water being faturated with fpirit of vitriol, to the ceafing of the ebullition on dropping it in, and afterwards gently evaporated, affords a drachm and a half of falt, no way diftinguifhable from tartarum vitriolatum.

8. No medicinal water is fo fubject to fpoil and corrupt as this in the keeping; for which reafon the jars muft be well filled, and nicely fecured with found corks, pitched over. 9. If a quantity of this water be fet for a day or two in an open veffel, it wholly lofes its natural flavour, and taftes only as if oil of tartar had been mixed with common water: in this change it is obfervable alfo, that there is no earthy matter precipitated.

It appears from all thefe obfervations, that this water abounds with an alkaline falt in a much greater quantity, than any other of the known mineral waters; and it feems to contain no particle of the common ingredients of the other mineral waters, which are a ferrugineous earth, and a bitter purging falt, of the nature of Glauber's falt. Hence it does not purge by the belly, but generally goes off by urine. It is one of the mildeft, and moft innocent of all the mineral waters, and may be taken by perfons of the weakeft conftitution. *Hoffman*, Opera, Vol. 5. p. 144.

SEMAMPLEXICAULE *leaf.* See LEAF.

SEMBELLA, among the Romans, a fmall filver coin, equal in value and weight to half the *libella*. *Pitifc.* in voc. See the article LIBELLA.

SEMICIRCULARIS *palpebrarum mufculus*, in anatomy, a name given by Spigelius, and fome others, to one of the mufcles of the face, called by Albinus and Winflow the *mufculus orbicularis palpebrarum*. See MUSCULUS.

SEMI-CUBICAL *parabola*, a curve of the fecond order, wherein the cubes of the ordinates are as the fquares of the abfciffes. Its equation is $a x x = y^3$.

SEMI-DITONUS, in mufic, is ufed by fome writers, as Salinas, for the third minor.

SEMIFLOSCULOUS, in botany, a term ufed to exprefs the flowers of a certain clafs of plants, of which the dandelion, hawkweed, and the like, are kinds.

This fort of flower confifts of a number of *femiflofculi*, which are either difpofed into one or more circles, and all comprehended in the fame cup, which often becomes inverted as the flower ripens. Thefe *femiflofcules* are petals, hollow in their lower part, but in their upper half are flat, and continued in the fhape of a tongue. Thefe are often feparated from each other by intermediate leaves, and are placed upon the embryo fruit, from which there ftands out a flender capillament, divided at the end into two parts; often carried beyond the vagina, fupported by five props. The embryos are placed in the thalamus, or bottom of the cup, and finally become feeds, fometimes winged with down, fometimes naked, fometimes coronated, and fometimes foliated. See Tab. 1. of Botany, Clafs 1. *Tourn.* Inft. p. 467.

SEMI-INTEROSSEUS *indicis*, a fmall fhort flat flefhy mufcle, very like the antithenar, or internal *femi-interoffeus* of the thumb. It is fituated obliquely on one fide of that of the thumb, between the firft phalanx thereof, and the firft metacarpal bone. It is fixed by one end to the outfide of the bafis of the firft phalanx of the thumb, and a little to that bone of the carpus, by which this phalanx is fupported; and by the other end it is fixed near the head of the firft phalanx of the index, on that fide next the thumb. It lies almoft parallel to the antithenar, croffing it a little; this mufcle lying on the convex fide of the hand, and the antithenar on the concave. *Winflow's* Anatomy, p. 202.

SEMILUNARES *cochleæ*, in natural hiftory, the name of a genus of fea fnails, fo called, from their having femicircular mouths. See Tab. of Foffils, Clafs 9. and Tab. of Shells, N° 6.

The characters of the genus are thefe. They are univalve fhells of a compact body, with a flat femicircular, and often dentated mouth. Some of the fpecies have exerted apices, and fome depreffed.

There are many diftinctive and fpecific characters in the feveral fpecies of this genus, which arrange together confiderable numbers of the fpecies under each. Thus the *neritæ*, which are of this genus, are fome of them umbilicated, and others have teeth, and a kind of gums. The *fnail* kinds, diftinctly fo called, that fall under this genus, are very different from the *neritæ*, in that they have no teeth, no gums, and no palate. The term *femilunares cochleæ* was invented by Rumphius to exprefs their mouths, being of the fhape of half of a circle.

Bonani is of opinion that the *neritæ* were fo called, from their being born of the fea, and called by a name expreffive of that origin by way of eminence, as an honour to their watery parent. To make out the juftice of this derivation, it was neceffary to fuppofe the *nerita* more beautiful than other fhells; and in order to give them a claim to this character, the author has introduced into the family of the *neritæ* the trumpet fhells and porcellanes. Some authors have called them *natrices*, from their fwimming, affirming that they fwim in the manner of the nautilus, by fetting their mouths before the wind. This is an opinion as old as Pliny, but it is as erroneous as many others of the opinions of that author. The *neritæ* generally inhabit caverns in the fides of rocks, and ufually ftick faft to the ftone. *Bonani*, Recreat. Ment. et Ocul. p. 56. *Aldrovand.* de Teftac. l. 3. c. 80. *Plin.* l. 9. c. 33.

All the fpecies of the *femilunar* fhells have few convolutions, and have the extremity of the voluta fmall, and ufually ftanding a little out.

The fpecies of the *femilunar cochleæ* are thefe, as arranged under the two general divifions of dentated *neritæ*, and umbilicated *cochleæ*. 1. The dentated *nerita*, commonly called the *gum-fhell*. 2. The bloody tooth-*nerita*. 3. The ox-palate-*nerita*. 4. The ftriated and punctulated *nerita*. This fpecies, when robbed of its outer coat, and polifhed, affumes a very different appearance, and is feen in the cabinets of the curious, under the name of a fafciated *nerita* with black and yellow variegations. 5. The canaliculated *nerita*. 6. The furrowed *nerita*. 7. The thrufh-*nerita*. 8. The partridge-*nerita*.

Of the *neritæ* which have no teeth, the following are the known fpecies. 1. The jafper-*nerita* with a long beak. 2. The jafper-*nerita* with an operculum. 3. The lemon-coloured pea-*nerita*. 4. The yellow pea-*nerita*. 5. The prickly *nerita*. 6. The reticulated *nerita*. 7. The *nerita* variegated with black fpots. 8. The red and white fafciated *nerita*. 9. The lightly ftriated green *nerita*. 10. The undulated *nerita*.

Of the umbilicated *fnails*, we have the following fpecies. 1. The long umbilicated *cochlea*. 2. The *cochlea* with an exerted apex. 3. The *cochlea* with a depreffed apex. 4. The tefticulated *cochlea*. 5. The hermit *cochlea*. 6. The umbonated *cochlea*. 7. The fmall nipple *cochlea*. 8. The heavy white *cochlea*. And 9. the orange-coloured *cochlea*. Hift. Naturel. Eclairc. Part 2. p. 256.

SEMIMEMBRANOSUS, in anatomy, a long thin mufcle, partly tendinous, and fituated on the backfide of the thigh, a little toward the infide.

It is fixed above by a ftrong broad tendon, or long aponeurofis, in the irregular obtufe, prominent line, which goes from the acetabulum to the tuberofity of the ifchium, a little above the infertion of the feminervofus, and between thofe of the gemellus inferior, and quadratus; mixing fome fibres with the triceps tertius. From thence it runs down flefhy, in an oblique direction, behind the inner condyle of the os femoris; below which it terminates in a thick tendon, which is inferted in the pofterior and interior fide of the inner condyle of the tibia, by three fhort branches; the firft,

or uppermost of which, goes a little toward the inside, the second more backward, and the third lower down. Before it is inserted, it sends off sometimes an aponeurosis, like that of the biceps. *Winslow's* Anatomy, p. 216.

SEMINAL (*Cycl.*)—SEMINAL *leaves*, two soft, plain, and undivided leaves, that first shoot forth from the greatest part of all sown seeds, and are different from those of the succeeding plant in figure, texture, and all other respects.

SEMINAL *root*, in natural history, a name given by Grew to that part of the seeds of plants, which may otherwise be called the inner body of the seed: this is distributed through the parenchyma of the seed, but is wholly different from it, and distinguished by Dr. Grew from the radicle, which becomes the plant root in its future growth. The parenchyma of the seed is, in some degree, that to the *seminal root*, which the mould or earth is to the plant root, or radicle; and the *seminal root* is to the plant root, what the plant root is to the trunk. *Grew's* Anat. of Plants.

SEMINALIS, in botany, a name by which some authors have called horsetail. *Ger.* Emac. Ind. 2.

SEMINARY, (*Cycl.*) in gardening, the term used for the seed plot, or place allotted for raising plants from seed, and keeping them till they are fit to be removed into the garden, or nursery.

When the *seminary* is intended for trees, it must be large, and of a soil adapted to the generality of the trees intended to be raised in it: but that which is most in use, is for the supply of the flower-garden, and is the place where flowers are to be raised from their seeds, to procure varieties, or, as the florists express it, new flowers; as also for the sowing all the biennial plants, to succeed those which decay in the flower garden.

The *seminary* should always be situated at some distance from the house, and be walled or paled round, and kept under lock and key, to keep out dogs, &c. and to prevent a great deal of damage, that is frequently done by those who are not acquainted with gardening, before they are aware of it. The several directions, for the management of the *seminary*, are to be seen under the names of the several plants intended to be raised in it. *Miller's* Gard. Dict.

SEMINERVOSUS, in anatomy, a name given by Riolan, and some others, to a muscle of the thigh, more generally known by the name of the *semitendinosus*. The French in general, however, call it *le demi nerveux*. Cowper calls it *seminervosus seu semitendinosus*; and Albinus seems to claim the merit of ascertaining its true name of *semitendinosus*.

It is a long muscle, half fleshy and half tendinous, or like a nerve. It is situated a little obliquely on the posterior and inner part of the thigh. It is fixed above to the posterior part of the tuberosity of the ischium, immediately before, and a little more inward than the biceps. It is afterwards fixed by fleshy fibres to the tendons of the biceps, for about the breadth of three fingers, much in the same manner as the coraco-brachialis is fixed to the biceps of the arm. From thence it runs down fleshy toward the lower part of the inside of the thigh, having a sort of tendinous intersection in the inner part of its fleshy portion. Having reached below the middle of the thigh, it terminates in a small long round tendon, which runs down to the inside of the knee, beside that of the gracilis, where it expands in breadth. It is inserted in the inside of the upper part of the tibia, about two or three fingers breadth below the tuberosity of the spine, immediately under the tendon of the gracilis internus, with which it communicates. It has the same oblique form with the gracilis and sartorius, and sends off a like kind of aponeurosis. *Winslow's* Anatomy, p. 215.

SEMINIUM, a term used by the writers on fossils to express a sort of first principle, from which the several figured stones, or, as they are more usually called, the extraneous fossils, are supposed to have their origin.

The generality of the learned world, at this time, suppose these to be the remains of real shells, &c. brought from the sea to the places where they are now found, at the time of the universal deluge. See the article FIGURED *stones*.

But those who dissent from this system pretend, that these fossile bodies, though they exactly represent shells, &c. yet never were in the sea at all, but that their minute first principles, or, to use their own term, their *seminia* have been carried from the sea, through subterranean passages, to the places where we now find the compleat shells, &c. into which they have grown. Langius, who has written expresly on this subject, though he has candidly collected all that has been said in favour of the diluvian system, by the abettors of it, yet is not convinced by those arguments, but rather inclines to the other side of the question, or the rise of such fossils from *seminia*.

The substance of this hypothesis is as follows: that the sensible and perfectly formed seeds, or principles of growth of shell-fishes, and other sea productions, which, yet extremely small and light, is raised from among the flesh of putrid, or at least of dead sea fish of these kinds; and thence, by its extreme lightness, is wafted up and down in the water, and after that is raised among the vapours issuing from that water; and being then received into the air, fluctuate about in that vehicle also, till it is received into the pores or intestines of the earth; and when there, is wafted about by the ascent and motion of the vapours, and a number of other accidents, through the fissures of the several strata; and even through the pores of stone; and that it thus wanders about, at the will of such irregular agents, till in its course it chance to find some bed, or matrix, proper to its growth or expansion, and when received into that it adheres firmly to it, and is no more the sport of the passing exhalations, but remains there, till by the mediation of the subterranean heat its principles of growth are put in action, and its latent plastic power excited. Then they say, that by means of its seminal aura, and the lapidific, or petrifying nature of the place where it lies, all such fluid matter, as is fitted to make a part of its substance, is collected to it, and is petrified, or hardened into stone, and consequently that a stony body is thus found, of the same shape and figure in which a shelly one would have been formed in the sea, where there would have been no petrifying principle to have made it assume the nature of a stone.

The arguments used, in support of this hypothesis, are these. That there are difficulties attending every system, by which men have attempted to account for the finding of sea shells at the tops of mountains; but that this system is liable to less than the others, as it is much more easy to conceive how the *seminia*, or minute first principles of these things, should be carried to such distant and high places, than how the full grown bodies themselves should; and particularly, that it is very difficult to conceive how such large and tender shells, as those of the cornua ammonis, should be carried unhurt to such heights; though not very wonderful, that the *seminium* of such a shell should be carried thither, and there grow into the shape of its parent animal.

The congeries of extremely minute shells, that we find in some places immersed in hard stones, are urged as another argument against the diluvian hypothesis, as it is supposed that their tender structure in that state could never have supported the tossing about in an ocean of waters; and Langius adds to these general arguments two others, from the cornua ammonis of the fossile kingdom, which were in his own possession; the one of which he says was truly in an embryo state, and very incomplete, and the other had a vast number of small shells of other kinds enclosed in it, which he supposes to have grown there. To this he adds the impossibility, as it appears, of certain conchitæ, which are composed of thin laminæ, bearing the dashing of the waters, by which they must have been brought to the places where we find them, without being broken all to pieces, which yet are found whole and unhurt on mountains; and finally, that there occur in some stones the figures of shell-fish, of an uncommon, and even monstrous kind, such as it is supposed never existed in their mutilated or compleated figures in any living state.

These fossile shells are usually found throughout of one and the same substance, and that the most different imaginable from the substance of the living creatures which they represent; and often, though found in pairs, and perfectly closed on all sides, yet when broken they are found full of the substance of the stone in which they lie, and the armature of several kinds of them, particularly of many of the cornua ammonis, is supposed to plead greatly in favour of this hypothesis; as it is not of the nature of, or at all owing to the substance of the matrix, in which they lie, or of the matter of which they are formed, and is therefore to arise solely from the nature of the *seminium*, from which they are formed.

The immense number of the sea shells, as they are called, thus found fossile, is also thought to argue much on this side of the question; as the favourers of this hypothesis suppose that the sea could not, at any one time, have given up such numbers as the earth is stocked with, though there are no limits to the numbers supposed to be raised from *seminia*; and the immense columns of black marble, found in Ireland, and found of such regular joints, are brought as a proof of the possibility of such a formation of fossils as this from *seminia*, which they suppose must have given origin to those pillars.

The system of the deluge, as delivered by Woodward, is the hardest thing for the abettors of this doctrine of the *seminia* to get over; but tho' they affirm that this author's account is contrary to reason, and to the scripture account of that fatal catastrophe, yet it is not easy to account for many things, in regard to fossils, on any other foundation. They observe that as this deluge was universal, all places throughout the earth ought to have been furnished with fossile shells by it; but that this is not the case, since many large tracts of land have none of them. It is usually observed, that the deluge only could carry shells into the heart of mountains; but the assertors of this doctrine affirm, that this may be done according to their system, since the *seminia* of fossils may be as easily sustained in the air, as those of plants and animals, and that they may so be conveyed into the inmost recesses of the earth through pores and cracks, not visible to us: and they say, that when there they do not want a proper

proper nutritious matter, since the stony particles they find there are much of the nature of their natural shells in the sea.

The growth of the fossile shell from its *seminium* is supposed, by these writers, to be instantaneous, not progressive; and the reason they give for this is, that there is abundant matter for the formation of it in readiness altogether. They advance, that it is not at all more difficult for nature to form a shell from such a *seminium* in the earth than in the sea, provided all the necessary requisites are in readiness, which they suppose, in this case, to be plainly the fact; and they disallow the analogy between the formation of these bodies and crystals, because they observe that these are formed from *seminia*, those only from apposition of particles. They also observe that these shells, as they are formed in the earth, can never have been inhabitants of the sea in that form, because they never have any thing truly of the nature of shelly matter about them. This is, however, absolutely an error. The fossile nautili have usually a great deal of the true pearly matter of the shell about them, and all the arguments, given in favour of this strange hypothesis, seem as easily confuted. The reader has an opportunity, however, of examining this system in its full force; and on comparing it with the diluvian system, delivered under the article of FIGURED *stones*, will be able to judge whether the present age be in the right or not, in giving the preference to that system. *Langii* Hist. Lap. Fig.

SEMIORBICULARIS *labiorum*, a name given by Winslow, and others, to the muscle called by Albinus *orbicularis oris*, and by others *constrictor*, and *sphincter labiorum*.

SEMIREVERBERATORY *fire*, in chemistry, a term used to express such a reverberatory fire, in which the flame is only beaten back upon the bottom of the vessel.

SEMIS, among the Romans, the half of the *as*. See the article As, *Cycl.*

SEMISICILICUS, a word used by some pharmaceutic writers to express a drachm.

SEMISIDERATUS, a word used by some for a person struck with a hemiplegia.

SEMI-SOSPIRO, in the Italian music, a little pause, of the eighth part of a bar in common time. See PAUSE, REST, CHARACTER, *Cycl.*

SEMI-SPINALIS, a muscle, called also *transverso-spinalis dorsi*. It is a fleshy mass, which, from all the spinal and transverse apophyses of the back and loins, is extended in distinct fasciculi over the vertebræ themselves.

It is made up, like that of the neck, of several oblique converging muscles, the uppermost of which is fixed below to the third transverse apophysis of the back, and above to the first spinal apophysis. The lowest is fixed below to the third transverse apophysis of the loins, and above the last spinal apophysis of the back. They are divided by anatomists into the external, which are first discovered, and the internal, which lie immediately on the vertebræ. The external, from the first vertebra to the seventh inclusively, appear to be longer than the internal, which are covered by them. *Winslow*'s Anatomy, p. 248.

SEMI-SPINALIS *colli*, a muscle, called also *transverso-spinalis colli*, and taking into its composition all that fleshy mass, which lies between the transverse and spinal apophyses, from the second vertebra of the neck to the middle of the back, under the splenius and complexus major.

It is composed of several oblique converging muscles, which may be divided into external and internal, of which the external are the longest. These are fixed below to the transverse apophyses of the sixth, seventh, eighth, or ninth vertebræ of the back, by tendinous extremities, which as they ascend become fleshy, and mix with each other. Their superior insertions in the neck are six in number, whereof the first, which is tendinous, is in the seventh spinal apophysis, and the others, which are fleshy, are in the five next spinal apophyses. The internal are shorter, and more oblique than the external, and are partly covered by them. They are fixed, by their lower extremities, to the transverse apophyses of the three or four upper vertebræ of the back, and to the oblique apophyses of the four or five lower vertebræ of the neck, and by their other extremities, they are inserted in the six spinal apophyses of the neck. Some of these internal muscles are very short, lying wholly between the spinal apophyses, and the oblique or transverse apophyses next them. *Winslow*'s Anatomy, p. 243.

SEMISPINATUS, (*Cycl.*) in anatomy, a name given by Riolanus, and some others, to the muscle, more generally known by the name of *longissimus dorsi*.

SEMITALES, among the Romans, a name given to the Gods, who were the protectors of roads. See Hist. de l'Acad. des Inscrip. Vol. 2. p. 22.

SEMI-TONE, (*Cycl.*) in music, is of two kinds, distinguished by the addition of greater and less. The first is expressed by the ratio 16 to 15, or $\frac{16}{15}$; and the second by 25 to 24, or $\frac{25}{24}$. These two are so far from being nearly equal, as it is said in the Cyclopædia, from Malcolm, that they differ by a whole enharmonic diesis; which is an interval practicable by the voice [b], and was much in use among the antients, and not unknown even among the modern practitioners [c].—[b See DIESIS. c See Handel's Oratorio of Samson, in the second part of the song, *Return, return, O God of hosts*.]

SEMI-TONE *major*.—The octave contains ten *semi-tones major*, and two dieses, nearly; for the measure of the octave being expressed by the logarithm 1.000000, the *semi-tone major* will be measured by 0.093109. *Euler*, Tent. Nov. Theor. Mus. p. 107. See INTERVAL.

SEMI-TONE *minor*.—The octave contains seventeen *semi-tones minor*, nearly. If the measure of the octave be the logarithm 1.000000, the measure of the *semi-tone minor* will be 0.058894. *Euler*, Tent. Nov. Theor. Mus. p. 107. See the article INTERVAL.

SEMIVULPA, in zoology, a name by which Gesner, and some others, have called the *opossum*. See OPOSSUM.

SEMODIUS, or the sixth part of the amphora. See MODIUS and AMPHORA, *Cycl.*

SEMODIUS, among the Romans, a measure equal to half the modius, or the sixth part of the amphora. See MODIUS and AMPHORA, *Cycl.*

SEMONES, among the antients, a class of Gods that were of a middle nature, between the celestial and terrestrial Gods. Justin Martyr has mistaken one of these for Simon Magus. Mem. de l'Acad. des Inscrip. Vol. I. p. 270.

SEMYDA, in botany, the name of a tree, mentioned by Theophrastus, and by some supposed to be the same with the *betula*, or birch tree, but very erroneously.

Gaza indeed has translated the word by *betula*, and most of the later authors having consulted only the Latin translation, in their references to this author, have taken it upon credit that he meant the birch by this name.

Theophrastus says that the *samyda*, or *semyda*, has a leaf like the walnut tree, only something narrower; now that the *betula*, or birch tree, has no such leaf, every one must know that ever saw it. He says also, that the bark of the *semyda* is variegated. This as little agrees with the *betula*, as the use he says was made of it. It was esteemed the lightest of all woods, and therefore cut out into all things that required strength without much weight. The use of the birch in rods for malefactors, is as old as any thing we know; and had it been the birch that the author was here describing, he would not have omitted this use.

SENA, in botany, the name of a genus of plants, the characters of which are these. The flower is of the rosaceous kind, being usually composed of five petals, disposed in a circular form. The pistil finally becomes a pod of a flatted shape, usually somewhat crooked, and composed of two membranes, between which are lodged seeds, resembling grape stones, and divided from one another by thin partitions. See Tab. 1. of Botany, Class 21.

The species of *sena*, enumerated by Mr. Tournefort, are these. 1. The Alexandrian *sena* with sharp pointed leaves. 2. The Italian *sena* with obtuse leaves. And 3. the privet-leaved American *sena*. *Tourn.* Inst. p. 618.

The purgative virtue of this plant is found, though very different in degree, in infusion, according to the manner in which that infusion is made. In a cold infusion it purges very gently, but this, according to the time it remains in the water, is different in degree; and in a warm infusion it purges much more briskly. It is easy to see from this, that its operation is very difficult to ascertain, since the degree of heat, which it is not easy to reduce to any certainty, makes it stronger or weaker, though the quantity of the medicine be the same, and the variety of its effect depends on the manner in which it is penetrated by the water, which is to dissolve its active principles.

It is observed that the follicles, or pods of *sena*, operate more gently in infusion, than the *sena* itself: the reason of this is, that the texture of these pods is much more firm than that of the leaves, and therefore the water penetrates less into it, and extracts less of its active principles. It is certain that these pods are equally purgative with the leaves, nay every part of the plant is so; the very stalks, or pedicles of the leaves, having as much virtue as the rest, but only requiring a longer time to boil, to communicate it to water, because of their closer texture. See the article INFUSION.

The most certain way, therefore, of giving this medicine is in the form of Mr. Geoffroy's dry extract, which is made of a very strong infusion, evaporated to a dry and pulverisable substance, easily taken, and of no ill taste, and which operates in a very small quantity, one third part containing the virtue of the whole, or nearly so; the nicest calculations shewing, that twenty four grains of the extract, some part of which may be supposed to be earth, or other accidental or useless matter, possesses the virtues of a drachm in substance. Mem. de l'Acad. des Scienc. Par. 1738.

SENATE (*Cycl.*)—It has been a question among the learned how senators were created, and how the vacancies of the *senate* in old Rome were supplied.

Dr. Middleton is of opinion, that the constant and regular supply of the *senate* was from the annual magistrates; who, by virtue of their several offices, acquired an immediate right to sit and vote in that assembly. The usual gradation of these offices was that of quæstor, tribune of the people, ædile,

ædile, prætor, and conſul; which every candidate, in the ordinary forms of the conſtitution, was obliged to take in their order, with this exception only, that he might forego either the tribunate, or the ædileſhip, at his own choice, without a neceſſity of paſſing through them both. *Middleton's* Treat. of Rom. Senate, p. 6. See the articles QUÆSTOR, TRIBUNE, &c.

But though theſe offices gave both an immediate right, and actual entrance into the *ſenate*, yet the ſenatorian character was not eſteemed complete, till the new ſenators had been enrolled by the cenſors at the next luſtrum, or general review of all the orders of the city, which was generally held every five years. Yet this enrolment was but a matter of form, which could not be denied to any of them, except for ſome legal incapacity, or the notoriety of ſome crime, or infamy upon their characters; for which the ſame cenſors could expel, or deprive any other ſenator, of what rank or ſtanding ſoever. *Middleton* of Rom. Sen. p. 8. See the article CENSOR.

M. Vertot ſeems to perplex the queſtion; firſt, by conſidering the authority of the people, and that of the cenſors, as oppoſite and inconſiſtent with each other in the creation of ſenators, whereas they were both of them jointly neceſſary to make the act complete. Secondly, by aſſerting the cenſorian power to be the original and principal in that affair, whereas it was but ſecondary, or miniſterial to the ſovereign prerogative of the people. *Middleton* of Rom. Sen. p. 13.

It has been the opinion of ſome, that under the kings of Rome the choice and nomination of all the ſenators depended wholly on the will of the prince, without any right in the people, either direct or indirect; and the conſuls, who ſucceeded to the kingly power, enjoyed the ſame prerogative, till the creation of the cenſors, who ever after poſſeſſed the ſole and abſolute right of making and unmaking ſenators. But Dr. Middleton is of opinion, that the kings, the conſuls, and the cenſors, acted in this affair but miniſterially, and ſubordinately to the ſupreme will of the people, in whom the proper and abſolute power of creating ſenators always reſided. And the Doctor aſſures us, upon the ſtricteſt ſearch into the ſtate of the preſent queſtion, as it ſtood under the kingly government, he cannot but conclude, from the expreſs teſtimony of the beſt hiſtorians, the concurrence of ſimilar facts, and the probability of the thing itſelf, that the right of chuſing ſenators was originally and conſtitutionally veſted in the people. *Middleton* of Rom. Sen. p. 36.

The ſupreme power at home was in the collective body of the people, yet where haſte perhaps, or ſecrecy was required, and where the determinations of the *ſenate* were ſo juſt and equitable, that the conſent of the people might be preſumed, and taken for granted, the *ſenate* would naturally omit the trouble of calling them from their private affairs, to an unneceſſary attendance on the public; till by repeated omiſſions of this kind, begun at firſt in trivial matters, and proceeding inſenſibly to more ſerious, they acquired a ſpecial juriſdiction and cognizance in many points of great importance, to the excluſion even of the people; who yet, by the laws and conſtitution of the government, had the abſolute dominion over all. For example:

1. They aſſumed to themſelves the guardianſhip and ſuperintendence of the public religion; ſo that no new God could be introduced, nor altar erected, nor the Sibylline books conſulted, without their expreſs order. *Liv.* 9. 46. *Tertull.* Apol. 5. *Cic.* de Div. 54. ib. 1. 48.

2. They held it as their prerogative, to ſettle the number and condition of the foreign provinces, that were annually aſſigned to the magiſtrates, and to declare which of them ſhould be conſular, and which prætorian provinces. *Cic.* pro Dom. 9. Vid. in Vatin. 15.

3. They had the diſtribution of the public treaſure, and all the expences of the government; the appointment of ſtipends to their generals, with the number of their lieutenants and their troops, and the proviſions and cloathing of their armies. *Polyb.* l. 6. 461. *Cic.* pro Balb. 27.

4. They nominated all ambaſſadors ſent from Rome, out of their own body, and received and diſmiſſed all who came from foreign ſtates, with ſuch anſwers as they thought proper. *Cic.* in Vatin. Vid. *Polyb.* 461.

5. They had the right of decreeing all ſupplications, or public thankſgivings, for victories obtained, and of conferring the honour of an ovation, or triumph, with the title of emperor on their victorious generals. *Liv.* 5. 23. *Cic.* Phil. 14. 4, 5.

6. It was their province to inquire into public crimes or treaſons, either in Rome, or the other parts of Italy; and to hear and determine all diſputes among the allied and dependent cities. *Polyb.* 461. *Liv.* 30. 26. *Cic.* Off. 1. 10.

7. They exerciſed a power, not only of interpreting the laws, but of abſolving men from the obligation of them, and even of abrogating them. *Cic.* pro Dom. 27. pro Cornel. 1. pro Leg. Manil. 21. *Val. Maxim.* 8. 15. It. *Cic.* Phil. 5.

8. In the caſe of civil diſſenſions, or dangerous tumults within the city, they could arm the conſuls by a vote with abſolute power, to deſtroy and put to death, without the formality of a trial, all ſuch citizens as were concerned in exciting them. *Salluſt.* de Bell. Catilin. 29. *Cic.* in Cat. 1. 11.

9. They had a power to prorogue, or poſtpone the aſſemblies of the people, to decree the title of king to any prince whom they pleaſed; thanks and praiſe to thoſe who had deſerved them; pardon and reward to enemies, or the diſcoverers of any treaſon; to declare any one an enemy by a vote; and to preſcribe a general change of habit to the city, in caſes of any imminent danger or calamity. *Cic.* Epiſt. ad Att. 4. 16. pro Mur. 25. pro Deiat. 3. Vid. *Liv.* 30. 17. *Salluſt.* Bell. Cat. 30. *Cic.* in Catil. 4. 3. 3. 4. Phil. 11. 12. Ep. Fam. 12. 10. pro Sext. 12. *Middleton*, ibid. p. 118. ſeq.

The tribunes ſoon ſnatched from them that original right, which they had enjoyed from the very foundation of the city, of being the authors, or firſt movers of every thing, which was to be enacted by the people, and excluded them from any ſhare or influence in the aſſemblies of their tribes [d]: and though in the other aſſemblies of the curiæ and the centuries, they ſeemed to have reſerved to them their antient right, yet it was reduced to a mere form, without any real force; for inſtead of being what they had always been, the authors of each particular act, that was to be propoſed to the people's deliberation, they were obliged, by a ſpecial law, to authoriſe every aſſembly of the people, and whatever ſhould be determined in it, even before they had proceeded to any vote [e]. And C. Gracchus afterwards, in his famous tribunate, uſed to boaſt that he had demoliſhed the *ſenate* at once, by transferring to the equeſtrian order the right of judicature in all criminal cauſes, which the *ſenate* had poſſeſſed from the time of the kings [f].—[[d] Vid. *Dionyſ. Hal.* l. 41. 49. *Cic.* pro Planc. 3. [e] *Liv.* 8. 12. [f] *Appian.* de Bell. Civ. l. 1. *Middleton*, ibid. p. 125, ſeq.]

In the early ages of the republic, when the precincts of the city were ſmall, the ſenators were perſonally ſummoned by an apparitor [g]; and ſometimes by a public crier, when their affairs required immediate diſpatch [h]: but the uſual way of calling them, in later days, was by an edict, appointing the time and place, and publiſhed ſeveral days before, that the notice might be more public [i]. Theſe edicts were commonly underſtood to reach no farther than to thoſe who were reſident in Rome, or near it; yet when any extraordinary affair was in agitation, they ſeem to have been publiſhed alſo in the other cities of Italy [k]. If any ſenator refuſed, or neglected to obey this ſummons, the conſul could oblige him to give ſurety for the payment of a certain fine, if the reaſons of his abſence ſhould not be allowed [l]. But from ſixty years of age they were not liable to that penalty, nor obliged to any attendance, but what was voluntary [m].—[[g] *Cic.* de Sen. 16. [h] *Liv.* 3. 38. *App.* Bell. Civ. 1. [i] *Cic.* Phil. 3. 8. [k] *Cic.* de J. Cæſare ad Att. 9. 17. [l] *Liv.* 3. 38. *Cic.* Phil. 1. 5. [m] *Middleton* of Rom. Senate, p. 130, ſeq.]

The *ſenate* could not regularly be aſſembled in any private or profane place, but always in one ſet apart, and ſolemnly conſecrated to that uſe by the rites of augury. *A. Gell.* 14. 7. *Middleton*, ibid. p. 133.

The *ſenate* frequently met in certain curiæ. See CURIA. But their meetings were more commonly held in certain temples, dedicated to particular deities; as in that of Jupiter, Apollo, Mars, Vulcan, Caſtor, Bellona; of Concord, Faith, Virtue, the Earth, &c. *Middleton*, ibid. 134.

Theſe temples, on account of the uſe which the *ſenate* made of them, were called likewiſe *curiæ*; as well as the proper curiæ, or *ſenate* houſes, on account of their ſolemn dedication, are frequently called temples. *A. Gell.* 14. 7. *Cic.* pro Mil. 33. *Alex. Sev.* c. 6.

The *ſenate* uſed to meet on ſome occaſions in the open air, and eſpecially whenever a report was made to them in form, that an ox had ſpoken; which prodigy, as Pliny tells us, was common in the earlier ages. *Liv.* 26. 10. *Plin.* Hiſt. Nat. 8. 45. *Middleton*, ibid. p. 135, ſeq.

On two ſpecial occaſions the *ſenate* was always held without the gates of Rome, either in the temple of Bellona, or of Apollo. 1ſt. For the reception of foreign ambaſſadors; and eſpecially of thoſe who came from enemies, who were not permitted to enter the city. 2dly. To give audience, and tranſact buſineſs with their own generals, who were never allowed to come within the walls, as long as their commiſſion ſubſiſted, and they had the actual command of an army. *Liv.* 34. 43. Id. 42. 36. Id. 36. 39. *Senec.* de Benef. 5. 15. *Middleton*, ibid. p. 137, ſeq.

The *ſenate* met always of courſe on the firſt of January, for the inauguration of the new conſuls, who entered into their office on that day. *Middleton*, ibid. p. 140, ſeq.

The month of February, generally ſpeaking, was reſerved intire by old cuſtom to the *ſenate*, for the particular purpoſes of giving audience to foreign ambaſſadors. *Cic.* ad Frat. 2. 3. *Aſcon.* in Verr. 1. 35. Ep. ad Fra. 2. 12.

In all months, univerſally, there were three days, which ſeem to have been more eſpecially deſtined to the *ſenate*, the kalends, nones, and ides, from the frequent examples found in hiſtory, of its being convened on thoſe days. But Au-

gustus enacted afterwards, that the *senate* should not meet regularly, or of course, except on two days only of each month, the kalends and ides. *Suet*. Aug. 35. *Middleton*, ibid. p. 142.

On their days of meeting, they could not enter upon any business before the sun was risen, nor finish any after it was set; every thing transacted by them, before or after that time, was null and void, and the author of it liable to censure [n]. Whence it became a standing rule, that nothing new should be moved after four o'clock in the afternoon [o].—[[n] *A. Gell*. 14. 7. [o] *Middleton*, ibid. p. 143.]

The *senate*, as has been shewn above, was composed of all the principal magistrates of the city, and of all who had borne the same offices before them; and consisted therefore of several degrees and orders of men, who had each a different rank in it, according to the dignity of the character which he sustained in the republic.

At the head of it sat the two consuls in chairs of state [p]. Manutius thinks that the other magistrates sat next to the consular chair, each according to his rank; the prætors, censors, ædiles, tribunes, quæstors [q]. But Dr. Middleton rather thinks that the consular senators, who, in all ages of the republic, were the leaders and first speakers in the *senate*, used to sit next in order to the consuls; and after them the prætors, and all who were of prætorian dignity, or had been prætors; then the ædiles, the tribunes, and the quæstors, on distinct benches; and on the same bench with each, all who had borne the same offices: but the curule magistrates, as the prætors and ædiles, were perhaps distinguished, at the head of their several benches, by seats somewhat raised, or separated at least from the rest, in the form of our settees, or of that *longa cathedra*, which Juvenal [r] mentions, to denote the curule dignity.—[[p] *Cic*. in Cat. 4. 1. [q] Vid. *Paul Manut*. de Senatu Rom. cap. 9. [r] Sat. 9. 52. *Middleton*, ibid. p. 144, seq.]

All the private senators sat on different benches, and in a different order of precedency, according to the dignity of the magistracies which they had severally borne. First the consulars, then the prætorians, ædilitians, tribunitians, and quæstorians; in which order, and by which titles, they are all enumerated by Cicero [s]. And as this was their order in sitting, so it was the same also in delivering their opinions, when it came to their turn.—[[s] *Cic*. Phil. 13. 13, 14.]

The *senate* being assembled, the consuls, or the magistrate, by whose authority they were summoned, having first taken the auspices, and performed the usual office of religion, by sacrifice and prayer, used to open to them the reasons of their being called together, and propose the subject of that day's deliberation; in which all things divine, or relating to the worship of the Gods, were dispatched preferably to any other business [t]. When the consul had moved any point, with intent to have it debated and carried into a decree, and had spoken upon it himself as long as he thought proper, he proceeded to ask the opinions of the other senators, severally by name, and in their proper order, beginning always with the consulars, and going on to the prætorians, &c. It was the practice originally to ask the prince of the *senate* the first; but that was soon laid aside, and the compliment transferred to any other antient consular, distinguished by his integrity and superior abilities; till in the later ages of the republic, it became an established custom to pay that respect to relations, or particular friends, or to those who were likely to give an opinion the most favourable to their own views and sentiments on the question proposed [u]. But whatever order the consuls observed, in asking opinions on the first of January, when they entered into their office, they generally pursued the same through the rest of the year. Julius Cæsar indeed broke through this rule; for though he had asked Crassus the first, from the beginning of his consulship, yet, upon the marriage of his daughter with Pompey, he gave that priority to his son-in-law, for which, however, he made an apology to the *senate* [w].—[[t] *A. Gell*. 14. 7. [u] Ibid. [w] *Suet*. Jul. Cæsar. 21. *A. Gell*. 4. 10.]

This honour of being asked in an extraordinary manner, and preferably to all others of the same rank, though of superior age or nobility, seems to have been seldom carried farther than to four or five distinguished persons of consular dignity [x]; and the rest were afterwards asked according to their seniority. And this method, as has been said, was observed generally throughout the year, till the election of the future consuls, which was commonly held about the month of August; from which time, it was the constant custom to ask the opinions of the consuls elect, preferably to all others, till they entered into their office, on the first day of January following [y].—[[x] *Cic*. ad Attic. 1. 13. *A. Gell*. 4. 10. [y] *Cic*. Epist. Fam. 8. 4. Vid. It. in Phil. 5. 13. *Middleton*, ibid. p. 149, seq.]

As the consuls elect had this preference given in speaking before all the consulars, so the prætors, and tribunes elect, seem to have had the same, before the rest of their particular orders. Vid. *Sallust*. Bell. Cat. 51, 52. *Cic*. Ep. ad Att. l. 12. 21. It. *Pigh*. Annal.

None were allowed to speak till it came to their turn, excepting the magistrates, who seem to have had a right of speaking on all occasions, whenever they thought fit; and for that reason, perhaps, were not particularly asked, or called upon by the consuls. *Middleton*, ibid. p. 153.

Several different motions might be made, and different questions be referred to the *senate* by different magistrates, in the same meeting [b]. And if any business of importance was expected or desired, which the consuls had omitted to propose, or were unwilling to bring into debate, it was usual for the *senate*, by a sort of general clamour, to call upon them to move it; and upon their refusal, the other magistrates had a right to propound it, even against their will [c]. If any opinion, proposed to them, was thought too general, and to include several distinct articles, some of which might be approved, and others rejected, it was usual to require that it might be divided, and sometimes by a general voice of the assembly calling out *divide*, *divide* [d].—[[b] *Cic*. Phil. 7. 1. [c] *Liv*. 30. 21. *Cic*. Ep. Fam. 10. 16. *Cic*. pro Leg. Man. 19. [d] *Senec*. Epist. 21. *Cic*. Ep. Fam. 1. 2. Vid. *Ascon*. in Orat. pro Mil. 6.]

If in the debate several different opinions had been offered, and each supported by a number of senators, the consul, in the close of it, used to recite them all, that the *senate* might pass a vote separately upon each: but in this he gave what preference he thought fit to that opinion which he most favoured, and sometimes even suppressed such of them, as he wholly disapproved. *Cæs*. Comm. Bell. Civ. 429.

In cases, however, where there appeared to be no difficulty or opposition, decrees were sometimes made, without any opinion being asked or delivered upon them. *Cic*. Phil. 1. 1.

When any question was put to the vote, it was determined always by a division, or separation of the opposite parties, to different parts of the *senate* house; the consul, or presiding magistrate, having first given order for it in this form: *Let those, who are of such an opinion, pass over to that side; those, who think differently, to this*. *Fest*. in voc. *Cic*. Ep. Fam. 1. 2.

What the majority of them approved was drawn up into a decree, which was generally conceived in words prepared and dictated by the first mover of the question, or the principal speaker in favour of it; who, after he had spoken what he thought sufficient to recommend it to the *senate*, used to conclude his speech, by summing up his opinion in the form of such a decree as he desired to obtain [e]. Which decree, when confirmed by the *senate*, was always signed and attested by a number of senators, who chose to attend thro' the whole process of it, for the sake of adding their names to it, as a testimony of their particular approbation of the thing, as well as of respect to the person, by whose authority, or in whose favour it was drawn [f].—[[e] Vid. *Cic*. Philip. 3. 5. 89. x. 13. 14. [f] *Cic*. Ep. Fam. 15. 6. It. 8. 8. *Middleton*, ibid. 156, seq.]

When the *senate* appeared to be disposed, and ready to pass a decree, it was in the power of any one of the ten tribunes of the people to intercede, that is, to over-rule it. See the article INTERCESSION.

In all cases, where the determinations of the *senate* were over-ruled by the negative of a tribune, of which there are numberless instances, if the *senate* was unanimous, or generally inclined to the decree so inhibited, they usually passed a vote to the same purpose, and in the same words, which was called *an authority of the senate*, and was entered into their journals. *Cic*. Ep. Fam. 1. 2. *Liv*. 4. 57. Vid. *Dio*. 55. 550. See SENATUS *auctoritas*.

In order to deter any magistrate from acting factiously and arbitrarily, in affairs of importance, they often made it part of the decree, which they were going to enact, that if any one attempted to obstruct it, he should be deemed to act against the interest of the republic [g]. Yet this clause had seldom any effect on the hardy tribunes, who used to apply their negative in defiance of it as freely, as on any other more indifferent occasion [h].—[[g] *Cic*. Ep. Fam. 88. ad Att. 4. 2. [h] *Middleton*, ibid. p. 160, seq.]

The factious, and leaders of parties, had several arts of obstructing, or postponing a decree, by many pretexts and impediments which they could throw in its way. Sometimes they alledged scruples of religion, that the auspices were not favourable, or not rightly taken; which, if confirmed by the augurs, put a stop to the business for that day [i]. At other times, they urged some pretended admonition from the Sibylline books, which were then to be consulted and interpreted to a sense, that served their purpose [k]. But the most common method was to wast the day, by speaking for two or three hours successively, so as to leave no time to finish the affair in that meeting: yet when some of the more turbulent magistrates were grossly abusing this right, against the general inclination of the assembly, the senators were sometimes so impatient as to silence them, as it were, by force, and to disturb them in such a manner, by their clamour and hissing, as to oblige them to desist [l].—[[i] *Cic*. Ep. Fam. 10. 12. [k] *Dio*. 39. p. 98. *Cic*. ad Fra. 2. 2. *Cic*. Ep. Fam. 1. 1. [l] *A. Gell*. 4. 10. *Cic*. ad Att. 4. 2. *Middleton*, ibid. 162, seq.]

It seems probable that a certain number of senators was required by law, as necessary to legitimate any act, and give force to a decree: yet there is no certain number specified by any of the old writers, except in one or two particular cases. *Middleton*, ibid. p. 164, seq.

The decrees of the *senate* were usually published, and openly read to the people soon after they were passed; and an authentic copy of them was always deposited in the public treasury of the city, or otherwise they were not considered as legal or valid. *Cic.* Phil. 5. 4. *Tacit.* Ann. 3. 51. *Middleton*, ibid. p. 166, seq.

As to the force of these decrees, it is difficult to define precisely what it was. It is certain that they were not considered as laws, but seem to have been designed originally as the ground-work, or preparatory step to a law, with a sort of provisional force, till a law of the same tenor should be enacted in form by the people; for in all ages of the republic, no law was ever made, but by the general suffrage of the people. *Middleton*, ibid. p. 167, seq.

Even under the kings, the collective body of the people was the real sovereign of Rome, and the dernier resort in all cases. But their power, though supreme and final, was yet qualified by this check, that they could not regularly enact any thing, which had not been previously considered and approved of by the *senate* [m]. This indeed continued to be the general way of proceeding in all quiet and regular times, from the beginning of the republic to the end of it: and the constant style of the old writers, in their accounts of the public transactions, is, that the *senate* voted or decreed, and the people commanded such and such an act [n].—[[m] *Dionys. Hal.* l. 7. 38. Edit. Oxon. *Middlet.* of Rom. Sen. p. 115. [n] *Liv.* 37. 35. *Middleton*, ibid. p. 117.]

SENATOR (*Cycl.*)—In antient Rome, the number of *senators* is commonly supposed to have been limited to three hundred, from the time of the kings to that of the Gracchi. But this must not be taken too strictly. The senate generally had that number, or thereabouts, and upon any remarkable deficiency, was filled up again to that complement by an extraordinary creation. But as the number of the public magistrates increased with the increase of their conquests and dominions, so the number of the senate, which was supplied of course by those magistrates, must be liable also to some variation. Sylla, when it was particularly exhausted, added three hundred to it at once from the equestrian order, which might probably raise the whole number to about five hundred; and in this state it seems to have continued, till the subversion of their liberty by Jul. Cæsar. For Cicero [o], in an account of a particular debate, in one of his letters to Atticus, mentions four hundred and fifteen to have been present at it, which he calls a full house [p].—[[o] Ad Attic. l. 1. 14. [p] *Middlet.* of Rom. Sen. p. 93, seq.]

In antient Rome, a certain age was required for a *senator*, as is often intimated by the old writers, though none of them have expressly signified what it was. The legal age for entring into the military service was settled, by Servius Tullius, at seventeen years [q]; and they were obliged, as Polybius [r] tells us, to serve ten years in the wars, before they could pretend to any civil magistracy. This fixes the proper age of suing for the quæstorship, or the first step of honour, to the twenty eighth year; and as this office gave an admission into the senate, so the generality of the learned seem to have given the same date to the *senatorian* age. Some writers indeed, on the authority of Dion Cassius, have imagined it to be twenty five years; not reflecting that Dion mentions it there as a regulation only, proposed to Augustus by his favourite, Mæcenas [s]. Dr. Middleton takes the quæstorian age, which was the same with the *senatorian*, to have been thirty years complete [t].—[[q] *A. Gell.* 10. 28. [r] *Polyb.* de Instit. rei milit. l. 6. p. 466. [s] Vid. *Dio.* l. 52. p. 477. *Lips.* de Magistratib. Rom. [t] *Middleton* of Rom. Sen. p. 96.]

The laws concerning the age of magistrates were not very antient; and were made to check the forward ambition of the nobles, and to put all the citizens upon a level in the pursuit of honours [t]. And Livy [u] tells us, that L. Villius, a tribune of the people, was the first who introduced them, A. U. 573, and acquired by it the surname of Annalis [w].—[[t] *Cic.* Phil. 5. 17. [u] Lib. 40. 44. [w] *Middlet.* of Rom. Sen. p. 99.]

There was another qualification also required, as necessary to a *senator*, an estate proper to support his rank, the proportion of which was settled by the law. We may collect from Suetonius, that it was settled at eight hundred sestertia before the reign of Augustus [x], which are computed to amount to between six and seven thousand pounds of our money; and must not be taken, as it is by some, for an annual income, but the whole estate of a *senator*, real and personal, as estimated by the survey and valuation of the censors [y].—[[x] *Sueton.* in Aug. cap. 41. [y] *Middleton*, ibid. p. 100.]

This proportion of wealth may seem perhaps too low, and unequal to the high rank and dignity of a Roman *senator*, but it must be considered only as the lowest to which they could be reduced; for whenever they sunk below it, they forfeited their seats in the senate. *Middlet.* ibid. p. 101.

There was some law also subsisting from the earliest times, concerning the extraction and descent of *senators*, injoining that it should always be ingenuous; and as their morals were to be clear from all vice, so their birth likewise from any stain of base blood. In consequence of which, when Appius Claudius, in his censorship, attempted to introduce the grandsons of freed slaves into the senate, they were all immediately turned out again. *Middleton*, ibid. p. 104.

These are some of the laws by which the censors were obliged to act, in the enrollment of the new, or the omission of old *senators*: and when we read of any left out, without any intimation of their crime, it might probably be for the want of one or other of these legal, or customary qualifications. *Middleton*, ibid. p. 106.

It was from the *senatorian* order alone, that all ambassadors were chosen and sent to foreign states: and when they had occasion to travel abroad, even on their private affairs, they usually obtained from the senate the privilege of a free legation, as it was called; which gave them a right to be treated every where with the honours of an ambassador, and to be furnished on the road with a certain proportion of provisions and necessaries, for themselves and their attendants [b]: and as long as they resided in the Roman provinces, the governors used to assign them a number of lictors, or mace-bearers, to march before them in state, as before the magistrates in Rome [c]. And if they had any law-suit, or cause of property depending in those provinces, they seem to have had a right to require it to be remitted to Rome [d].—[[b] *Cic.* Epist. Fam. 11. 1. It. ad Att. 15. 11. *Cic.* Ep. Fam. 12. 21. *Suet.* in Tiber. 31. [c] *Cic.* Ep. Fam. 12. 21. [d] *Cic.* ibid. 13. 26. *Middleton*, ibid. p. 173, seq.]

At home, likewise, they were distinguished by peculiar honours and privileges; for at the public shews and plays they had particular seats apart, and appropriated to them, in the most commodious part of the theatre [e]: and on all solemn festivals, when sacrifices were offered to Jupiter by the magistrates, they had the sole right of feasting publickly in the capitol, in habits of ceremony, or such as were proper to the offices which they had borne in the city [f].—[[e] *Cic.* pro Clu. 47. Vid. It. *Plutarch.* in Flaminin. p. 380. A. [f] *Suet.* Aug. 35. *A. Gell.* 12. 8. *Dionys.* 55. 554. C. *Middlet.* ibid. 175, seq.]

The peculiar ornament of the *senatorian* tunic was the *latus clavus*, as it was called, being a broad strip of purple sewed upon the forepart of it, and running down the middle of the breast, which was the proper distinction between them and the knights, who wore a much narrower stripe of the same colour, and in the same manner [g]. The fashion also of their shoes was peculiar, and different from that of the rest of the city: this difference appeared in the colour, shape, and ornament of the shoes. The colour of them was black, while others wore them of any colour perhaps, agreeable to their several fancies; the form of them was somewhat like to a short boot, reaching up to the middle of the leg, as they are sometimes seen in antient statues and bas-reliefs; and the proper ornament of them was an half moon sewed, or fastened upon the forepart of them, near the ancle [h].—[[g] *Suet.* Jul. Cæs. 80. *Plin.* Hist. 33. 1. [h] *Juv.* 7. 192. *Hor.* sat. 1. 6. 28. *Middlet.* ibid.]

Consuls, prætors, ædiles, tribunes, &c. during the year of their magistracy, always wore the prætexta, or a gown bordered round with a stripe of purple [i]. In which habit also, as has been signified above, all the rest of the senate, who had already borne those offices, used to assist at the public festivals and solemnities [k].—[[i] *Cic.* post. red. in Sen. 5. [k] *Cic.* Phil. 2. 43. *Senec.* Controv. l. 1. 8. *Middleton*, ibid. p. 176, seq.]

As to other matters, relating to Roman *senators*, see SENATE, *supra*.

SENATUS *auctoritas*. In cases where the determinations of the senate were over-ruled by the negative of a tribune, if the senate was generally inclined to the decree so inhibited, they usually passed a vote to the same purpose, and in the same words, which, instead of a decree, was called *senatus auctoritas*, or the authority of the senate, and was entered into their journals; yet had no other force than to testify the judgment of the senate on that particular question, and to throw the odium of obstructing an useful act on the tribune who hindered it. Vid. *Cic.* Ep. Fam. l. 2. & 8. 8. ad Attic. 4. 2. *Liv.* 4. 57. *Dionys.* 55. 550. *Middlet.* of Rom. Senate, p. 161, 162. See SENATE.

SEND, is used by seamen, when a ship, either at an anchor or under sail, falls with her head, or stern, deep into the trough of the sea, *i. e.* into a hollow made between two waves, or billows. They say she *sends* much that way, whether it be a-head or a-stern.

SENDAL, in our old writers, a kind of thin fine silk, mentioned in the Stat. 2. Rich. II. cap. 1. *Blount.*

SENECIO, *groundsel*, in botany, the name of a genus of plants, the characters of which are these. The flower is of the flosculous kind, being composed of several small floscules, divided into many segments at the ends, and contained in a one-leaved cup; which is first of a cylindric shape, and afterwards of a conic, and is divided into many segments at the

the end, which, as the feed comes to maturity, ufually turn downwards and backwards. The flofcules ftand on embryos, which finally ripen into feeds, winged with down.

The fpecies of *groundfel*, enumerated by Mr. Tournefort, are thefe. 1. The common fmall *groundfel*. 2. The taller *groundfel* with ragwort leaves. 3. The tall, large-leaved American *groundfel*. And 4. the American *groundfel* with bluifh purple flowers. *Tourn.* Inft. p. 456.

The common *groundfel*, taken in a ftrong infufion, is an emetic. It is prefcribed in fmaller dofes in dropfies, jaundices, and hæmorrhages. Externally it is ufed in ointments againft cutaneous foulneffes.

SENECTA *anguium*, the exuviæ, or floughs of ferpents. The fnakes caft their whole fkin, and with it were fuppofed to caft off their age, and be born anew; whence the name of thefe caft fkins. A decoction, or infufion of thefe, is recommended by medical writers againft pains of the ears and eyes; and fome fuperftitious people recommend it to women, to tye about their waftes, to prevent mifcarriages, and about their thighs, in time of labour, to haften delivery.

SENEKA, *rattlefnake-root*. This is a root lately brought into ufe among us, and which feems to deferve very great regard. It is the root of a fpecies of *polygala*, or milkwort, diftinguifhed by Gronovius, in his *Flora Virginica*, under the name of the erect *polygala* with a fimple ftalk, with oval leaves pointed at the end, and with an erect clufter of flowers. We generally call it the *rattlefnake-root*, and the French, from the place whence it comes, *Seneka*. See POLYGALA.

The *root* is perennial, the thicknefs of it is generally about that of a man's little finger. It is four or five inches, or more, in length, and is varioufly contorted and twifted, and divides into many branches, furnifhed with fmall fibres, and with a membranaceous rim running all along it. It is yellowifh on the outfide, and white within; very acrid, and fomewhat bitter to the tafte, and has fomewhat of an aromatic flavour. From this *root* arife numerous ftalks, all fimple, and without branches; fome lie on the ground, others ftand erect. Thefe are ten or twelve inches high, when full grown. The leaves ftand alternately on the ftalks, and the flowers are white, and perfectly like thofe of our own kinds of polygala.

Dr. Tennent, who brought over a vaft quantity of this *root* from America fome years ago, and took great pains to introduce it into practice, praifes it very largely as a diuretic, a diaphoretic, and an alexipharmic, and a very powerful attenuant and refolvent. He fays it will fometimes vomit and purge.

The Indians firft taught the ufe of it to the Europeans: they efteem it a fovereign remedy againft the bite of the *rattlefnake*; and Dr. Tennent affures us that he faw two perfons, who had been bitten by this creature in the month of July, when its poifon is moft fatal, perfectly reftored to health by it.

He afterwards gave it in pleurifies and peripneumonies with great fuccefs, and in all other cafes where the blood is infpiffated. If the firft dofes of it provoke a vomiting, it is not at all the worfe, except in cafes in which the patient is very weak; and in fuch this effect is eafily prevented, by giving fome of the teftaceous powders with it.

In pleurifies it is beft to take away ten ounces of blood, before the entering on the ufe of the medicine; in other cafes no precaution is required, but it is to be given in powder, or tincture, in white wine, and the ordinary drink, during the ufe of it, fhould be marfhmallow tea. *Gronov.* Flora Virgin. p. 80. *Geoffroy*, Mat. Med. Vol. 2. p. 140. *Tennent's* Effay on the Pleurify.

This medicine may be given either in powder or decoction; but Dr. Tennent prefers the decoction, having obferved it to give relief fooner than the powder does. The dofe of the powder is thirty five grains, and he gives at once three fpoonfuls of the decoction, prepared by boiling three ounces of the *root* bruifed in a quart of water to near the half. The dofe is repeated every fix hours. He is alfo fond of this *root* in the rheumatifm, dropfy, and gout, in which laft difeafe, he fays, he has given it with fuccefs. See his letter concerning the *Seneka*, or *rattlefnake-root*.

Meffrs. Lemery, Du Hamel, and Juffieu, vouch for the good effects of the *Seneka-root* in pleurifies, and other inflammatory difeafes. Mem. de l'Acad. des Scienc. 1739.

SENEMBI, in zoology, the name of a fpecies of Brafilian lizard, more commonly known by the name *iguana*. See IGUANA.

SENESCHALLO *et marefhallo quod non teneant placita de libero tenemento*, a writ, directed to the fteward and marfhal of England, inhibiting them to take cognizance of an action in their court that concerns freehold. Reg. Orig. 185, 191. *Blount, Cowel.*

SENORIÆ, in botany, a name by which fome authors have called the bonana-tree, or *mufa fructu breviore*. Jonf. Dendr. p. 143.

SENSITIVE (*Cycl.*)—SENSITIVE *fluid*. Some have imagined a *fenfitive fluid* as the principle that preferves animals from corruption, and to which we owe our fenfation and motion. This animal fluid paffes in the proper nervous tubes to the organs of motion, but is contained in the fibrous coats of the nerves to become an organ of fenfation. This *fenfitive fluid* is, according to Mr. Le Cat, capable of thinking, and is fo modified by the ganglions, that what is lodged in each part, is capable of being impreffed by the object proper to each organ. And from the doctrine concerning this animal fluid, he endeavours to account for moft operations, which are generally faid to depend on the foul. Med. Eff. Edinb. Abrid. Vol. 2. p. 481.

But all thefe attempts to account for fenfation and thought, from the properties of matter, feem to be very defperate undertakings, not to fay abfurd.

SENSITIVE *plant*. This is an herb fufficiently known to the world for its remarkable property of receding from the touch, and giving figns, as it were, of animal life. Philofophers in general have, however, contented themfelves with admiring the fact, without giving themfelves any trouble about the caufe.

Mr. Hook indeed has made fome conjectures about it; but the greateft light, that has been given into the thing, is from the inquiries which Meffrs. Du Fay and Du Hamel, gentlemen of the Academy of Sciences at Paris, concerted together, and afterwards made feparately on different fhrubs, or at different times, that each might be able to correct the errors of the other.

The ftructure of the *fenfitive plant* is this. From the large ftems, or main branches of the whole, there part off feveral other leffer ones, and from thefe there go off others ftill lefs, which by way of diftinction may be called the ribs of the leaves, as they ferve to fupport a number of leaves arranged on each fide, and ftanding on fhort pedicles in pairs, over againft one another. Several other plants have thefe fort of compound leaves, as the caffia, colutea, and the like; and all thefe fhut their leaves together at night, and open them again in the morning, in the fame manner as the *fenfitive plant* does. This periodical opening and fhutting of the leaves is therefore common to many plants, not peculiar to the *fenfitive plant*; but the marvel in this is, that befide having this motion periodical and regular, it is to be brought on at other times, and by accidents, there requiring no more than the touching the *plant* to make it clofe its leaves at any time of the day, which it foon afterwards naturally opens again. This is peculiar to this *plant*, and refembles the action of an animal which had been injured or frighted. A clofe obfervation alfo of the manner in which this is performed, will give many hints toward the finding its caufe. It is a very difficult thing to touch the leaf of a vigorous *fenfitive plant* fo lightly, as not to make it clofe. Its fenfation is extremely delicate, and its large rib or nerve, which runs along its middle, is as it were a hinge, on which the two halves of the leaf move when they turn up on being touched, till they ftand erect, and by that means meet one another. The flighteft touch imaginable gives this motion to the fide of the leaf which is touched, which is communicated immediately to the other fide, or half, and they move together; and if the touch have been a very little rougher, the oppofite leaf on the fame rib receives the impreffion, and clofes up in the fame manner with that which was actually touched.

Nor is this all; for when the two fides of each of thefe leaves move upwards, the pedicle of each half moves upwards at the fame time, and by this means they in fome meafure approach toward each other, and make the angles of their pedicles with the main rib, or ftalk of the compofit leaf, lefs than before; and the total motion of each leaf is compofed of thefe two motions.

If the touch be ftill rougher, the whole arrangement of leaves on the fame rib feel its influence on each fide, and all clofe in the fame manner with the fingle pair in the precedent inftance: and if the touch be yet ftronger than this, the rib itfelf feels it, and attempts to clofe in its way; moving itfelf upwards toward the branch from which it is produced, juft as the fingle pedicles of the leaves did toward it: and if the touch be yet more hard and rough, the very branches have the fenfation propagated to them, and apply themfelves to the main ftem, or trunk of the fhrub, as the fimple leaves did before to their rib, and that rib to the branch; fo that the whole *plant* in this ftate forms itfelf from a very complexly branched figure, into a fort of ftrait cylindric one. That motion which has, of all others, the greateft effect upon this *plant*, is a fhaking one.

Thefe three motions of the *plant* are performed by means of three diftinct and fenfible articulations; the firft that of the fingle leaf to its pedicle, the fecond that of the pedicle to its branch, the third that of the branch to the trunk. The primary motion of all which, is the clofing of the two halves of the leaf upon their rib, which ought alfo to be performed in a fimilar manner, and by a fimilar articulation. This, however, is much lefs vifible than the others.

Thefe motions are wholly independent on one another, as may be proved by experiment. It fhould appear, that if the ftalks are moved and collapfe toward the branches, or thefe toward the trunk, that the leaves, whofe motion is ufually primary to thefe, fhould be affected alfo; yet experiment

ment proves that it is possible to touch the branches in such a manner, as to affect them only, and make them apply themselves to the trunk, while the leaves feel nothing of the touch: but this cannot be, unless the branches are so disposed, as that they can fall to the trunk without suffering their leaves to touch any other part of the *plant* in their passage; because if they do, they immediately become affected. Winds and heavy rains cause the *sensitive plants* to shut up their leaves, while easy showers do not at all affect them: it is plain hence, that the agitation of the *plant* by the wind, and the strokes given by the large and hasty drops of rain, are what cause the contraction.

By whatever accident the *plant* has been made to close its leaves, it always regularly opens them again afterwards. This however requires different times, according to several circumstances, as the time of the day, the season of the year, and the more less or vigorous and healthy state of the *plant*: sometimes this is done in ten minutes, sometimes it requires half an hour. And the manner is not less different than the time; for sometimes the leaves unfold themselves first, and sometimes the branches, whereas sometimes all is done at once, and the whole *plant* seems in motion at a time.

In endeavouring to account for the motions of this *plant*, these gentlemen have conjectured that they are performed by means of a sort of very nice and fine hinges, which communicate one with another by means of very minute and slender cords, which occasion them to act as we see when the *plant* is sufficiently disturbed, and these cords shaken; and what gives a strong probability to this conjecture is, that the decayed and dying leaves of the *plant* perform this motion as regularly and vigorously, as those which are fresh and full of juice. It seems plain, that while the juices are evaporating, and the parenchymatous substance of the leaves drying up, these more solid parts, the lines and cordages, retain their figure; and consequently, if it is by means of these that the motion is always performed, it will be as well performed in these as in the fresher leaves; which could not be the case, were it owing to the juices.

The natural opening and shutting of the leaves of this *plant* at night and morning, are not so fixed but that they are variable also, according to circumstances of place, temperature, &c. In the month of August a *sensitive plant* was carried in a pot out of its usual place into a dark cave, the motion that it received in the carriage shut up its leaves, and they did not open till twenty four hours afterwards. At this time they became moderately open, but were afterwards subject to no changes at night or morning, but remained three days and nights with their leaves in the same moderately open state. At the end of this time they were brought out again into the air, and there recovered their natural periodical motions; shutting every night, and opening every morning, as naturally and as strongly, as if it had not been in this forced state; and while in the cave, it was observed to be very little less affected with the touch than when abroad in the open air.

Repeated experiments have proved, that it is not the light of the day that opens the leaves of this *plant*, nor the darkness of the night that closes them; neither is it the alternate warmth of the day, and cold of the night, that have this effect, since it shuts in nights which are much warmer than the days often are in which it opens; and the encreasing the heat of the place in which it is kept, and marking the encrease or decrease on the thermometer, have been found to have not the least effect, as to its sooner or later opening or shutting its leaves.

The most probable conjecture seems, that it is not great heat, or great cold, such as it can bear, that bring on this effect, but the sudden change from one to the other; and this is confirmed by this experiment, that if one of these *plants* be raised under a glass bell, or case, and the bell or covering be taken off, it immediately closes, even though it be in the middle of the day; and this is also observed, that the more open or exposed the *plant* stands, the more strong and lively are its shutting and opening; and that they are most observable in summer, and much less so, when it is kept in a close stove in winter.

The great heats of summer, when there is open sunshine at noon, affect the *plant* in some degree like cold, causing it to shut up its leaves a little, but never in any very great degree. The *plant*, however, is least of all affected about nine o'clock in the morning, and that is consequently the properest time to make experiments on it. A branch of the *sensitive plant* cut off, and laid by, retains yet its property of shutting up and opening in the morning for some days; and it holds it longer if kept with one end in water, than if left to dry more suddenly.

The leaves only of the *sensitive plant* shut up in the night, not the branches, and if it be touched at this time, the branches are affected in the same manner as in the day, shutting up, or approaching to the stalk or trunk, in the same manner, and often with more force. It is of no consequence what the substance is with which the *plant* is touched, it answers alike to all; but there may be observed a little spot, distinguishable by its paler colour in the articulations of its leaves, where the greatest and nicest sensibility is evidently placed.

The *sensitive plant*, plunged into water, immediately closes its leaves, which is partly owing to the touch, partly to the coldness of the water; afterwards the leaves expand again; and if they are then touched, close again as before, as if in the open air, only that they do it with less force.

If the end of one of the leaves be burned with the flame of a candle, or by a burning glass, or by touching it with hot iron, it closes up in a moment, and the opposite leaf does the same, and after that the whole series of leaves on each side the rib, then the rib itself, then the branch, all do the same, if the burning has been in a sufficient degree. This proves that there is a very nice communication between all the parts of the *plant*, by means of which the burning, which only is applied to the extremity of one leaf, diffuses its influence through every part of the shrub.

If a drop of aquafortis be carefully laid upon a leaf of the *sensitive plant*, so as not to shake it in the least, the leaf does not begin to move till the acrid liquor corrodes the substance of it; but at that time, not only that particular leaf, but all the leaves placed on the same rib, close themselves up. The vapour of burning sulphur has also this effect on many leaves at once, according as they are more or less exposed to it; but a bottle of very acrid and sulphureous spirit of vitriol, placed under the branches unstopped, produces no such effect. The wetting the leaves with spirit of wine, has been observed also to have no effect, nor the rubbing oil of almonds over them; though this last application destroys many *plants*.

A branch of the *plant* was cut away longitudinally, till only a third part of the substance remained, yet it communicated the effects of the touch, in the same manner as before, to those branches which arose lower on the shrub. The transpiration of the *plant* being retarded, is of no effect as to its periodical opening and closing; for one kept under a close glass bell shuts and opens as regularly, night and morning, as when it stands in an open green-house. A branch of it put into the exhausted receiver of an air-pump, is found to have its force of opening and closing up much impaired, but not wholly taken off. Mem. de l'Acad. des Scienc. Par. 1736.

SEPHIROS, a word used by Paracelsus, and his followers, to express a sort of dry and hard impostume, or kind of spurious scirrhus.

SEPHIROTH, a Hebrew word signifying brightnesses; and the cabbalists give the name of *sephiroth* to the most secret parts of their science.

The knowledge of the *sephiroth* is not acquired but with much study and labour, and is the highest step of the contemplative theology. They reckon up ten *sephiroths*, which are sometimes represented by ten different circles, included in each other; and sometimes by the figure of a tree, pretty much like what, in the schools, they call Porphyry's tree, to shew the different categories of ens or being. *Calm.* Dict. Bibl. in voc.

SE PIACE, in the Italian music, signifies that the part it is joined to may be repeated, or not, at pleasure.

SEPS, in zoology, the name of a very peculiar animal of the lizard kind, but seeming as if of a middle nature between that genus and the snakes, and appearing rather a serpent with feet than a lizard. See Tab. of Quadrupeds and Serpents, № 31.

It is a small species; its body is rounded, and its back variegated with longitudinal lines of black. Its eyes are black; it has ears, and a small and very slender tail. What appears most singular in it is, that it has four legs with feet, divided into toes; but these are wholly useless to the creature in its motions, and not at all assisting it in walking. The first pair are placed very near the head, the other by the anus. The scales are laid in a reticulated manner; they are of an oblong figure, approaching to a rhomboides, and laid longitudinally. Its belly is white, with a slight cast of blue, and it has nostrils near the end of the snout. Columna took five living young ones out of the body of one of this species, some of which were included in membranes, and others loose, as is the case in the fœtus found in the viper. *Ray's* Syn. Quad. p. 272.

The bite of the *seps* is said to occasion an instant putrefaction of the flesh of the whole body.

SEPTANA, a word used by the antient physicians for a septenary fever, or one that performs its regular period in seven days.

SEPTARIÆ, in natural history, the name of a large class of fossils, called by some *ludus Helmontii*, and by others the *waxen veins*. They are defined to be fossile bodies not inflammable, nor soluble in water, naturally found in loose detached masses of a moderately firm texture, and dusky hue, divided by several *septa*, or thin partitions, and composed of a sparry matter greatly debased by earth, not giving fire with steel, fermenting with acids, and in great part dissolved by them, and calcining in a moderate fire.

Of this class there are two distinct orders of bodies, and under those six genera. The *septariæ* of the first order are those which are usually found in large masses, of a simple uniform

uniform construction, but divided by large *septa* either into larger and more irregular portions, or into smaller and more equal ones, called *talc*.

Those of the second order are such as are usually found in smaller masses of a crustated structure, formed by various incrustations round a central nucleus, and divided by very thin *septa*.

The genera of the first order are four. 1. Those divided by *septa* of spar, called *secomiæ*. 2. Those divided by *septa* of earthy matter, called *gaiophragmia*. 3. Those divided by *septa* of the matter of the pyrites, called *pyritercia*. And 4. those divided by *septa* of spar, with an admixture of crystal, called *diaugophragmia*. See all these under their several heads.

Of the second order there are only two genera. 1. Those with a short roundish nucleus, enclosed within the body of the mass. And 2. those with a long nucleus, standing out beyond the ends of the mass. *Hill's* History of Fossils, p. 500.

SEPTERION, Σεπτήριον, in antiquity, a Delphic festival, celebrated every ninth year, in memory of Apollo's victory over Python. The chief part of the solemnity was a representation of Python pursued by Apollo. *Potter*, Archæol. Græc. Tom. I. p. 430.

SEPTIMONTIUM, among the Romans, a festival celebrated in December on all the seven hills of Rome; whence also it had this name, being otherwise called *agonalia*. See the article AGONALIA, *Cycl.*

SEQUATUR *sub suo periculo*, a writ that lies when a *summons ad warrantizandum* is awarded, and the sheriff returns, that the party hath nothing whereby he may be summoned; then goes forth an *alias* and a *pluries*; and if he comes not in on the *pluries*, this writ shall issue. Old Nat. Br. 163. *Cowel.*

SEQUESTRATION (*Cycl.*)—SEQUESTRATION, *sequestratio*, in chemistry, a term used by some writers to express separation.

SEQUESTRO *habendo*, a writ judicial for the discharging a *sequestration* of the profits of a church benefice granted by the bishop at the king's commandment, thereby to compel the parson to appear at the suit of another. The parson, upon his appearance, may have this writ for the release of the *sequestration*. Reg. Judic. 36. *Blount*, *Cowel.*

SERACH, in the Turkish military orders, an officer who holds the stirrup of the caia of the janizaries in charge, attends him when he goes out on horseback, and serves him as a messenger on all occasions. After this office he has the title of *chous*; and after he has passed through this, he has the same office under the aga of the janizaries. *Pocock's* Egypt, p. 168.

SERANGODES, a word used originally as an epithet for the pumice stone, and expressing cavernous, spungy, or full of holes. It has been hence used to sinuous ulcers, and to all sorts of things that are cavernous, or of a spungy texture.

SERAGE, in zoology, an English name for a bird of the larus, or gull kind, more usually called the *sea-swallow*, and by authors *sterna*. See STERNA.

SERAPIAS, in the materia medica, the official name of the dried root, called *salep*. *Dale's* Pharm. p. 254.

SERBAJEE, in the Eastern military orders, is a captain in the horse in the service of the grand seignior. *Pocock's* Egypt, p. 166.

SERIANA, in botany, a name given by Plumier to a genus of plants, the same in its generical characters with his *cururu*; both which are comprised by Linnæus under one genus, with the new name *paulinia*. *Plumier*, Gen. 35. See the article PAULINIA.

SERICH, the name of a seed used in the food of the Egyptian coptis. It is produced by an herb called *simsim*, and is pounded and put into oil. In this they dip their bread, which is always new, being baked as often as they eat in small flat cakes. These they eat dipped in this oil with raw onions, or else they break the cakes to pieces, and put them into a syrup of sugar, made when the canes are green. *Pocock's* Egypt, p. 183.

SERICUM, *silk*. See the article SILK.

SERICUM is also a name given by several chemical writers to the flowers of zink raised by sublimation in an inclined open crucible. These flowers are not reducible into zink again, and are of a fibrose texture, and a beautiful bright white colour. This has made them be called also the *philosophic cotton*, and others have named them the *aqua sicca philosophorum*. What has given the greatest confusion, however, in regard to them is, that some writers have chosen to call them talc, and a sort of solution of them in vinegar, oil of talc. Others have restrained the word oil to a genuine oil, separated from a solution of these flowers in vinegar; and have attributed to this oil the power of concentrating metals, and fixing silver, or reducing it to the solidity and weight of gold, and making it, like that metal, soluble only in aqua regia. These, however, are mere chimeras, and this boasted oil is, in reality, no other than the essential oil of the grape, and can have no such properties.

SERINUS, in zoology, the name of a small bird common in Germany and Italy, and called by the Austrians *baerngril*, or *birngryl*. See Tab. of Birds, N° 37.

Its back is of a reddish brown, and its head yellow; the colour being deeper in the male, and paler in the female. The rump is of a beautiful yellowish green, as is also the breast. The belly is white, and the sides have some oblong blackish spots. The tail, and long feathers of the wings, are black, and a little greenish at their extremities. The beak is very thick, strong, and short, and is very sharp at the point. It is kept in cages, and sings very sweetly. *Gesner*, de Avibus. *Aldrovand.* de Avib. lib. 18. cap. 20.

SERMOCINATION, *sermocinatio*, in rhetoric, denotes discourse in general, whether held by a person alone, or in company, and is the same with what is called *dialogism*. See the article DIALOGISM.

SERPEGER, in the manege, was used to denote the riding a horse in a serpentine way, or in a tread with waved turnings, like the posture of a serpent's body; but is now become obsolete.

SERPENT, (*Cycl.*) *serpens*, in zoology, the name of a genus of animals, which Mr. Ray defines to be creatures breathing by means of lungs, having only one ventricle in the heart, having no feet, and having a long body, covered with scales. To which he adds, that in cold seasons they can bear hunger a long time. The greater part of the *serpent* class are poisonous, and dangerous in their bite, leaving a mischievous liquor in the wound made by their tooth, which mixing by this means immediately with the blood, is of fatal consequence; though the whole creature may be eaten with safety, or even the poisonous liquor, which does this mischief in the wound, tasted without hurt.

Notwithstanding that *serpents* respire by means of lungs, they do not take in and discharge their breath by such short intervals as other animals, but what they have once inspired will serve them a long time; for as they are of a cold nature, and their naturally necessary vital warmth very small, they do not require such an eternally renewed supply of that pabulum of vital heat, as those which have more of it; and as with us they lie half the year torpid, and half dead, their vital warmth at that time, like fire smothered under ashes, barely exists, and needs perhaps no more air than what the creature took in at one inspiration, before its laying itself down for the season, which serves it till the life-renewing spring returns.

Serpents, according to Mr. Ray, may be divided into the poisonous and the harmless; the first having long dentes exerti, with poisonous liquors contained at their bottom, which on biting they discharge into the wound; the others wanting these teeth, and this poison.

They may also be divided, in regard to their generation, into the oviparous and viviparous; but this is a less firmly founded distinction than may be supposed, since all *serpents* are truly and properly produced of eggs; and the only difference is, that some deposit their eggs in dung-hills, and the like places, to be hatched by accidental heat; while others retain those eggs to be hatched in their own bodies, and so bring forth living young ones. Of the first kind is the common snake, of the latter the viper. *Ray's* Syn. Quad. et Serp. p. 284. See Tab. of Quadrupeds and Serpents.

SERPENS *bubalinus*. Mr. Cleyer has given a very remarkable account, in the German Ephemerides, of the prodigious size, and voracious appetite of this *serpent*, and its manner of feeding.

This gentleman assures us that they grow to the length of twenty five feet, and are surprisingly daring in attacking large creatures for prey. Their neck, he observes, is so small, in proportion to the creatures they seize, that it is a wonder that they can swallow them whole, which yet experience shews they certainly do, having no power of tearing them to pieces. This gentleman saw a compleat stag taken out of the belly of one of these *snakes*, with all its limbs remaining on; and at another time a wild goat, which had been swallowed in the same manner; and from another a compleat porcupine, a very troublesome morsel; and there was once an instance, in the Molucca islands, of a woman big with child being thus sucked down whole by one of these creatures. *Ray's* Syn. An. p. 333.

The method of their managing their prey is this. When thoroughly lank, lean, and hungry, the *snake* lies in wait for any thing it can seize; he darts out upon the prey, and seizing it with his mouth, winds his body round that of the creature; and this he is able to do with such force, that he will often, in twisting himself firmly round the creature, break the bones within its skin. This he continues, and at the same time is biting with his terrible mouth all the tender parts of the creature, till he has destroyed it; or if it be an animal too strong to be killed by these simple folds, it will drag it to some neighbouring tree, and tying it fast against that, draw its body so forcibly round it, as to crush all its bones to pieces by the help of that solid resisting body. The part it usually seizes with its teeth, at the same time, is the creature's nose, which he bites so forcibly, as not only to stop the breath, but to occasion a discharge of blood, which helps to forward its destruction.

But the most singular attack, ever known to have been made by this creature, is that recorded by the same author, of

of its seizing a buffalo; which it destroyed in the manner above described, though it was a long time about it, and was obliged to have recourse to the method of tying it up to a tree, against which it broke its bones severally, with a noise that was heard to a great distance. When the creature had thus destroyed its prey, it continued breaking of the bones, till there was not one left whole in the body, and the whole resembled a shapeless mass of matter.

The jaws and throat of this, and of the other *serpent* kind, though small and narrow, are prodigiously extensible, and made so by nature for the swallowing these morsels. The *snake*, when the prey lay in this state before it, licked it all over, and covered it thick with its saliva, and that so regularly, that the whole carcase looked as if daubed over with glue. This done, it opened its jaws to a monstrous extent, and sucked in the head of the prey, and continuing incessantly sucking, at length drew down the whole body.

This is a work of time, and very often two or three days are employed in it. And when the animal is thus got down, the *snake* is swelled and bloated up all over with it, and is no longer in a state of offending, or even of defending itself, or so much as running away; and the people of the places where this species is common, well know this, and find it an easy thing to destroy them in this state, and are very happy when they catch one, as their flesh is a very delicate food. Ephem. Germ. Ann. 12. Obs. 7.

SERPENS *marinus*, *sea serpent*, the name of a fish of the eel kind, usually of five or six feet in length, and a furrowed body, continuing all the way of the same thickness, till near the tail. See Tab. of Fishes, N° 12.

Its back is of a dusky yellow, and its belly a shining blue. Its snout is long, slender, and pointed, and the opening of its mouth extremely large. Near the end of the under jaw it has four or five large and sharp teeth, which bend backwards, the rest of the teeth are very small, and stand close together. At the very extremity of the upper jaw it has four very large teeth, and all the rest are small, and like those in the under one; but the largest teeth of all are placed in a row, in the middle of the palate. It has only one pair of fins, which are placed near the gills. The openings of the gills are at a considerable distance from the head, and it is marked with dotted lines down its sides. It is common in the Mediterranean, and its flesh is very fine tasted, but full of small bones. *Willughby*, Hist. Pisc. p. 108.

SERPENS *rubescens*, the *red serpent fish*, in ichthyography, the name of a fish, properly of the tænia kind.

It resembles the common snake in figure, and is of a fine strong red in colour, and marked with oblique lines all down the sides, and long ones from the gills to the tail, one on each side. Its mouth is but small, and its teeth sharp and serrated; and it has all over its back a number of fine capillaments, set at distances from one another, even to the tail, and the same on the belly. Its tail ends in a single fin. *Aldrovand.* de Pisc. lib. 3. cap. 28.

SERPENT-*stones*, a name given by some to the cornua ammonis, a beautiful fossile shell, which resembles a *serpent* coiled up.

These are frequent in many parts of the world, beside the plenty we have of them in England, and elsewhere. The accurate observer, Mr. Harenberg, found prodigious numbers of them on the banks, and among the sand of a river in Germany. He traced this river through its several windings for many miles, and among a great variety of belemnitæ, cornua ammonis, and cochlitæ, of various kinds. He found also great quantities of wood, of recent petrifaction, carrying in it at that time the plain marks of the axe, by which it had been cut from the trees then growing on the shore. The water of this river he found, in a dry season, and when the supplies of its natural springs were not diluted with rains, to be considerably heavier than common water; and many experiments shewed him that it contained ferrugineous, as well as stony particles, in great quantity, whence the petrifactions in it appeared the less wonderful, though many of them of recent date.

Of the cornua ammonis, or *serpent-stones*, he there observed more than thirty different species, and doubts not but there are many more yet unobserved. They lie immersed in a bluish fossile stone, of a soft texture, and fatty appearance. They lie in this in prodigious numbers, and of a great variety of sizes, from the larger known sorts, down to such as could not be seen without very accurate inspection, or the assistance of a microscope. Such as lie in the softest of these stones are soft, like their matrix, and easily crumble to pieces; others are harder. In a piece of this stone, of the bigness of a finger, it is common to find thirty, or more of these fossils; and often they are seen only in form of white specks, too minute to shew their figure, till examined by the microscope. But what is most observable of the cornua ammonis of this place is, that they are often found growing not only to, but into one another, in such a manner, that they cannot be supposed ever to have been inhabited by any living fish, especially the specimen which is pierced by the other. This author is of opinion that they grow, and are formed where they are; and attempts to prove it by affirming, that they have an actual increase in size there in a little time, and that not only if left in their beds, but if taken out, and put into a glass of the water. This is an opinion wholly different from the received one at present in the world, and perhaps will be found erroneous on farther trials. Act. Erudit. 1727. p. 140.

SERPENS *terrenus*, the *earth serpent*, a name given by some of the chemical writers to nitre. It was originally given to the nitre of the antients, a salt very different from that which we call nitre, but it has since been applied also to that salt.

SERPENTS *tongues*. The island of Malta abounds with *glossopetræ*, or the petrified teeth of sharks, which, from their resemblance to a tongue, are by the vulgar supposed to be the tongues of *serpents* turned into stone by some miracle of St. Paul, when he was there. This island abounds not only with these, but with bufonitæ, and vast numbers of other remains of sea productions. These things, notwithstanding their perfect resemblance of the same bodies now found recent in the mouths of living fishes, &c. are by some supposed never to have been real parts of fishes, but to have been formed where they now lie by some lusus of nature, or plastic seeds. This, however, is an idle and absurd opinion; and Agustino Scilla, who has written at large on the fossils of this island, gives a very rational account of their being the real remains of animals, which, according to his system, it is no way wonderful to find there. The universal deluge has doubtless been of power to bring all the fossils we find into the places where we now see them buried, even in the midst of quarries of stone, in the middle of inland countries; but in regard to the island of Malta, which so abounds with them at this time, he supposes that long since the time of the creation, and even without the assistance of the general deluge, it may have been formed out of the sea, and that it appears plainly to have been at first no other than a mass of soft mud, with an immense number of sea shells, teeth of fishes, and other remains of sea animals, mingled among it; and that these subsiding as low as they could among that thickening matter, have made the island what we now find it, that is, a heap of earth with these things, in vast quantities, buried in it, and that at different depths, but principally not far from the surface. Philos. Trans. N° 219. p. 182.

That this collection of matter was occasioned by a flood of some kind, is highly probable, but it is not necessary to have recourse to Noah's flood for it, though that might as well cause it as any other; but it might also be formed by an irruption of the ocean into the Mediterranean, or by an inundation of the Tuscan sea driven by vehement winds, or any other means, that way: and when the origin of this island is thus allowed, it is not to be wondered at, that an immensity of the refuse parts of animals, inhabitants of those waters, should be left in the places where they had time to subside. And though there are found among these teeth, &c. in the island of Malta, great quantities of shells, of such species as are not natives of those seas, this is no objection to the opinion; since it is well known that the winds when violent, as they probably were about the time of the formation of that island, will bring such light bodies as shells a vast way in water.

It is a common observation, that the east, and south-east winds, bring to the coast of Calabria great quantities of beautiful shells, none of which are found living in the seas thereabout. The *bufonitæ*, or toadstones of Malta, are plainly the grinder teeth of the lupus and sargus dentex, as also of the aurata, and several other fish, which have such round teeth in the hinder part of their jaws. The shells found in this island, and other places, are so plainly those of once living animals, that the remains of the body of the fish is plainly to be distinguished in some of them; and in others the lamellæ are laid together, and coated over one another, in the very same manner as in the recent shell fish. Philos. Trans. N° 219. p. 186.

It is objected, that these shells are produced in the places where they lie, because they are found in great clusters together, all of the same kind; but this is no material objection, but is easily solved upon the common principles: for if we suppose a number of dissimilar bodies, several of every kind, to be suspended in the same quantity of water, and that water be put in motion, we shall see them all confusedly blended together, while the motion is violent, but they will, as that becomes more calm, separate themselves, and those of the same nature will, in a great measure, get together, and subside in parcels separately from the rest. Thus if straws, sticks, egg-shells, pebbles, and common cockle-shells, were to be thus shook together, the consequence would be, that in a large tub of water they would naturally each parcel subside together in different parts of the bottom; and though in the neighbourhood of one another, yet the straws would not be mixed with the pebbles, nor the egg-shells with the cockles, any more than it is really found, that the different species of shells are mingled in the earth.

It is to be added alfo, that thefe fhells have fubfided, not in water, but in a thicker fluid, compofed of mud and water, and this has kept them more afunder than common water alone would have done; and we fhall find, on examining the bowels of the earth, that though the fhells, in the fame mafs of earth, or ftone, are generally principally of one kind, yet they are neither always fo, nor perfectly fo, but that often they are confufedly blended among other kinds, and more often have fome few of other fpecies blended among them; as a few cockle-fhells might be among the pebbles, in the familiar inftance mentioned above, and by fome particular accidents, even in that cafe, the whole fet of bodies, excepting the very lighteft, might happen to be blended together.

The mountains of Sicily afford fome few *gloffopetræ*, or *fnakes-tongues*, but they are few in number, and worfe prepared than thofe of the ifland of Malta; which is probably owing to the high ground of thofe mountains being lefs likely to receive the refufe of the fea, and its foil, which is fandy, being lefs fitted to preferve them when there, than the marl, of which the ifland of Malta confifts.

The *echini marini*, or fea eggs, and their fpecies, which are very frequent among the *ferpents-tongues* of Malta, all lie upon the furface of the ground, or near it; whereas the *gloffopetræ* lie deeper, though at no great depth. This is a plain effect of all thefe things having been really animal bodies, and having floated in the mud, of which that ifland was formed; for in this it could not be otherwife, but that the *gloffopetræ*, or *ferpents-tongues*, being heavy, would fubfide in the water; while the light fhells of thefe other animals would float on, or near the furface.

The opinion of thefe bodies growing from feminal principles, is alfo greatly weakened by the fituation of them in the earth. If they grew from feeds, as plants, we fhould doubtlefs fee them, like plants, all bending one way, the points of all upwards, and their roots downward; but on the contrary, both in the ifland of Malta and elfewhere, thefe things are found in the moft different directions imaginable; fome with their bottoms upwards, fome downwards, fome horizontal, and others in all the intermediate angles. Some have fuppofed the *gloffopetræ*, in particular, to grow from roots in the earth, becaufe they ufually have roots different from the other parts, and becaufe they ftick very firmly in the earth at thefe roots, but are very eafily loofened in any other part. It is certain indeed that thefe parts, at the bottom of the *gloffopetræ*, are their roots, and that their fpungy texture was intended for their taking in nourifhment; but this was their ufe when in the head of the fifh, not when in the earth; and the reafon of their adhering more firmly to the earth in this, than in any other part, is only that they are more fpungy and porous here, and that in other parts, where they are fmooth and even, the earth can have no hold of them; but where they are thus rough, as they fubfided with a moift earth like mud about them, they naturally become connected ftrongly to it in drying, as part of it was received into their pores, and not broken from the reft, till by forcing them out afterwards. Philof. Tranf. N° 219. p. 189.

Some affirm that the *gloffopetræ* are natural cryftallizations of falt, and that to this their regular figure is owing; but it is to be anfwered, that their figure is not fo regular as thefe objectors feem to fuppofe, but that there are as many different fhapes of them as there are of teeth, in the different parts of the jaw of the fame fhark, or in the jaws of different fpecies of fharks now found living; and if they were cryftallizations of falt, the whole cryftallization would be of one and the fame furface and texture; which is not the cafe, fince the root, as before obferved, is always very different from the body of the tooth, and the fubftance different in even the various parts of the body. Salts are falts throughout, and a ruby, a cryftal, or a diamond, is the fame in all its parts; but this is not the cafe in the *gloffopetræ*, but they are compofed of a cortical and a medullary part, like the teeth of living fharks: and it is to be obferved, that when any of thefe *gloffopetræ* are found broken, as they frequently are, the fracture is found raw and unaltered, which fhews that it has happened before they came to the place where they are now found, and that they have no growth or vegetation there, to heal or cover it; for if there were, it would be fkinned over, as the wounds of plants and animals always are, when in a perfect ftate and living.

Whenever the *gloffopetræ* are taken carefully up out of the earth in Malta, the marl or earth, which ferved for their bed, is found to contain all their minuteft traces and lineaments, like wax from a feal. This is a proof that the marl was as foft as melted wax when they were put into it, and that they were of their full fize and growth when placed there, not having grown, or had any encreafe in that place.

The apophyfes, or proceffes in the *gloffopetræ*, are alfo a ftrong proof of their being no other than real fharks teeth, fince they exactly anfwer to thofe in the teeth of recent fharks, by which every tooth is received or inferted into its neighbour in the jaw. Nay, whereas fharks teeth are mortifed into one another in fuch a manner, that a man may eafily tell which belongs to each fide, which lie near the throat, and which near the front of the mouth; and whereas in a fhark's mouth, the teeth on the left fide will not fit on the right, nor thofe above ferve below, but that on feeing a recent tooth, a perfon of judgment will be able to fay what part of the mouth it belonged to; fo in the foffile fhark's teeth, or *gloffopetræ*, there is not any one which may not be referred to the particular part of the mouth of the living animal, and could have belonged to no other. *Agustino Scilla*, de Petrifac.

SERPENTINÆ, in natural hiftory, a name given by later authors to the marbles which the antients called *ophitæ*, from their fpots refembling thofe of ferpents. See the article OPHITES.

SERPENTINE, (*Cycl.*) in the manege. A horfe is faid to have a *ferpentine* tongue, if it is always frifking and moving, and fometimes paffing over the bit, inftead of keeping in the void fpace, called the liberty of the tongue.

SERPYLLUM, *mother of thyme*, in botany, the name of a genus of plants, the characters of which are thefe. The flowers and feeds are the fame with thofe of the common thyme, but the ftalks are lower, lefs hard, and lefs woody. The fpecies of *ferpyllum*, enumerated by Mr. Tournefort, are thefe. 1. The broad-leaved hairy *ferpyllum*. 2. The common large *ferpyllum* with purple flowers. 3. The common large *ferpyllum* with white flowers. 4. The common leffer *ferpyllum*. 5. The common leffer *ferpyllum* with white flowers. 6. The common fmall *ferpyllum* with flowers variegated with green and white. 7. The common fmall *ferpyllum* with woolly heads. 8. The citron-fcented *ferpyllum*. 9. The larger citron-fcented *ferpyllum*. 10. The narrow-leaved fmooth *ferpyllum*. 11. The narrow-leaved hairy *ferpyllum*. 12. The loweft thyme-leaved *ferpyllum*. *Tourn.* Inft. p. 197. For the medicinal virtues of *mother of thyme*, fee the article THYMUS.

SERRA-*pifcis*, in zoology, a name given by many authors to the *piftris*, or faw-fifh. *Rondelet*. p. 114. See the article PISTRIS.

SERRA is alfo a name given by Pliny to a fpecies of the baliftes, called by the generality of writers *fcolopax*. It is diftinguifhed by Artedi by the name of the *balifles* with two fpines in the place of the belly fins, and one behind the anus.

SERRATA, a name given by fome of the Roman authors to the plant which the Gauls, according to Pliny, had named *betonica*, and which the Greeks called *ceftrum pfuchrotrophon*, and *priorites*. This was evidently the fame plant with our *ferratula*, or faw-wort. But befide this there was another plant called by this name, and which, according to Pliny, was the *chamædrys* or *germander* of the Greeks. He fays that the *chamædrys* of the Greeks was a plant called by the Latins *trixago*, and by fome *chamedrope* and *teucrion*. He adds, that it had leaves like thofe of mint in fhape, but refembling thofe of the oak in their colour and divifion, and that the flower was purple. He adds, that the leaves were fo nicely ferrated at the edge, that it was fuppofed men had taken the idea of a faw from them.

This author is not however to be abfolutely depended upon, and though he here exprefsly fays that this *ferrata* is the fame with the *chamædrys* of the Greeks, yet he feems to run away from this affertion in his defcription, and to make it the fame with the other *ferrata*. Diofcorides fays nothing of the *chamædrys*, but that its leaves were fmall. And it is much more probable that the world fhould take the idea of a faw from the leaves of the *ferratula*, than from thofe of this plant, they being much lefs nicely denticulated than thofe. So that thofe who have been influenced by Pliny, to fuppofe the *germander* and *ferrata* of the antients to be the fame plant, are in the wrong, though they have the countenance of this fo generally reputed authentic author for it.

SERRATE *flies*, in natural hiftory, a name given by authors to certain flies, diftinguifhed from all the other kinds by their having a weapon, refembling a double faw, placed at the hinder part of the body: this ferves feveral fpecies of them to make holes in the branches of trees, in which they depofit their eggs; but there are fome of them which do not feem to make any ufe of this curious inftrument, though they have it. See ROSE-*fly*.

The *fly* of this kind that lays its eggs on the goofeberry bufh, depofits them only on the furface of the middle rib of the leaf; and the ofier-fly, which is one of this genus, produced from a baftard caterpillar of the ofier, lays its eggs on the intermediate furface of the leaves between the ribs. There appears to be no ufe made of this curious inftrument in the depofiting of thefe eggs, fince they are only laid in rows upon the leaves, and fixed to them by means of a vifcous fluid which covers them. It is a very remarkable property in the eggs of this genus of *flies*, that they grow much larger after they are laid. This is obfervable in the eggs of the common rofe-fly, which are at firft buried in the wood, and by their growth force out the furface into tumours of an oval figure: but in thefe of the ofier-fly it is moft beautifully feen, and the whole growth of the fœtus in them is clearly feen, on examining them at different times of

of their growth, which may be easily done without disturbing them, as they lie naked on the surface of the leaf.

When first laid, these eggs are oblong, perfectly pellucid, and of a whitish colour; in a few days they are perceived to be much larger than at first, and a small yellow speck is seen in each of them: they after this continue to grow larger, till they are of twice the bigness that they were at first, and this yellow spot encreasing, soon begins to put on the oblong form of the false caterpillar, which is to be hatched from it. After some days, there are evidently seen two black spots on one extremity of it, which are the eyes, and after this the growth of the included animal becomes so quick, that in a day or two after, if the egg be examined by holding it against a strong light, the compleat animal may be seen in it, doubled in two in such a manner, that its head and tail are brought to touch. These eggs, when deposited on the leaf, are fixed down to it by so strongly viscous a fluid, that they cannot be taken off without breaking; but there does not appear to have been any aperture made by the saw of the animal in the places where they are laid. It is possible that there might be a small wound made in the leaf under each, which though not capable of receiving the egg, might however serve to pour forth a juice sufficient to keep the egg moist; but these apertures must be very small, if there are any such, since the microscope discovers no traces or remains of them. There seems a plain proof that the egg receives some sort of benefit, and that a very essential one to its preservation, from the juices of the plant on which it is deposited, since if those leaves be pulled off from the plant, and left to dry, the eggs always dry up with them, and perish; whereas, if the ends of these leaves be put into water, and the leaf be by that means preserved fresh and juicy, the creature hatches from it as well, as if it was left upon the tree. It should seem from this that the eggs of these *flies*, when introduced into wounds in the branches of trees, become a sort of grafts, and live on the juices of the plant, and that those on the leaves have the same juices conveyed to them in some other manner. This is certain, that whereas the freshness of the plant is absolutely necessary to the hatching of these eggs, it is not at all so to the eggs of other insects which lay upon them. The butterfly lays its eggs on some particular species of plant, according to its kind; but this is only that the caterpillar, when hatched from it, may have proper food; for if the leaf, or which these eggs are laid, be dried, the eggs nevertheless hatch at their proper period, and shew that the juices of the plant, or its continuing fresh, were of no necessity or use to them. The osier-fly gives yet another difficulty, however, in regard to this system, of the eggs of these *flies* receiving nourishment from the juices of the plant; for it frequently lays several rows of eggs on a leaf, and the eggs in some of these lie two deep: now the question is, in what manner the juices of the plant, so necessary to these eggs, are carried to the upper tow? unless we can solve this, by supposing that the eggs of the under row convey juices to the upper ones, by communications of vessels, where they touch, the solution of this difficulty appears no easy task. *Reaumur*'s Hist. Inf. Vol. 9. p. 164.

SERRATED *leaf*, in botany. See LEAF.

SERRATULA, *saw-wort*, in botany, a name given to several species of *jacea*. See JACCA.

It seems very expresly proved by Dioscorides, Pliny, Antonius Musa, and several other of the antients, that the *betonica*, or, as they sometimes wrote it, *vettonica*, was our *serratula*. They mention its growing in woods, and having leaves deeply sinuated, or cut in, and indented all about the edges, and say it grew in wet shady places. All this agrees very well with our cut-leaved *serratula*, and with the *betonica*, or *vettonica* of the antients. Apuleius confounds the *brittanica antiquorum* with the *betonica*, and says that it has large leaves like the dock.

Pliny and this author seem to have drawn their knowledge from the same source; and if Pliny, though he has not said it, supposed, as this author does, that *betonica* and *brittanica* were the same, it is then no wonder that he says the *betonica* had leaves like a dock, for Dioscorides himself says this of the *brittanica*.

SERRATUS (*Cycl.*)—SERRATUS *major*, in anatomy, a broad, fleshy, and pretty thick muscle, lying on the lateral part of the thorax, between the ribs and scapula, by which it is covered. Its figure is that of an irregular square, its greatest breadth being in the back part, where it terminates by digitations of unequal lengths in a radicated disposition, their extremities describing an arch or curve. From these digitations it is that it has its name.

It is inserted backward in the internal labium of all the basis of the scapula, from the superior to the inferior angle; from thence running forward wholly fleshy, it encreases gradually in breadth, and is inserted in all the true ribs, and often in one or two of the false ones, by the same number of digitations. Though the digitations of this muscle give it a radiated appearance from the scapula to the ribs, yet these radii do not all lie in that disposition, which at first sight one would be apt to imagine. The muscle is made up of two planes, one great, the other small: the small plane looks like a distinct narrow muscle, closely adhering to the superior edge of the great plane. It is fixed by one extremity under the superior angle of the scapula, and by the other to the first rib by a small insertion, and to the second rib by a broad one. This plane is easily seen by turning the scapula forward, having first separated the rhomboides; but when it is turned back, the pectoralis minor being first cut off, this plane does not appear, being covered and hid by the broad one. The broad plane may be divided into two portions, one superior, the other inferior, adhering to each other at their edges.

The superior portion is thin, and takes up about three quarters of the basis of the scapula, reckoning from the superior angle; from thence it contracts by small degrees, and forms two digitations, very like those of the small plane, which they cover by their insertions in the two first true ribs, or in the second and third, and sometimes in all the three. The inferior portion is fixed in the lower quarter of the basis scapulæ, from whence it expands itself by six or seven very long fleshy digitations, which decrease in breadth as they descend, and are inserted in the manner beforementioned, in the six or seven ribs which follow the two first. *Winslow*'s Anatomy, p. 176.

SERRATUS *minor*, in anatomy, a name given by Riolanus to the muscle, more commonly known by the name of the *serratus anticus*. See SERRATUS, *Cycl.*

SERRATUS *posticus superior*, a flat thin muscle, situated on the upper part of the back, fixed on one side by a broad aponeurosis to the lower part of the posterior cervical ligament, and to the spinal apophyses of the two last vertebræ of the neck, and two first of the back; from thence it runs down a little obliquely forward, and is inserted by broad fleshy digitations in the posterior part of the second, third, fourth, and sometimes of the fifth true ribs, near their angles; but sometimes it has no insertion in the second rib. It is covered by the rhomboides, and closely united with it. *Winslow*'s Anatomy, p. 231.

SERRATUS *posticus inferior*, a flat thin muscle, lying on the lower part of the back.

It is fixed in the last spinal apophysis of the back, and in the three first of the loins by a broad aponeurosis; from thence it runs up a little obliquely, and is fixed by fleshy broad digitations in the last four false ribs. Its insertions in the lowest rib are near the cartilage, and in the other three near their angles. It is covered by the latissimus dorsi, to which it adheres very closely, and it covers the sacro-lumbaris, and longissimus dorsi. *Winslow*'s Anatomy, p. 231.

SERTA, *garlands*, among the antients. See the article GARLAND, *Cycl.*

SERTULA *campana*, in botany, a name given by some authors to melilot. *Ger.* Emac. Ind. 2.

SERTULARIA, in botany, the name of a genus of sea plants, comprehending, according to Linnæus, the *corallines* and *acetabulums* of Tournefort, and the *opuntioides* of Boerhaave. The generical character of these plants is, that they are a kind of lithophyta, which are jointed and composed of separate parts, fastened to each other by the ends, in the manner of the gems of a bracelet, or beads of a lady's necklace.

SERVE, in the sea language. To *serve* a rope, is to lay spun yarn, rope yarn, sinnet, a piece of canvas, or the like, upon it, which is rolled fast round about the rope, to keep it from fretting or galling in any place.

SERVITIIS *acquietandis*, a writ judicial that lies for a man distrained for services to one, when he owes and performs them to another, for the acquittal of such services. Reg. Judic. 27. *Blount*, *Cowel.*

SERULA, in zoology, the name of a webfooted sea-bird, a kind of mergus, very common about Venice, and called by Mr. Ray *mergus cirratus fuscus*, the brown crested diver, and supposed to be the *anas longirostra*, or long beaked duck of Gesner.

It is very nearly of the size of the duck; its head, and the upper part of its neck, are of a dusky yellow. The crown of the head is of a much duskier and browner colour than the rest, and has a crest of feathers hanging down from it. Its back is of a brownish hue, with a very faint admixture of grey. Its throat is of a pure white in its upper part, but lower down it is variegated with white, black, and a reddish brown. Its belly is all white. Its beak is slender, and rounded, and is three fingers breadth long. The upper chap is of a brownish green, and the under one red. It terminates in a hooked point, and both chaps are all the way serrated, or notched like the teeth of a saw. The wings are very small and short. *Aldrovand.* Vol. 3. p. 281. *Ray*'s Ornitholog.

SERUM (*Cycl.*)—There have been instances, in which the blood has been found to contain with its coagulum a substance, very different from what we usually understand by the word *serum*. Dr. Stuart has given an account of a man in an inflammatory fever, from whose arm eight ounces of blood was taken, which, when it had stood some time, afforded, instead of *serum*, half its quantity of a white liquor, like

like milk, fwimming on the coagulum. This had no fmell at firft; but being kept for obfervation, after fix days it contracted a fmell like that of rotten eggs; and after ftanding three weeks more, it neither altered its confiftence nor fmell.

If this liquor was chyle, then is chyle a fubftance very different from milk, milk being apt to turn fower, and become thick by keeping, and never contracting the fmell of rotten eggs, as this liquor did. Whether it be not chyle turned putrid, and brought near to purulency by a long circulation in the blood veffels, without being converted into blood, through fome defect in the fanguification, is a queftion not eafily decided. Five days after this being blooded again, the blood was found of the common kind, the *ferum* being a thin pellucid water as ufual. Philofoph. Tranf. Nº 442. p. 290.

SERUM *aluminofum*, *alum-whey*, a form of medicine prefcribed in the late London Pharmacopœia, made of a pint of milk boiled to whey with a quarter of an ounce of alum. *Pemberton's* Lond. Difp. p. 255.

SERWOY, in natural hiftory, a name given by Theodore de Bry, and others, to the animal called by us the *opoffum*, and by the natives of Brafil the *carigueya*. Phil. Tranf. Nº 239. p. 107. See OPOSSUM.

SESAMION, a word ufed by the antients to exprefs a preparation of the *fefamum*, or oily grain. It was a cake made of fefamum, honey, and oil.

SESAMOIDE *bones* (*Cycl.*)—The *fefamoide bones* are very fmall, and have their name from the feed of the *fefamum*, or oily grain, to which they are fuppofed to bear fome refemblance. There are feveral of them found, both in the joints of the toes and fingers. They are for the moft part very fmall, and affixed chiefly to ligaments, and only two of them are large enough to be commonly preferved in fceletons: thefe refemble a large flat oval pearl, and are hollowed on one fide.

They are of about the third of an inch in length, and are half as broad as long. They are connected very near each other, by a fmall fhort ligament, to the bafis of the firft phalanx of the great toe, fo as to flide on each fide of the middle eminence of the double pulley, in the firft metatarfal bone, like two fmall patellæ. Though thefe are generally faftened in fceletons to the firft bone of the metatarfus, they neverthelefs belong only to the firft phalanx of the great toe, as the patella belongs not to the os femoris, but to the tibia. *Winflow's* Anatomy, p. 104.

SESAMOIDES, in botany, the name of a genus of plants, the characters of which are thefe. The flower is wholly the fame in fhape with that of the refeda, but the fruit is very different in the different fpecies: in fome it confifts of feveral horns or capfules, each containing one feed of a kidney-like fhape; and in others it is multicapfular, or ftellated.

The fpecies of *fefamoides*, enumerated by Mr. Tournefort, are thefe. 1. The white-flowered *fefamoides* with hoary leaves. 2. The thick-leaved *fefamoides* with purplifh green flowers. 3. The *fefamoides* with ftellated fruit, called by many the *toad-flax-leaved refeda*. *Tourn.* Inft. p. 424.

SESAMUM, in botany, a name given by fome authors to the *myagrum*, or gold of pleafure. *Volk.* Flor. Norimb. 312.

SESELI, in botany, the name of a genus of plants, the characters of which, according to Linnæus, are thefe. The general umbel is uncertain in figure; the partial ones are very fhort, multiple, and almoft round. There is no general involucrum, and the partial ones are compofed of feveral leaves, of the length of the umbellule, narrow, and pointed. The perianthium is fcarce obfervable. The general corolla is nearly uniform; and the fingle flowers are compofed of five inflexo-cordated, and nearly equal petals. The ftamina are five fubulated filaments. The antheræ are fimple. The germen of the piftil ftands under the receptacle. The ftyles are two, and reflex. The ftigmata are obtufe. The fruit is ovated, fmall, ftriated, and feparable into two parts. The feeds are two in number, oval, convex on one fide, and plane on the other.

Tournefort has referred the fpecies of *fefeli* to the genus of fennel, *fœniculum*, from which, however, they greatly differ, in regard to their involucra. *Linnæi* Gen. Plant. p. 120. See FOENICULUM.

SESELI *feed*, in the materia medica, the name of the feed of a plant, called alfo by fome *libanotis*, and growing three or four feet high, with leaves like fennel, but of a paler green. It is a native of warm climates. The *feed* ought to be chofen moderately large, of a longifh fhape, heavy, clean, and of a greenifh colour, frefh, and of a grateful fmell. It affords, by diftillation, a very large quantity of an effential oil, and is hot and dry. It incides, opens, and difcuffes, and is cephalic, neurotic, pectoral, and nephritic. It is good againft epilepfies, apoplexies, vertigos, and all diforders of the head and nerves. *Lemery's* Dict. of Drugs.

The feeds of the *fefeli creticum* are diuretic, uterine, and good in all diforders of the breaft and lungs. They are given in fuppreffions of urine, and of the menfes, and in all kinds of flatulencies; and are, among the German phyficians, a common ingredient in medicines, intended to promote expectoration.

The feed of the french Hartwort, or *fefeli maffilienfe*, is efteemed of great virtue in difeafes of the head and nerves, in convulfions and epilepfies, and in weakneffes of the fight. It is alfo given in electuaries, intended againft all diforders of the breaft and lungs, in coughs, catarrhs, and afthmas, and in obftructions of the liver. Some have recommended it fingly, as a medicine of great efficacy againft obftructions of the menfes; and Schroder tells us, that it has the credit of being an antidote to the poifon of hemlock.

The common hartwort is poffeffed of the fame fort of virtues with the other two, but its feed is more warm and acrid than that of either of them. It is efteemed a very efficacious remedy in obftructions of the menfes, and in all diforders arifing from indigeftion, crudities, and flatulencies.

SESERINUS, in zoology, a name given by Rondeletius, and fome other authors, to a broad and fhort fea fifh, feeming the fame with the *lampuga* of Italian fifhermen; and defcribed by authors in general, and by this very author in another place, under the name of *ftromateus*. *Willughby*, Hift. Pifc. p. 137. See STROMATEUS.

SESQUITERTIONAL *proportion*. When any number or quantity contains another once and one third, they are *fefquitertional proportionals*.

SESSILE *roots*, among botanifts, fuch tuberous roots as adhere to the bafe of the ftalk. See ROOT.

SESSILE *leaf*, among botanifts. See LEAF.

SETS, a term ufed by the farmers to exprefs the young plants of the white thorn, and other fhrubs, which they ufe to raife their quick, or quick-*fet* hedges.

The white thorn is the beft, of all trees, for this purpofe, and under proper regulations, its *fets* feldom fail of anfwering the farmers utmoft expectations.

The firft thing to be confidered by the perfon, who is about to plant a quick-*fet* hedge, is what nature the land is of where it is to ftand, as whether it be clay, fand, or gravel. It is always proper to take the *fets* from a worfe land, than that they are to be planted on, otherwife they will never grow well. The *fets* are about the thicknefs of a man's thumb, and cut within four or five inches of the ground. If the quick is intended only for a hedge, without a bank or ditch, let the *fets* be planted almoft perpendicular in two rows, at about twelve inches diftance from each other; and if there is to be a ditch and a bank, that is to be firft provided. The ground is to be marked out with a line, and a ditch dug three feet wide at the top, one foot wide at the bottom, and two feet deep. When the ditch is digging, on that fide where the quick is to ftand, let the turf be laid evenly on the ground, with the graffy fide downwards: upon this fome fine mould is to be laid, to bed the quick-*fets* in, and they are to be laid upon it with their ends enclining upwards, and at about twelve inches afunder. They muft be carefully gathered, and fuch as are ftrait, fmooth, and well rooted, are only to be chofen. At every thirty feet there fhould be planted with the *fets* a young oak, afh, or fome other fuch tree, to grow up along with the hedge. When a compleat row of the *fets* is thus laid, cover them with a layer of fine mould, and lay over that another layer of the turf; add upon this a third layer of mould, fo deep, that its furface may be a foot above the row of *fets*: on this bed place another row of the like *fets* at the fame diftances, but placed between the others; cover this as the other, and then make up the bank with the earth dug out of the bottom of the ditch, and on its top fet the dry, or dead hedge: this will fhade the under plantation, and will be a defence till the *fets* are grown up into a live hedge. The ftakes for the dead hedge are to be driven into the bank fo low, as to reach the firm ground, and are to be placed at two feet and a half diftance from one another. Oak ftakes are the beft for this purpofe, and fallow and black thorn are efteemed next to thefe. The fmall bufhes cut from them muft be laid below, but not too thick, that they may fhade the young plantation without fmothering it, and defend its young fhoots from the biting of cattle: the long bufhes are to be laid at top to bind in the ftakes, by interweaving them. To add a farther ftrength to the hedge it may be eddered, as the farmers call it: this is binding the tops of the ftakes with fome fmall long poles, or fticks, on each fide. When this is all done, the ftakes fhould be new drove a little, becaufe the making the hedge, and the eddering it, are apt to loofen them a little.

The young plants muft be conftantly weeded, and great care muft be taken to preferve them from the bitings of cattle, efpecially of fheep. If they have been cropped, or are not found to grow well, it is a good cuftom among the farmers to cut them down to the ground, or within an inch of it, for after this they ufually fend out new roots, and fhoot very vigoroufly. *Mortimer's* Hufbandry.

SET-*bolts*, in a fhip. See BOLTS.

SETACEUS *vermis*, in natural hiftory, a name given by Dr. Lifter to that long and flender water worm, which fo much refembles a horfe-hair, that it has been fuppofed by the vulgar to be an animated hair of that creature.

Thefe

These creatures, supposed to be living hairs, are a peculiar sort of insects, which are bred and nourished within the bodies of other insects, as the worms of the ichneumon flies are in the bodies of the caterpillars.

Aldrovand describes the creature, and tells us it was unknown to the antients, but called *seta aquatica*, and *vermis setarius* by the moderns; either from its figure resembling that of a hair, or from the supposition of its having once been a hair of some animal. We generally suppose it, in the imaginary state of the hair, to have belonged to a horse, but the Germans say it was once the hair of a calf, and call it by a name signifying *vitulus aquaticus*, or the water-calf.

Albertus, an author much reverenced by the common people, has declared that this animal is generated of a hair; and adds, that any hair thrown into a standing water will, in a very little time, obtain life and motion Other authors have dissented from this opinion, and supposed them generated of the fibrous roots of water plants, and others of the parts of grasshoppers fallen into the water. This last opinion is rejected by Aldrovand, as the most improbable of all, yet in reality it comes nearest the truth of any of them. Standing and foul waters are most plentifully stored with them; but they are sometimes found in the clearest and purest springs, and sometimes out of the water, on the leaves of trees and plants, as on the fruit-trees in our gardens, and the elms in hedges. They are from three to five inches long, of the thickness of a large hair, and are brown upon the back, and white under the belly, and the tail is white on every part. *Aldrovand.* de Insect. Phil. Trans. N° 83. See the article AMPHISBÆNA *aquatica*.

SETAH, in botany, a name used by the oldest writers for the acacia. It is an orginal Hebrew word, and is explained by the lexicographers, by a thorn growing in the desert. It is rendered by Theodotion *acantha*, one of the names of the acacia.

SETICAUDÆ, in natural history, a term used to express such flies as have one or more hairs growing out at their tails. There are many species of these, distinguished by their having one, two, or three hairs.

SETINUM, in botany, a name given by some to the larch-tree, and by others to some other trees. The reason of giving it as the name of a tree is, that Dioscorides mentions the agaric as growing on it, according to the accounts of some writers of his time. But it is an error in the copies of that author, that has given rise to this imaginary name of a tree. The author says only, that it grew sometimes on beams, and other timber, when exposed to the weather. He has expressed beams by the word *stelechos*, and transcribers have made this *setinos*, or *setinum*.

This appears not only from some of the old manuscript copies retaining the word properly written, but also by the accounts the Arabians give of this drug. Avisenna and Serapion have both copied the words of this author, and they do not render the word in the original author, signifying the place of growth, or production of the agaric, by the name of any particular tree, but both say that it was formed of the putrefaction of trees and beams of timber, when they had been eaten by worms, or corrupted by wet; and they add from the same author, that the production of agaric seemed like that of the funguses.

From this, and from Pliny's account, it appears that the female agaric of the antients was not a fungus, or any thing like our agaric; but by Dioscorides's description of its texture, and Pliny's account of its giving light like a fire in the night, it appears to have been only a peculiar kind of rotten wood, which they knew by that name. The other, or male agaric, was yet more unlike to ours, it being a root of some kind, and in shape resembling the silphium.

SETSE, in botany, the name of a Chinese tree, called also *chitse*, and much esteemed by the people of that country for its beauty, and for the goodness of its fruit. In the provinces of Cantong and Honan there are whole plains covered with these trees, many of which grow to the size of our wallnut-tree. The fruit ripens every where in the East, where the tree grows, but it is of a much more delicious flavour in some places than in others. The leaves are of the colour and shape of those of the wallnut-tree, only that they are more round at the ends. The fruit is sometimes round, sometimes pointed at one end, sometimes oval, sometimes flat, and not unfrequently composed of two pieces, as it were, and resembling two apples cut and joined together. The rind is always green, never changing yellow or red, and the fruit keeps its freshness all the winter. They are about the size of the orange, and the skin is very tender and thin, and the fruit has a mixed taste of the sharp and the luscious. It is very wholesome and good. Observ. sur les Coutumes de l'Asie. p. 198.

SETTEE, a vessel, very common in the Mediterranean, with one deck, and a very long and sharp prow. They carry, some two masts, some three, without top-masts. Their yards and sails are all like the misen. The least of them are of sixty tons burthen. They serve to transport cannon, and provision for ships of war, and the like.

SETTING, (*Cycl.*) the term used by sportsmen to express a manner of attacking partridges, in order to the taking them, by means of a dog peculiarly trained to that purpose. The *setting*-dog generally used is a long land-spaniel, taught by nature to hunt partridges more than any other game, and in his untaught state running over the fields, in search of them, with an alacrity that is truly wonderful; yet by art this creature is brought under such excellent command, that he will, in the midst of his highest career, attend to the least hem from his master, and stand still to look in his face, and take his orders by the slightest signals; and when he is so near his game, that it is almost in his mouth, he will stand stock still, or lie down on his belly, till his master arrive, and he receives his directions.

The *setting*-dog being taken to the haunt of the partridges, is to be cast off, and sent to range; but he must be made to keep near the sportsman, and not to run wildly on, but to beat all the ground regularly. On being reproved for ranging too wildly and too far, he will keep close the whole day, and at times look up in his master's face to know if he does right or wrong. If in the dog's ranging he stop of a sudden, the sportsman is to make up to him, and as there is certainly game before him, he must be ordered to advance; if he refuse this, and look back and shake his tail, it is a signal that they are close before him, and the sportsman is then to take a circumference, and look with a careless eye before the dog's nose to see where they are, and how they lie; then going up, and staking down one end of the net, he is to command the dog to lie still, and to draw the net gently over the birds, then making in with a noise, he is to spring them, and they will be entangled and taken as they rise. It is a rule with fair sportsmen, when they take a covey in this manner, always to let the cock and hen go.

SETTING *of bricks*. See the article BRICKS.

SETTLING *a deck*, at sea, a term for taking a deck lower than it was at first.

SEVENTH (*Cycl.*)—SEVENTH, in music. In thorough basses the *seventh*, whether double, simple, major, or minor, is marked by a figure of 7; but if it be accidentally flat, or minor, thus, $^b7$, or 7^b. If sharp, or major, thus, $\sharp$ 7, or 7 $\sharp$. Again, if when it is naturally minor, it be marked with a flat, it must be diminished.

Diminished SEVENTH, in music. See the article DIMINISHED *seventh*.

SEVERAL (*Cycl.*)—SEVERAL *inheritance*, in law, an inheritance conveyed, so as to descend, or come to two persons *severally*, by moieties, or other parts.

SEVERAL *tenancy*, *tenura separalis*, a plea, or exception taken to a writ that is laid against two persons as joint tenants, who are *several*. Bro. 273. *Blount*, *Cowel*.

SEVERANCE (*Cycl.*)—SEVERANCE *of corn*. The cutting and carrying it from off the ground; and sometimes the setting out the tithes from the rest of the corn, is called *severance*. 2 Cro. 325.

SEVIL, in the manege. The *sevil* of the branches of a bridle is a nail turned round like a ring, with a large head, made fast in the lower part of the branch, called *gargouille*. See the article BANQUET.

SEVIR, among the Romans, an officer who, according to Pitiscus, commanded a whole wing of horse; tho' others make him only the commander of a troop, *turmis*, a division answering to our regiments.

SEVIRI, were also magistrates in the colonies, so called, from their being six in number. *Pitisc.* in voc.

SEW, in the sea language. When a ship at low water comes to lie on the ground, and to lie dry, they say she is *sewed*; and if she be not quite left dry, they say she *sews* to such a part.

SEWEL-*coronde*, a name given by the natives of Ceylon to a species of cinnamon, which, when chewed, is of a mucilaginous nature, like the cassia: this dries well, and is very firm and hard, and has the appearance of a very fine cinnamon; but it has very little taste, and a disagreeable smell. The natives take advantage of the handsome appearance of this kind of cinnamon, and are very apt to mix it with the good kind, to the great detriment of the buyer. Philos. Transf. N° 409.

SEXANGLE, in geometry, a figure having six sides, and consequently six angles.

SEXTANS, (*Cycl.*) a word used by pharmaceutic writers for the sixth part of a pound, that is, two ounces troy-weight, or sixteen drachms. It is also used by some authors for a sixth part of any other standing weight, or measure.

SEXTERY *lands*, are lands given to a church, &c. for maintenance of the sexton. *Blount*.

SEXTULA, a word used by some pharmaceutic writers to express the sixth part of an ounce, that is, four scruples, or one drachm and one scruple.

SEXTUS *oculi*, in anatomy, a name given by Fallopius to one of the muscles of the eye, called by Albinus, and others, the *obliquus oculi inferior*, and by some the *obliquus oculi brevis*. See the articles OBLIQUUS *inferior*, and EYE.

SEXTUS *thoracis*, in anatomy, a name given by Fallopius, and others, to a muscle, now generally known by the name of the *triangularis sterni*.

SEXUALISTÆ, among botanical authors, thofe who have eftablifhed the claffes of plants upon the differences of the fexes, and parts of fructification in plants, according to the modern method, as Linnæus, &c.

SEXUNX, in pharmacy, the weight of fix ounces, or half a pound troy.

SEYGAR, in the materia medica, a name ufed by fome authors for the nutmeg. *Ger.* Emac. Ind. 2.

SHACKLES, aboard a fhip, are thofe oblong iron rings, bigger at one end than at the other, with which the ports are fhut faft, by thrufting the wooden bar of the port through them. There are alfo a fort of *fhackles* to lift the hatches up with, of a like figure, but fmaller. They are faftened at the corners of the hatches.

SHAD, *alaufa*, in zoology, the name of a fea-fifh of the herring-kind, called alfo the *mother of herrings*, and by fome authors *clupea* and *triffa*, and by the antients *trichis*, or *trichias*. See Tab. of Fifhes, N° 39.

It very much refembles the herring in its general form, but it is flatter and broader, and grows to a cubit long, and four inches broad. It is of the colour of the pilchard, of a bluifh black on the back, and a filvery white on the belly and fides, and the coverings of the gills are fometimes purplifh, and fometimes a little yellow. Near the gills it has alfo on each fide a large black fpot, and five or fix others on each fide, which are fmaller, and placed behind them. Thefe are all moft diftinguifhable when the fifh is fcaled. The fcales are large, and eafily fall off, and are dotted with fmall black fpots at their edges.

It is very common in many feas, and in fome of our large rivers which lie near the fea. They run up thefe in great numbers in the months of March and April, and are then very fat; in May they become lean, and then go down to the fea again. They ufually fwim in large fhoals together. *Willughby*, Hift. Pifc. p. 227.

SHAFT (*Cycl.*)—SHAFT, in mining, is the fame with a groove, or pit. *Shafts* are funk fome ten, fome twenty fathoms deep into the earth, more or lefs. *Houghton*'s Compl. Miner, in the Explan. of the Terms.

SHAGGE, in zoology, a name by which we commonly call a water fowl common on the northern coafts, and called by Mr. Ray *corvus aquaticus minor*, or the leffer cormorant, being properly a bird of the cormorant-kind.

It is fomewhat larger than the common duck, and weighs about four pounds. Its beak is ftrait and flender, and is not flatted, but roundifh. It is four fingers breadth long, and is hooked at the end. Its mouth opens very wide, and its eyes are fmall. Its head, neck, and back are of a fine fhining black, with an admixture of a purplifh, or greenifh glofs, fhining like fattin. Its breaft is brown, and the middle of its belly greyifh. Its tail is fhort, and its wings, when folded, reach juft to the end of it, and no farther. Its legs are covered with a cancellated fkin, not a congeries of fcales, and its toes are all connected by a membrane. It fwims with its head erect, and moft of its body under water, and is very fhy, and with difficulty fhot. It builds in trees as the common cormorant, and is evidently a fpecies of that bird, though different in fize, and in the colour of its belly. *Ray*'s Ornitholog. p. 219.

SHAKER *pigeon*, a kind of pigeons, of which there are two forts, the broad tailed, and the narrow tailed.

The firft is the fineft, and moft valued. It has a beautiful long thin neck, which bends like the neck of a fwan, leaning towards the back. It has a full breaft, a very fhort back, and a tail confifting of a great number of feathers, feldom lefs than four and twenty, which it fpreads in an elegant manner, like the tail of a turkey-cock, and bends it up fo, that it meets the head. It is commonly all white, but fometimes is red, yellow, or blue-pied. The longer the neck of this bird is, the more it is valued.

The fecond, or narrow-tailed *fhaker*, has a fhorter and thicker neck, and a longer back. It is efteemed by many a different fpecies, but feems only a mixed breed with fome other pigeon. They are called *fhakers*, from a tremulous motion which they have with their necks when courting. *Moore*'s Columbarium, p. 54.

SHAMBLE, in mining, a term ufed to exprefs a fort of nich, or landing place, left at certain diftances in the adits of mines. The method of digging the tin mines in Devonfhire, and fome parts of Cornwall, is this; they fink their way in fuch a breadth, as is fufficient for them to ftand and work, and at every fathom they leave a fquare place vacant, to which the ore is to be thrown up with fhovels as it is dug. This they do from caft to caft; that is, as far as a man can conveniently throw up the ore with his fhovel. Thus the ore, as it is dug by the beelmen, is thrown up by the fhovellers, who follow them from *fhamble* to *fhamble*, till it comes to the top of the mine. This, however, is but an inconvenient way, and the ufe of thefe *fhambles* is generally fupplied by a winder at the opening of the mine, which manages two buckets, the one of which is fent down empty, while the other is fent up full; and one man employed below to load, and another above to empty. Phil. Tranf. N° 69. See the article DIGGING.

SHAMBRIER, in the manege, is a long thong of leather, made faft to the end of a cane, in order to animate a horfe, and punifh him, if he refufes to obey the rider.

SHANK *of an anchor*, on board a fhip. See ANCHOR.

SHANK, in the manege, is that part of a horfe's fore leg, which lies between the knee and the fetlock, or paftern-joint.

SHANK, or *Shank-painter*, in a fhip, is a fhort chain faftened under the foremaft-fhrowds, by a bolt, to the fhip's fides, having at the other end a rope faftened to it. On this *fhank-painter* the whole weight of the aft part of the anchor refts, when it lies by the fhip's fide. The rope, by which it is haled up, is made faft about a timber-head.

SHARE, the name of that part of the plough which cuts the ground, and the wood to which it is fixed. The extremity of the iron forwards is called the point of the *fhare*, and the end of the wood behind is called its tail.

The length of the whole *fhare*, from point to tail, fhould be three feet nine inches; at the top of the iron it has an upright piece, called the *fin*, and near the iron, at the other end, there is an oblong fquared hollow, called the *focket*; the ufe of which is to receive the bottom of the fheat. Near the tail there is a thin plate of iron, well rivetted to the wood; by means of this plate the tail of the *fhare* is held firmly to the hinder fheat of the plough by a fmall iron pin, with a fkrew at the end, and a nut fkrewed on it, on the inner or right fide of the fheat.

The point of the *fhare* is that part in which it does not run up into the fin: this point is generally made of three inches and a half in length, and fhould be flat underneath, and round at the top, and the lower part of it muft be of hard fteel. The edge of the fin fhould alfo be well fteeled, and fhould make an acute angle with the *fhare*.

The focket is a fort of mortife; it fhould be a foot long, and about two inches deep: the fore end of it muft not be perpendicular, but oblique, conformable to the end of the fheat which enters into it. The upper edge of the fore part muft be always made to bear againft the fheat; but if this end of the focket fhould not be quite fo oblique as the fheat, it may be helped, by paring off a fmall part of the wood at the point. *Tull*'s Hufbandry, p. 140. See the article PLOUGH.

SHARK. We know two different fifh under the fame name of *fhark*, with the addition of their colour, blue and white. See Tab. of Fifhes, N° 2, 3, 4.

The blue *fhark* is that fpecies of fqualus called *glaucus*, and *galeus glaucus*, by authors, and diftinguifhed by Artedi by the name of the *fqualus* with a triangular dent, or furrow, in the extremity of the back, and with no foramina about the eyes. See GALEUS.

The other is the *lamia*, or *canis carcharias* of authors, commonly called by us fimply *the fhark*. This is diftinguifhed by Artedi by the name of the *fqualus* with a flat back, and with numerous teeth, ferrated at the edges. See the article SQUALUS.

The white *fhark*, or *lamia*, is a very dreadful and voracious fifh, the largeft of all the *fharks*. They have been feen of four thoufand weight, with throats capable of fwallowing a lufty man whole; nay, men have been found whole in them when opened. Some have, for this reafon, imagined this, and not the whale, to have been the fifh in whofe belly the prophet Jonah lay. Its teeth are very fharp and terrible; they are difpofed in fix rows, and are all triangular, and notched like a faw on their edges. Thefe are, in the whole, a hundred and forty four in number, and are placed in various directions. Their number is not exactly determinate. Its back is fhort and broad, in comparifon of the other fifh of this kind, and its tail compofed of two fins of a cubit in length each. Its fkin is rough, and its eyes large and round. It is found both in the Ocean and Mediterranean, and is of all fifh the moft voracious of human flefh.

It has its name from the Greek, λαίμος, a voracious feeder, or glutton. The foffile bodies, called *gloffopetræ*, or ferpents tongues, and fuppofed to be real ftones, are the teeth of this fifh. *Willughby*, Hift. Pifc. p. 47.

Hammer-headed SHARK. See the article ZYGÆNA.

SHARP (*Cycl.*)—SHARP, in the fea language, is to hale taut. Thus when they fay, *fharp the bow line*, it fignifies to hale it taut.

SHARP *third*, in mufic, the third major. See the article INTERVAL.

SHARPLING, in ichthyology, the Englifh name of the gafterofteus. See GASTEROSTEUS.

SHASTRAM, the name of the bible of the Bramins. See the article BRAMINS.

SHAW, in our old writers, a grove of trees, or a wood. It is mentioned 1 Inft. 4. *Blount.*

SHEAR *off*, in the fea language, the fame as to get away.

SHEARING (*Cycl.*)—The beft time for *fhearing* of fheep is about the middle, or the latter end of June, becaufe it is good for them to fweat in the wool before it is cut. They muft be very well wafhed before the *fhearing*, for this is a great addition to the price of the wool: after the wafhing, let them go three or four days in a clean dry ground. When they are cut, the fhearer muft be very careful not to wound their

their skins, because this gives occasion to the flies to teaze the poor creature in a terrible manner. Some *shear* their lambs, the first year especially, behind; but before the doing of this they ought to be carefully tagged, as it is called, that is, their tails and thighs behind should be well cleared of wool, that the dung may not hang there, which would else make them sore, and subject them to the flies, which would blow them, and make them full of maggots.

In Gloucestershire they house their sheep every night, and litter them with clean straw. Their dung makes this a very good manure for the land, and the wool of the sheep is rendered so much finer by it, that the farmers have a double advantage from the practice.

In Middlesex, and about London, they have Way-hill sheep: these come from Hampshire, Wiltshire, &c. and lamb very early, before Christmas. *Mortimer's* Husbandry.

SHEARING, in the sea language. See CHEST-*rope*.

SHEAT *of a plough*, a word used by our farmers to express a part of a plough, passing through the beam, and fastened to the share. The *sheat*, or, as it is sometimes called, the *fore-sheat*, (there being another timber behind it, called the *hinder-sheat*) should be seven inches wide, and is fastened to the beam by the retch, a piece of iron with two legs, and by a wedge driven with it, into the hole in the beam. The angle made by the *sheat*, with the beam of the plow, should be forty two, or forty three degrees. *Tull's* Husbandry. See the article PLOUGH.

SHEATS, in a ship, are ropes bent to the clews of the sails, serving in the lower sails to hale aft, or round-off the clew of the sail; but in top-sails they serve to hale home, as the word is, or to hale the clew of the sail close to the yard-arm.

If the main-sail-*sheats* are haled aft, it is in order to make a ship keep by a wind, but when the fore-*sheats* are haled aft, it is that the ship may fall off from the wind; and if she will not do it readily, they then hale the fore-sail, by the *sheat*, flat in, as near the ship's sides as they can; and this they call *flatting in the fore-sail*. When they say, *ease the sheat*, they mean veer it, or let it go out gently; but when the word is, *let fly the sheat*, they mean, let it go all at once, and run out as fast as it can; and then the sail will hang loose, and hold no wind. In a very great gale, or gust of wind, there is another rope bent to the clews of the main-sail and fore-sail, above the *sheat*-block, to succour and ease the *sheat*, and this they call a *false sheat*.

SHEATS, in a ship, also, are those planks under water which come along her run, and are closed into the stern-post; so also that part within board, in the run of the ship, is called the *stern-sheats*. The seamen say, when they would have the *sheats* of the main or fore-sail haled aft, *tally the sheats*.

False SHEAT, on board a ship, is a rope bent to the clews of the main-sail and fore-sail, above the *sheat*-block, to succour and ease the *sheat* in a violent gust of wind.

Overhale the SHEAT, in the sea language, a word of command to hale upon the standing part of the *sheat*.

SHEAT *anchor*, in a ship. See ANCHOR.

SHEATHING (*Cycl.*)—SHEATHING *of a ship*, is casing that part which is to be under water, with something to keep the worms from eating into her planks. It is usually done by laying tar and hair, mixed together, all over the old plank, and then nailing on thin new boards; but this hinders a ship's sailing, and therefore of late some have been *sheathed* with milled lead.

It is very well worth the trying what the new stone-pitch will do in this case; if it will defend from the worm, as perhaps it may, a ship might be paid with it cheaper than with the crown-pitch; and it will not crack nor scale off, as that will do, but keeps always soft and smooth. It has been found to continue on thirteen months, and to remain very black and soft all the time.

SHEDDING *of the hair*, in the manege. See CAST.

SHEEP, *ovis*, in zoology. See the article OVIS.

This is a kind of cattle that is kept at the least expence of any to the farmer, and will thrive upon almost any ground, and for this reason many prefer them before the larger cattle.

The best sort of *sheep* for fine wool, are those bred in Herefordshire and Worcestershire, but they are small, and black faced, and bear but a small quantity.

Warwick, Leicestershire, Buckingham, and Northamptonshire, breed a large-boned *sheep*, of the best shape, and deepest wool we have good. The marshes of Lincolnshire breed a very large kind of *sheep*, but their wool is not good, unless the breed be mended by bringing in *sheep* of other counties among them, which is a scheme of late very profitably followed there.

The northern counties in general breed *sheep* with long, but hairy wool, and Wales bears a small hardy kind of *sheep*, which has the best tasted flesh, but the worst wool of all.

The farmer should always buy his *sheep* from a worse land than his own, and they should be big-boned, and have a long greasy wool, curling close and well. These *sheep* always breed the finest wool, and are also the most approved of by the butcher for sale in the market.

For the choice of *sheep* to breed, the ram must be young, and his skin of the same colour with his wool, for the lambs will be of the same colour with his skin. He should have a large long body, a broad forehead, round, and well rising, large eyes, and strait and short nostrils. The polled *sheep*, that is those which have no horns, are found to be the best breeders. The ewe should have a broad back, a large bending neck, small, but short, clean and nimble legs; and a thick deep wool covering her all over. To know whether they be sound or not, the farmer should examine the wool, that none of it be wanting, and see that the gums be red, the teeth white and even, and the brisket skin red, the wool firm, the breath sweet, and the feet not hot. Two years old is the best time for beginning to breed, and their first lambs should not be kept too long, to weaken them by suckling, but be fold as soon as conveniently may be. They will breed advantageously, till they are seven years old.

The farmers have a method of knowing the age of a *sheep*, as a horse's is known by the mouth. When a *sheep* is one shear, as they express it, it has two broad teeth before; when it is two shear, it will have four; when three, six; and when four, eight: after this their mouths begin to break. The difference of land makes a very great difference in the *sheep*. The fat pastures breed strait, tall *sheep*, and the barren hills and downs breed square short ones; woods and mountains breed tall and slender *sheep*, but the best of all are those bred upon new-plowed land, and dry grounds. On the contrary, all wet and moist lands are bad for *sheep*, especially such as are subject to be overflowed, and to have sand and dirt left on them. The salt marshes are, however, an exception to this general rule, for their saltness makes amends for their moisture; any thing of salt, by reason of its drying quality, being of great advantage to *sheep*.

As to the time of putting the rams to the ewes, the farmer must consider at what time of the spring his grass will be fit to maintain them and their lambs, and whether he has turneps to do it till the grass comes; for very often both the ewes and lambs are destroyed by the want of food; or if this does not happen, if the lambs are only stunted in their growth by it, it is an accident that they never recover. The ewe goes twenty weeks with lamb, and according to this it is easy to calculate the proper time. The best time for them to yean is in April, unless the owner has very forward grass, or turneps, or the *sheep* are field-*sheep*, where you have not enclosures to keep them in, then it may be proper they should yean in January, that the lambs may be strong by Mayday, and be able to follow the dam over the fallows, and water furrows; but then the lambs, that come so early, must have a great deal of care taken of them, and so indeed should all other lambs at their first falling, else, while they are weak, the crows and magpies will peck their eyes out.

When *sheep* are turned into fields of wheat or rye to feed, it must not be too rank first, for if it be, it generally throws them into scowerings. Ewes that are big should be kept but bare, for it is very dangerous to them to be fat at the time of their bringing forth their young. They may be well fed indeed, like cows, a fortnight beforehand, to put them in heart. *Mortimer's* Husbandry, p. 243.

The feeding *sheep* with turneps is one great advantage to the farmers, from the crops they raise of them: they soon fatten upon them, but there is some difficulty in getting them to feed on them; the old ones always refuse them at first, and will sometimes fast three or four days, till almost famished, but the young lambs fall to at once.

The common way, in some places, of turning a flock of *sheep* at large into a field of turneps, is very disadvantageous, for they will thus destroy as many in a fortnight as would have kept them a whole winter. There are three other ways of feeding them on this food, all of their several advantages.

The first way is to divide the land by hurdles, and allow the *sheep* to come upon such a portion only at a time, as they can eat in one day, and so advance the hurdles farther into the ground daily, till all be eaten. This is infinitely better than the former random method, but they never eat them clean even this way, but leave the bottoms and outsides scooped in the ground; the people pull up these indeed with iron crooks, and lay them before the *sheep* again, but they are commonly so fouled with the creature's dung and urine, and with the dirt from their feet, that they do not care for them; they eat but little of them, and what they do, does not nourish them like the fresh roots.

The second way is by enclosing the *sheep* in hurdles, as in the former, but in this they pull up all the turneps they suppose the *sheep* can eat in one day, and daily remove the hurdles over the ground, whence they have pulled up the turneps: by this means there is no waste, and less expence, for a person may in two hours pull up all those turneps; the remaining shells of which would have employed three or four labourers a day to get up with their crooks out of the ground, trodden hard by the feet of the *sheep*; and the worst is, that as in the method of pulling up first, the turneps are eat up clean; in this way, by the hook, they are wasted, the

the *sheep* do not eat any great part of them, and when the ground comes to be tilled afterwards for a crop of corn, the fragments of the turneps are seen in such quantities on the surface, that half the crop at least seems to have been wasted.

The third manner is to pull up the turneps, and remove them in a cart or waggon to some other place, spreading them on a fresh place every day; by this method the *sheep* will eat them up clean, both root and leaves. The great advantage of this method, is, when there is a land not far off which wants dung more than that where the turneps grow, which perhaps is also too wet for the *sheep* in winter, and then the turneps will, by the too great moisture and dirt of the soil, sometimes spoil the *sheep*, and give them the rot. Yet such ground will often bring forth more, and larger turneps than dry land, and when they are carried off, and eaten by the *sheep* on plowed land in dry weather, and on green sward in wet weather, the *sheep* will succeed much the better; and the moist soil, where the turneps grow, not being trodden by the *sheep*, will be much fitter for a crop of corn, than if they had been fed with the turneps on it. The expence of hurdles, and the trouble of moving them, is saved in this case, and this will counterbalance at least the expence of pulling the turneps, and carrying them to the places where they are to be eaten. They must always be carried off for oxen. *Tull's* Horsehoeing Husbandry.

The use of salt preserves *sheep* from the rot. The animals must be made to take a small handful of it two or three times in a few days, without permitting them to drink any thing for some hours afterward. *Boyle's* Works abridged, Vol. 1. p. 109.

Folding of SHEEP. See the article FOLDING.

SHEEP's *dung*. This is one of the best manures we know. It succeeds better upon cold clayey lands, than any other dung whatever; but as it is not so conveniently to be collected as the dung of larger animals, it is commonly conveyed to the land, it is intended for, by folding the *sheep* upon it. The urine, as well as the dung, is thus given to the land, and is of very great advantage; but the farmer always should plow in this sort of manure as soon as he can, for the sun soon robs it of a great part of its virtue.

In Northamptonshire they begin to fold the *sheep* upon the lands that they would dung by them, after the month of July, and the drier the lands are, the later they fold them. In Flanders they make many thousand loads of manure annually from their *sheep*: they cover the bottom of the folds considerably deep with some light and spungy earth, and when this has received the dung and urine of the animals for seven or eight days, they remove it, and lay fresh in its place: the earth thus impregnated, becomes an excellent improvement to land, and they raise large crops by means of it, in places where very little could be expected without it. In England we have a contrivance like this, which is the covering the bottoms of the folds deep with sand, and changing it once in a week, or thereabouts: this is a kind of manure finely calculated for clayey lands, both the sand, and this peculiar kind of dung, being appropriated things for it. *Mortimer's* Husbandry.

SHEEP-*nose-worms*, in natural history, a species of fly-worm, found in the noses of *sheep*, goats, and stags, and produced there from the egg of a large two-winged fly.

The frontal sinuses above the nose in *sheep*, and other animals, are the places where these *worms* live, and attain their full growth. These sinuses are always full of a soft white matter, which furnishes these *worms* with a proper nourishment, and are sufficiently large for their habitation; and when they have here acquired their destined growth, and come to the state in which they are fit to undergo their changes for the fly-state, they leave their old habitation, and falling to the earth, bury themselves there; and when these are hatched into flies, the female, when she has been impregnated by the male, knows that the nose of a *sheep*, or other animal, is the only place for her to deposit her eggs, in order to their coming to good. *Reaumur's* Hist. Inf. Vol. 4. p. 552.

Mr. Vallisnieri, to whom the world owes so many discoveries in the insect class, is the first who has given any true account of the origin of these *worms*. Though their true history had been, till that time, unknown, the creatures themselves were very early discovered, and many ages since were esteemed great medicines in epilepsies.

It is very common to find only one *worm* in the head of the creature that has them, often two are found, and sometimes three, but very seldom any more than that. *Reaumur*, ibid. p. 554.

Redi has given a very imperfect figure of this creature, nor is that of Mr. Vallisnieri much better. The *worm* is of the first class, and has two brown hooks at the anterior part of its head, placed parallel, or nearly parallel to one another. It is composed of eleven rings, which together form a conic figure, something flatted, of which the head of the *worm* is the point. When the *worm* is young, it is very white, but has two brown spots placed over against each other, in the hinder part of its body, which are its two posterior stigmata. Each of these spots is parted into two by a concentric circle, which is sensible; as it is whitish, the rest of the spot being brown. It is plainly this very separation which gives passage to the air. When the creature pleases it shews these, but it can also draw them into a sort of purse in its posterior ring. The anus is just below, and is usually hid by the folds of the skin. The hooks are brown and strong; just above these are two little fleshy horns, and between them is placed the mouth. *Reaumur*, ibid. p. 555.

This *worm*, when at its full growth, is considerably large, and becomes brownish, or of a dirty white. Its belly, examined by the microscope, is seen furnished with a number of fine short prickles between the rings: the points of all these are turned backward, and one may even feel these prickles, in drawing the finger along the belly from the hinder part toward the head.

These *worms* are capable of moving themselves very swiftly; and it is doubtless owing to their motions in the head of the creature, and to the pain that the sensible membranes there must have from being wounded by the hooks and prickles of this creature, that *sheep* are often seen to grow outragious, and strike their heads against trees, and other hard bodies. Ibid. p. 556.

When these *worms* are taken out of the heads of *sheep*, if they are put upon the earth, they immediately bury themselves very deeply in it; and if not, yet at their full growth, or in a proper state for their changes, they die there: but if it be near the time that they would naturally have quitted their antient habitation, which may be known by their being changed from their fine white to a brownish colour, then they undergo all their proper changes under a shell, made by the hardening of their own skin. This shell is of the same shape with the animal itself, but is of a deep brown. Ibid. p. 557.

It takes some time for the creature to undergo its several changes, and that more or less, according to the season. Mr. Vallisnieri had one produced in the perfect fly-state, after forty days from the time of its first change. Mr. Reaumur found those, which formed their shell on the twenty fourth of April, not to produce the fly before the twenty seventh of June. Ibid. p. 558.

The creature, when ready to appear in the fly-state, has no great difficulty in the getting out of its case; the swelling and inflating its head, and throwing out its bladder, which is the practice of these creatures on this occasion, easily detaches a piece of the shell, originally loose, and gives the fly a sufficient passage.

The fly, produced from this worm, has all the time of its life a very lazy disposition, and does not like to make any use either of its legs or wings. Its head and corcelet together are about as long as its body, which is composed of five rings, streaked on the back; a pale yellow and brown are there disposed in irregular spots; the belly is of the same colours, but they are there more regularly disposed, for the brown here makes three lines, one in the middle, and one on each side, and all the intermediate spaces are yellow. The wings are nearly of the same length with the body, and are a little inclined in their position, so as to lie upon the body; they do not, however, cover it, but a naked space is left between them. The ailerons, or petty wings, which are found under each of the wings, are of a whitish colour, and perfectly cover the balancers, so that they are not to be seen without lifting up these. The upper part of the corcelet is full of small black prominences, which, when examined by the microscope, appear as so many corns of gunpowder. Its head is large, in proportion to the size of the body, and its reticular eyes are of a deep changeable green. These eyes take up less space in the head, than those of most other flies; they leave a considerable space between them, and in that are placed the three smaller, or glossy eyes, which are placed in form of a small triangle, and stand so near, as to touch one another. The rest of the upper part of the head is yellowish, and viewed by the microscope, appears cavernous like a spunge, or morel, and in the bottom of each of these small cavities is a little black prominence. There are two other hollows in the anterior part of the head, in which the antennæ are placed: these are of the battledoor form, but rather round than flat, and have each a large hair going from them. The under part of the head, which is rounder than the upper, is whitish, and very smooth; it has two sorts of bands directed downward, which are the elongations of the rims of the arches where the antennæ are lodged. The smoothness of the underpart of the head makes one see very distinctly these three little tubercles; the upper one brown, the under ones of a pale deadish yellow. The mouth of the fly seems to be placed between these, immediately under the upper tubercle. Ibid. p. 559, 560.

The fly will live two months, after it is first produced from the shell, but will take no nourishment of any kind; and possibly it may be of the same nature with the butterflies, which never take any food during the whole time of their living in that state. Ibid. p. 561.

SHEEP-*ſtealing*, is now made felony without benefit of clergy. See the article CATTLE.

The like penalty is enacted for killing *ſheep*, with an intent to ſteal the fat, or any part of the carcaſe, or for aſſiſting in any ſuch offence. Stat. 14 Geo. II. cap. 6. ſect. 1.

SHEERS, aboard a ſhip, a name the ſeamen give to two maſt's yards, or poles, ſet up and ſeized acroſs each other aloft, near the top. This pair of *ſheers*, as they call it, is placed below on the chain-wales of the ſhrouds, and laſhed faſt to the ſhip's ſide, to keep them ſteady aloft. Their uſe is to ſet in, or take out a maſt; for which end there is faſtened at the place where they croſs one another, a ſtrong double block with a ſtrap. They ſerve alſo to hoiſe in or out, of boats that have maſts, ſuch goods as are wanted to be taken in or out.

SHEER-*water*, in zoology, an Engliſh name for a bird common on our coaſts, and not known by any of the common authors, nor honoured with a Latin name. It is nearly of the ſize of a duck. Its head, which is large, neck and back, are of a browniſh black; its throat, breaſt and belly, white; its legs are red. Its three fore toes are connected by a membrane, but its hinder one is looſe. Its wings are very long, and when folded reach to the end of the tail. Its beak is ſtrong and ſharp, and is hooked at the end. It flies very ſwiftly along the ſurface of the water, whence it has its name. *Ray's* Ornitholog. p. 252.

SHEET, in the manege. See CAPARASON, *Cycl.*

SHEIK, in the Oriental cuſtoms, the perſon who has the care of the moſques in Egypt; his duty is the ſame as that of the imams at Conſtantinople. There are more or fewer of theſe to every moſque, according to its ſize or revenues. One of theſe is head over the reſt, and anſwers to a pariſh prieſt with us, and has under him, in large moſques, the readers, and people who cry out to go to prayers; but in ſmall moſques the *ſheik* is obliged to do all this himſelf. In ſuch it is their buſineſs to open the moſque, to cry to prayers, and to begin their ſhort devotions at the head of the congregation, who ſtand rank and file in great order, and make all their motions together. Every Friday the *ſheik* makes an harangue to his congregation. *Pocock's* Egypt. p. 171.

SHEIK-*bellet*, the name of an officer in the Oriental nations. In Egypt the *ſheik-bellet* is the head of a city, and is appointed by the paſha. The buſineſs of this officer is to take care that no innovations be made, which may be prejudicial to the port, and that they ſend no orders which may hurt the liberties of the people. But all his authority depends on his credit and intereſt, not his office: for the government of Egypt is of ſuch a kind, that often the people of the leaſt power by their poſts have the greateſt influence; and a caia of the janizaries, or Arabs, and ſometimes one of their meaneſt officers, an oda-baſha, finds means, by his parts and abilities, to govern all things. *Pocock's* Egypt, p. 163.

SHELF, (*Cycl.*) a term uſed by the miners, in many parts of England, to expreſs a diſtinction of the inner ſtructure of the earth, ſo little known to philoſophers, that they have no word to expreſs it by. Theſe workmen ſometimes alſo expreſs it by the term *faſt ground*, or *faſt country*. What they mean by this, is, that part of the earth, which they find lying even, and in an orderly manner, and evidently having retained its primitive form and ſituation, unmoved by the waters of the general deluge, while the circumjacent, and upper ſtrata, have plainly been removed, and toſſed about.

It is evident to reaſon, that there muſt have been a very violent concuſſion of the ſuperficial part of the earth, in the time of its being covered by the waters of the deluge; and experience as much evinces this as reaſon. Before this concuſſion it appears probable, that the uppermoſt ſurface of mineral veins, or loads, did in moſt places lie even with the then ſurface of the earth. The remains of this ſurface, found at different depths in digging, the miners expreſs by the word *ſhelf*.

In this concuſſion of the waters covering the whole earth, its natural ſurface, together with the uppermoſt ſurface of thoſe mineral veins, were then in many places looſened, and torn off; and the earth, and with it the mineral nodules, called *ſhoad-ſtones*, were carried down with the deſcending waters from hills into the adjacent valleys, and ſometimes into the ſtreams of rivers, by which they were waſhed to yet greater diſtances from their original place. On this depends the method of training mines. Philoſoph. Tranſ. N° 69. See the article TRAINING.

SHELL (*Cycl.*)—SHELL-*fiſh*, *conchylia*. The world has for a long time wanted a regular method of claſſing of *ſhell-fiſh*, which a late author of the French nation has attempted, upon a new and very valuable plan. In this he throws aſide the vulgar diſtinction of *ſhells*, into the ſea, freſh water, and land kinds, and very judiciouſly arranges all under the ſame claſs, which have the ſame general characters.

The *ſhells* are all naturally to be arranged under three principal claſſes; theſe will contain all the ſpecies, and are afterwards to be divided into a number of families, or genera, and under theſe the ſeveral ſpecies regularly recounted; and at the end of each deſcription, the varieties may be added. The firſt general claſs of *ſhells* contains thoſe which are found all of one piece, or have only one *ſhell*, not a pair. Theſe have been called by the Greeks *monothyræ*, and by the Latin authors *univalvia*, univalves.

The ſecond general claſs contains thoſe *ſhells* which are of two pieces, called *bivalves*, ſuch as oiſters, cockles, and the like. See Tab. of Shells, paſſim.

The third claſs contains thoſe which are compoſed of more than two pieces. Theſe are called *multivalves*; and of this kind are the pholas and balanus.

This method takes in the freſh-water-*ſhells*, as well as thoſe of the ſea; and as thoſe hitherto known are all of one or other of the firſt claſſes, their ſeveral ſpecies will be compriſed among, or after the ſea *ſhells* of each of thoſe claſſes.

The land-*ſhells* are of two kinds, the recent and the foſſile; the firſt kind, as far as hitherto known, are all univalves, and the latter are of all the three claſſes.

As each of theſe general claſſes contains a very great number of ſpecies, it may ſeem difficult to enter on this ſtudy, from the multiplicity of the bodies; but method renders all this eaſy, and it is no way difficult, in the following manner, to find of what claſs, what family, and what genus, any given *ſhell* is, from a bare inſpection.

The *ſhell* is firſt to be examined, to ſee whether it is compoſed of one, two, or more pieces. If it is found to conſiſt only of one piece, it is known thence to belong to the claſs of univalves; if of two, to the bivalves; and if of more, to the multivalves. When it is thus referred to its proper claſs, its family and genus will be found by farther examination of its general form, and the ſhape of its mouth, or aperture.

As ſoon as a given *ſhell* is found to be univalve, the five genera of that claſs are to be uſed in compariſon with it, in order to ſee to which of them it belongs. If it has no turn or twiſt, but forms one ſimple figure, approaching to a cone, and pointed at the top in the manner of the common limpet, or patella, it is known to be of the family of the *patellæ*; the character of which is to have only one valve, and that fixed in its natural ſtate to a ſtone, or other hard body, and of a flatted ſhape, though elevated into a ſort of point in the middle.

If the *ſhell* be not conic, but extremely flat, and ſomewhat of the ſhape of a man's ear, it is of the ſecond family of the *aures marinæ*, diſtinguiſhed by the epithet *planæ*, flat or plane. If it forms a tube or pipe, it is of the nature of the common *tubuli marini*, and is of that family. If, on the other hand, it reſemble a ſort of veſſel or boat, it is of the *nautilus* claſs, and belongs to the *naviculæ*.

Theſe are the diſtinctions, if it be plain, and without turnings; but if it have ſeveral twiſts, or wreaths, its aperture, commonly called the *mouth*, is to be examined, for this forms, in this caſe, the generical character. If the mouth be exactly round, the *ſhell* is of that family of the *cochleæ*, or ſnails, called by the antients *lunares*. If it be of a ſemicircular figure, it is of that family of ſnails called *ſemilunares*; under which family are compriſed the *neritæ*, as one genus.

If the *ſhell* approaches to a conic figure, and grows larger at the baſe, and has a flatted or oval mouth, it is of a ſeventh order of *cochleæ*, or ſnails diſtinguiſhed by the title *cochleæ ore depreſſo*.

If the *ſhell* have the exterior figure of a trumpet, and has a large tail, it belongs to the family of the *buccina*; of which, however, it is to be remarked, that there are ſome ſpecies which have not long tails: in this diſtinction we alſo have recourſe to the mouth, which is larger than that of the murex, leſs long, and its lower part is formed into a crooked beak. Theſe are the eſſential characters which diſtinguiſh this family of *ſhells*; a family, concerning which there is great confuſion among authors.

If the baſe of the *ſhell* be ſmall, and the whole diminiſh gradually in ſize from this to the end, which is pointed, then the *ſhell* is of the family of the *turbines*. If a *ſhell* form a cone, or cornet, there is no occaſion to look at the mouth, this figure alone determines it to be a *voluta*; and if one of its extremities is nearly as large as the other, it is then a rhombus. This genus of *ſhells* has been called *cylindri* by the Latins, and *rouleaux* by the French. When this rhombus, or cylinder, has a pointed baſe, frequently ornamented alſo with ſeveral ſmall eminences; and when its middle is large, and is in the ſame manner ſurrounded with tubercles, and its head is elongated by ſeveral turns, and its mouth of an oblong figure, and furniſhed with teeth; and when, as is often the caſe, there is an excreſcence of the plate that covers the mouth, called by authors an *ala*, or wing, this *ſhell* muſt be placed among the family of the *murex*, or, as the French call it, the *rocher*.

The *purpura* is diſtinctly not a ſynonymous term with the precedent, but expreſſes ſuch a *ſhell*, which, inſtead of being furniſhed with points, is cut and curled from top to bottom, in the manner of the leaves of our curled cabbages, or of the endive raiſed for ſallads. The body in this genus is alſo more compact, and more detached from the other parts,

parts, than in the other genera of this kind, and the mouth is usually small and round, and the tail long and crooked, furnished with long points, and hollowed within in form of a pipe.

If the *shell* is round, it belongs to that family of *shell-fish* called, from their figure, *globosæ*, and in French *tonneaux*. It is to be observed, however, that all *shells*, which appear at first sight of a rounded figure, are not to be placed at once in this family; for the helmet *shell*, for instance, which appears roundish, though somewhat triangular, is not to be supposed of this family, but is a murex. The summit of the head, and the little tuberosities, on this occasion, give the essential character, and point out its proper genus: for the *shells* of the globose kind are truly of a spherical figure; they are inflated in the middle, have no tubercles on the head, and have a large and hollowed mouth, but no teeth.

The last family of the univalves is the porcelain, or *concha veneris*, a genus so well known, that it needs no particular description. Sometimes at the summit of this *shell* there is a small spiral, and sometimes its opening is not exactly in the middle. Some are light and thin, others very thick and hard: but these are only varieties of the same genus, the proper family of the *shell* being always thus determined by the mouth.

Bivalve SHELLS. The former are all the genera of the *shells* composed of one piece, and thence called *univalves*: and as any given *shell* may, by the characters given of each, be easily referred to that to which it belongs, so, in regard to the *bivalves*, the task is not more arduous, when entered on upon the same principles; and it is the easier in this respect, that the families of this class are much less numerous than those of the other, these being only six. The first genus, or family of the *bivalves*, is that of the *oister*, *ostreæ*. The variety in this one genus is almost infinite, and is extremely agreeable. Some are echinated so, as to represent the echini; others have excrescences of parts in undulatory, or jagged forms, representing the ears of animals, or the comb of a cock; and others form themselves into very remarkable figures, by adhering and growing to trees, stones, corals, and other substances, either naturally growing in the sea, or such as have accidentally fallen into it. Sometimes also, the upper *shell* in an oister is smaller and flatter than the under one. These, however, are all trifling varieties, and the *shells* are still of the oister kind.

When the *bivalve shells*, under examination, differs from the oister kind, in being more elevated in the middle, and equally convex, or nearly so, in both *shells*, then it belongs to the family under the name of *chamæ*. These differ also from oisters, in that they are more smooth on the surface, and they often do not close so evenly and regularly at the mouth, whence some have called them *conchylia ore patulo, et hianti*.

The third family is that of the *muscles*. These are all of the general shape of the common muscle, and are thence easily known. It is to be observed, however, that some of them are equal at both ends; these are called *tellinæ*: and some others are extremely long at one end, and broad and short at the other; these are called *pinnæ marinæ*.

The fourth genus, or family, is the cordiform kind, called in French *cœurs*. The essential character of this family is, that the *shells* are of a roundish elevated figure, and that they have no ears, as the pectens have, and they always represent the figure of a heart, in whatever view they are taken; tho' this is sometimes of a triangular figure. Most of the species of this family, as well as of the following one of the pectens, are striated.

The fifth family of the *bivalves*, is that of the *pectens*, or scallop-*shells*. Among these, some have two ears at the head of the *shell*; others have only one ear; and others have none at all. Some species are deeply furrowed, and others are full of small protuberances. The general character of the pectens is to have the upper *shell* plain, and the under one somewhat hollow; and the ears are also a very obvious character in those that have them.

The sixth, and last family of the *bivalves*, is the *solen*, or razor-fish, called by the French *manche de couteau*. These are very easily known by their figure, which resembles that of a knife-haft, and therefore need no other mark of distinction.

Multivalve SHELLS. These are not less easily distinguished, than the other two general classes, into their separate families. Of these also there are six families. The first is that of the *echini marini*, called in English *sea-eggs*, and by the French *oursins*, *boutons*, and *herissons de mer*. These carry a very obvious distinction, in their being covered with spines, or prickles; and if we meet with them in a state, when these are fallen off, they are still easily known by the marks of their insertion. This, and their general figure, which is alike in all, and in all unlike to all other species, is such a distinction, as cannot suffer them to be mistaken.

The second family of these, is that of the *vermiculi marini*, particularly charactered in the species called the *sea-organ*. These are usually of a beautiful red colour, and are of a very elegant structure. They generally are found in very large clusters, and are easily distinguished from all other genera.

The third family of the *multivalves* consists of the *balani marini*, called by the French *glands de mer*. These are all so like one another, that they are easily known from all the other genera, by their all resembling the common balanus, a *shell* too well known to need description.

The fourth family is that of the *pollicipedes*, or, as the French call them, the *pousspieds*. These are so easily known by their perfect resemblance to one another, that there needs no other character than referring to their figure in the plate of *shells*.

The fifth family of the *multivalves* is that of the *conchæ anatiferæ*. These were once supposed to produce a bird of the goose kind; and these are all so like to one another, that the referring to the figure of the common species, in the general plate, will shew the characters of all the species.

Finally, the sixth genus of the *multivalves* is that of the *pholas*. These *shells* are easily distinguished by their figure, which is usually oblong, and their colour, which is simply white in all the species. These *shells* are often found enclosed in stone in the sea, and some of them are composed of five valves.

By these characters it will be easy for an utter stranger to these studies, to refer any *shell*, he occasionally meets with, to its proper class and family. When this is done, it will be easy to observe the lesser differences, which, though not sufficient to constitute different families or genera, yet very well distinguish different species of the same genus, or family; and by comparing these with the names of the several species, to be found enumerated under the head treated of, in the name of that genus or family to which the *shell* is found to belong, it will be soon discerned whether, and which of these species it is of, or whether agreeing with none of those names, it is a new species. In order to enquire into these specific differences, it is necessary attentively to consider the exterior parts of the *shell*, its figure, its mouth, its volutions, its alæ, and its smoothness or roughness, and its two extremities, the end of the clavicle, and the mouth. After the exterior parts have been thus examined, the interior ones must be taken into consideration, as the length and hollow of the mouth, and whether it be furnished with teeth, or with ridges; and whether it have a chamber, or a tongue within.

In regard to *bivalves*, when the species are to be distinguished, we must observe whether the two valves are equal, or unequal in shape and size; whether one is, or is not more elevated than the other; and whether these valves are smooth, or are covered with wrinkles and tuberosities, or points; whether they have, or have not ears; and whether their striæ are charged with points, or tubercles, or are plain and smooth on the surface; and finally, whether they are longitudinal, or transverse, and whether the ends of the *shells* are even, or are terminated by a point, or beak.

The insides are next to be observed, to find whether the *shells* naturally close evenly and exactly, or whether they remain naturally open; and whether the fish is affixed to them by a single ligament, as is the common case, or by six regular muscles, as the sea-muscle does.

The mouth of a *shell* generally distinguishes it from others, but there are some species in which recourse must be had to the other external parts of the *shell*: and we are not to be puzzled, on finding in the same family some small differences in the figure of the mouth, as its being longer in one species, and wider in another; the one species having a tail, and the other not; the one having a summit elevated very high, the other flatted at the top; or, lastly, the one being smooth, and the other covered with tubercles, do not prevent both from being of the same family, when the general characters are the same. These then only distinguish the species and genera of the same family, which are to be placed one after another in the descriptions of it.

The species are distinguished, when the generical characters being the same, one *shell* is umbilicated, another is not; one smooth, another rough, and so on. The varieties of the several *shells*, which are very numerous, and have by many been taken for real species, are distinguished by less essential differences; such as the size, the length, and the thickness of the *shell*, the difference of the colours, and the depth, or slightness of the furrows.

It may not be amiss to explain all this in some one family of *shells*, in which there are many different genera, species, and varieties. When the buccinum, for example, has a long or a short mouth; when its clavicle, or pyramid, is long, or is flatted; or when its beak is strait, or crooked; these are the marks of genera, being very great and essential characters, and each of them belonging in common to a great number of *shells*, which are to be called species, and are to be distinguished from one another only by some epithet, expressive of their slighter differences. Thus if the surface is smooth, it is called *buccinum læve*; if rough, *buccinum tuberosum*; if it imitate a spindle, it is called *fusus*; if it be of the figure of a tower, it is called *turris*; and if of a tiara, it is called *mitra papalis*. The varieties are after this distinguished by their proper epithets; the white, red, or yellow, are so called, and the large and small distinguished by those words

lowing the trace of the wreath. The neck of the growing snail is the part which principally forms the *shell*; this is always naked, and is always making itself a covering, which, while the neck grows beyond it, serves for the next part. Now if we suppose this neck to be yellow, with one black spot in a particular part; or rather, that it all over exsudates a yellow liquor, except in some one spot, where it exsudates a black one; then it necessarily follows, that as the growth of the animal is performed in a spiral line, and the *shell* made accordingly, while the yellow matter makes a wreath of yellow *shell* surrounding the former, the black part must also be drawn in the same spiral form, as we see a spiral line of that colour in the wreath. And accordingly, if there be more points than one of this kind, then there must be more rays or lines also in the *shell*; and if these points are of different colours, then the rays formed by them will be also of different colours; neither are these black points, or spots, to be treated as a mere conjecture; they in reality ever appear upon the animal; and if a growing snail be nicely inspected, they are always found placed just even with the black lines, or rays, which are carrying round the *shell*.

The part of the body of the snail which immediately follows the neck, and fills up that part of the *shell* it has just formed, discharges neither a yellow nor a black liquor, but only a thin aqueous whitish humour; this condensing on the inside of the new formed *shell* coats it over, and forms its inner covering, which therefore is always whitish, and has no varieties of colour.

It will be very easy for every naturalist to extend what is here related of the common garden snail to all the other animals which are covered in the same manner with *shells*; and the differences of colour in the matter transpired through the neck of the growing animal, with the different number and disposition of the variegating points or dots on it, may give sufficient room to account for all the beautiful variety of colours, and all the variegations in the most elegant sea-*shells*.

The other varieties of them may also be accounted for upon the same principle; thus, suppose the growing fish of one kind has a number of eminencies on its body, there cannot fail to be prominences of the same kind in the *shell* that is formed by the regular transpiration of its juices; and these will go on regularly, enlarging to the end of the *shell*, because the prominences which form them will grow larger in the animal as it grows. If there be any certain season of the year when the *shell* ceases to grow, that is when the animal ceases to enlarge its body, suppose this to be the summer or the winter, or whatever particular season; in this case, the traces of the different times of the creature's beginning to grow again, will not fail to be marked upon the *shell*; and the age of the *shell* might, if these times were known, be perhaps, in many cases, as well determined by these several junctions of new to the old matter, as trees are known by their annual concentric circles. Thus we see, that these tender animals are themselves the architects of these their elegant habitations, which are so beautifully regular, merely because they grow as it were with the body of that architect, whose different age and state of life, if perfectly understood, they would be found elegantly to denote. Mem. Acad. Par. 1709.

The durable hardness and excellent polish of many of the *shells* of sea-fishes, and that even in the thinnest and tenderest kinds, is a thing very amazing. In the ruins of the abbey of St. Edmundsbury, which is built of a kind of stone composed of grit or sand, interspersed with an infinite variety of very minute *shells*, principally of the small smooth cockle-kind, Mr. Collinson observed, that the stone having suffered greatly by the injuries of the air, the grit or sand of which it was composed had disunited and mouldered away, while the smallest of these *shells* stood the same injurious accidents unaltered, and were found standing forth in the utmost perfection, and with all their beautiful natural polish; yet these are as thin and tender a *shell* as almost any of the same size that we know of.

It is possible, indeed, that these *shells* might have been altered in their nature, by the insinuation of stony matter into their pores, as is a common case in *shells* lodged in stone; but those, here mentioned, did not seem to have undergone any such alteration; and it is very certain, that many of the like thin and tender *shells* are found preserved through a long series of ages, in places where they have been in the way of no such alterations from the insinuation of stony matter into their pores, and out of which they are taken fair and beautiful, and with all their natural polish, though not at all hardened in the time. Of this kind are the *shells* of the tender buccinums, and other thin kinds, found buried in earth, in the strata of marl, clay, or loam, and even in chalk.

As hard as these *shells* naturally are, they do not, however, preserve the fish, which inhabit them, from becoming the food of others, which seem to have no organs with which to break them. It is common to see the soal-fish with its belly prominent and hard, as if well filled with spawn, and yet when opened to find no spawn at all; but the prominence and hardness is occasioned by the stomach and guts being filled with *shell*-fish, which the creature had swallowed whole, as food, without having any power of breaking or destroying them. A small species of pectunculus, or cockle, is the fish that the soal usually feeds upon; and when the guts are taken out of this fish, they often resemble so many strings of necklaces, from the continued series of these *shells* which appear prominent in them. When these *shells* are taken out, many of them are usually found in part dissolved, and many entire and unaltered.

Shell-fish are well known to be the food of some other fishes of the larger kinds, particularly the sea-porcupine, and a kind of the wray-fish, are known principally to feed upon them; but these fish are provided by nature, with a suitable apparatus fitted for the grinding, or reducing them into a state more proper for digestion; their jaws being furnished with bony substances, extending to the palate and under part of the mouth, which are capable of reducing much stronger *shells* than these into an absolute pulp. The soal-fish has no apparatus of this kind, and neither its jaws nor stomach are furnished with any thing capable of wearing them to pieces by attrition; but what appears to be the case, is, that nature has furnished this creature with a menstruum in the body capable of digesting them. Phil. Trans. N° 473. p. 39.

The crab, like the lobster, &c. casts its *shell* once every year. Against this extraordinary event, the creature always chooses a close and well secured retreat in the cavities of rocks, or under great stones; there they creep in, and wait till all the parts are by degrees disengaged, which is effected by withdrawing their legs from their old *shells*, and leaving them and the upper part of their body *shell* behind. In this naked state they make a very strange appearance, being a mere ill-shapen lump of a fleshy matter, covered with a sort of jelly; this by degrees hardens into a *shell*, a degree larger than the old one cast off. Phil. Trans. N° 478. Sect. 14.

Polishing of SHELLS. See the article POLISHING.

Fossile SHELLS. The number and variety of sea-*shells* which are found far from seas buried at great depths in the earth, and often immersed in the hardest stones, is an object of great wonder.

Of these some are found remaining almost entirely in their native state, but others are variously altered by being impregnated with particles of stone, and of other fossiles; in the place of others there is found mere stone, or spar, or some other native mineral body, expressing all their lineaments in the greatest nicety, as having been formed wholly from them, the *shell* having been first deposited in some solid matrix, and thence dissolved by very slow degrees, and this matter left in its place, on the cavities of stone and other solid substances, out of which *shells* had been dissolved and washed away, being afterwards filled up less slowly with these different substances, whether spar or whatever else: these substances, so filling the cavities, can necessarily be of no other form than that of the *shell*, to the absence of which the cavity was owing, though all the nicer lineaments may not be so exactly expressed. Beside these, we have also in many places masses of stone formed within various *shells*; and these having been received into the cavities of the *shells* while they were perfectly fluid, and having therefore nicely filled all their cavities, must retain the perfect figures of the internal part of the *shell*, when the *shell* itself should be worn away, or perished from their outside. The various species we find of these are in many genera, as numerous as the known recent ones; and as we have in our own island not only the *shells* of our own shores, but those of many other very distant ones, so we have also many species, and those in great numbers, which are in their recent state, the inhabitants of other yet unknown or unsearched seas and shores. The cockles, muscles, oisters, and the other common bivalves of our own seas are very abundant: but we have also an amazing number of the nautilus kind, particularly of the nautilus græcorum, which though a *shell* not found living in our own, or any neighbouring seas, yet is found buried in all our clay-pits about London and elsewhere; and the most frequent of all fossile *shells*, in some of our counties, are the conchæ anomiæ, which yet we know not of in any part of the world in their recent state. Of this sort also are the cornua ammonis and the gryphitæ, with several of the echinitæ and others.

The exact similitude of the known *shells* recent and fossile in their several kinds, will by no means suffer us to believe, that these, though not yet known to us in their living state, are as some have idly thought, a sort of lusus naturæ. It is certain, that of the many known shores, very few, not even those of our own island, have been yet carefully searched for the *shell*-fish that inhabit them; and as we see in the nautilus græcorum an instance of *shells* being brought from very distant parts of the world to be buried here, we cannot wonder that yet unknown shores, or the unknown bottoms of deep seas, should have furnished us with many unknown *shell*-fish, which may have been brought with the rest; whether that were at the time of the general deluge, or the effect of any other catastrophe of a like kind, or by whatever other means, to be left in the yet unhardened matter of our stony and clayey strata. *Hill's* Hist. of Foss. p. 616.

quent there. Beſide theſe, and many other *ſhells*, there are found on this coaſt all the ſpecies of nautili, many of which are very beautiful.

The Canary iſles are found to abound with a vaſt variety of the murexes, and ſome other good ſhells; and we have, from Madeira great variety of the echini marini, or ſea-eggs, different from thoſe of the European ſeas. Several ſpecies of muſcles are alſo common there, and the auris marina is no where more abundant.

The Red Sea is beyond all other parts of the world abundant in *ſhells*, ſcarce any kind is wanting there; but what we principally have from thence are the purpuræ, porcelains, and echini marini.

The Mediterranean and northern Ocean contain a great variety of *ſhells*, and many of very remarkable elegance and beauty; they are upon the whole, however, greatly inferior to thoſe of the Eaſt-Indies. The Mediterranean abounds greatly more in *ſhells* than the Ocean. The gulf of Tarentum affords great variety of purpuræ, of porcelains, nautili, and elegant oiſters; the coaſts of Naples and Sardinia afford alſo the ſame, and with them a vaſt number of the ſolens of all the known ſpecies. The iſland of Sicily is famous for a very elegant kind of oiſter which is white all over; pinnæ marinæ and porcelains are alſo found in great plenty there with tellinæ and chamæ of many ſpecies, and a great variety of other beautiful *ſhells*. Corſica is famous, beyond all other places, for vaſt quantities of the pinnæ marinæ, and many other very beautiful *ſhells* are found there. *Liſter*, Hiſt. Conchyl.

About Syracuſe are found the gondola-*ſhell*, the alated murex, and a great variety of elegant ſnails, with ſome of the dolia and neritæ.

The Adriatic ſea or gulf of Venice is leſs furniſhed with *ſhells* than almoſt any of the ſeas thereabout. Muſcles and oiſters, of ſeveral ſpecies, are however found there, and ſome of the cordiformes or heart-*ſhells*; there are alſo ſome tellinæ. About Ancona there are found vaſt numbers of the pholades buried in ſtone, and the aures marinæ are particularly frequent about Puzzoli. *Bonani* Recreat. Ment. et Ocul.

The ports of Marſeilles, Toulon, and Antibes, are full of pinnæ marinæ, muſcles, tellinæ and chamæ. The coaſts of Bretagne afford great numbers of the conchæ anatiferæ and pouſſepieds, they are found on old rotten boards, on ſea-plants, and among cluſters of ſpunges. The other ports of France, as Rochelle, Dunkirk, Breſt, St. Malos, and others, furniſh oiſters, excellent for the table, but of the common kind, and of no beauty in their *ſhells*; great numbers of muſcles are alſo found there; and the common tellinæ, the onion-peel-oiſters, the ſolens and conchæ anatiferæ are alſo frequent there. At Granville, in Lower Normandy, there are found very beautiful pectens, and ſome of the cordiforms, or heart-*ſhells*. Our own Engliſh coaſts are not the leaſt fruitful in *ſhells*, though they do not produce ſuch elegantly painted ones as the Indies.

About Plymouth are found oiſters, muſcles, and ſolens in great abundance; and there, and on moſt of our other ſhores are numbers of the aures marinæ and dentalia, with pectens, which are very excellent food; and many elegant ſpecies of the chamæ and tellinæ are fiſhed up in the ſea, about Scarborough, and other places.

Ireland affords us great numbers of muſcles, and ſome very elegant ſcallop-*ſhells* in great abundance, and the pholades are frequent on moſt of our ſhores. We have alſo great variety of the buccina and cochleæ, ſome volutæ, and on the Guernſey coaſt a peculiarly beautiful ſnail, called thence the Guernſey-ſnail.

The coaſts of Spain and Portugal afford much the ſame ſpecies of *ſhells* with the Eaſt-Indies, but they are of much fainter colours, and greatly inferior in beauty. Hiſt. Nat. Eclairc. p. 172.

There are according to Tavernier and others ſome rivers in Bavaria, in which there are found pearls of a fine water. About Cadiz there are found very large pinnæ marinæ and ſome fine buccina. The iſles of Majorca and Minorca afford a great variety of extremely elegant *ſhells*. The pinnæ marinæ are alſo very numerous there, and their ſilk is wrought into gloves, ſtockings, and other things. The Baltic affords a great many beautiful ſpecies, but particularly an orange-coloured pecten, or ſcallop-*ſhell*, which is not found in any other part of the world.

The freſh-water-*ſhells* are found much more frequently, and in much greater plenty than the ſea-kinds. There is ſcarce a pond, a ditch, or a river of freſh water, in any part of the world, in which there are not found vaſt numbers of theſe *ſhells* with the fiſh living in them. All theſe *ſhells* are ſmall, and they are of very little beauty, being uſually of a plain greyiſh or browniſh colour. Our ditches afford us chamæ, buccina, neritæ, and ſome patellæ; but the Nile, and ſome other rivers, furniſhed the antients with a ſpecies of tellina, which was large and eatable, and ſo much ſuperior to the common ſea-tellina in flavour, that it is commonly known by the name of *tellina regia* the royal tellina. We have a ſmall ſpecies of buccinum common in our freſh waters, which is very elegant, and always has its operculum in the manner of the larger buccina; a ſmall kind of muſcle is alſo very common, which is ſo extremely thin and tender, that it can hardly be handled without breaking to pieces. The large freſh-water-muſcle, commonly called in England the *horſe-muſcle*, is too well known to need a deſcription, and the ſize of this, gives it a difference from all other freſh-water-*ſhells*.

Formation of Shells. The world, in general, has been much more inquiſitive, into the nature of the colours, and marks of the great variety of *ſhell*-fiſh, than what might appear much more worthy of enquiry, the manner of their production. It has been generally ſaid, that theſe *ſhells*, and thoſe of crabs and lobſters, which are of the cruſtaceous kind, were a ſort of bones, all of which in theſe creatures are placed by nature on the outſide of the body.

It has been ſuppoſed that both the *ſhell* and the body of the animal are produced from the ſame egg, and that the one developes and enlarges as the other does. But this, though a ſpecious reaſoning, does not ſeem to be the true ſtate of the caſe. On the contrary, it ſeems, as if the animal alone is produced from the egg, or contained in it, and that the production of the *ſhell* is a future piece of workmanſhip.

Mr. Reaumur is the firſt author who has publiſhed an account of the true production of *ſhells*, and has been at vaſt pains to make the neceſſary obſervations for this purpoſe. He obſerved, that the *ſhell* of the common garden-ſnail was plainly made of a viſcous matter, which tranſpired from the body of the creature in a liquid form, and hardened by degrees on contact with the air.

It is very well known that all animals continually perſpire, and are ſurrounded with a ſort of atmoſphere of their own, which is of the figure of their body; and all that is ſingular in the perſpiration of ſnails, is, that this atmoſphere of theirs hardens about them, till it forms a ſort of ſtony caſe, which being moulded upon their body muſt be of the ſame ſhape; while that of other animals, in general, diſſipates itſelf, and is loſt among the ambient air; and this difference plainly ariſes wholly from the nature of the matter perſpired, which in the ſnail is of a viſcous, and as it were a ſtony nature. It is evident, that this *ſhell* therefore is not at all of the nature of the bones of animals, being neither formed as they are, nor yet as any other parts of an animal body, but merely by an appoſition of particles: ſo that we have here an inſtance of a part of an animal body, which borrows its manner of formation from the ſtones, and other parts of the foſſile world. The head of the ſnail is always at the mouth or opening of the *ſhell*, and its tail at the other extremity, or as we uſually expreſs it, at the top of the *ſhell*; and the body of the ſnail from whatever cauſe, naturally turning itſelf into a ſpiral, gives origin to the volutæ of the *ſhell*.

When the ſnail is juſt hatched naked from the egg, and is in its utmoſt degree of ſmallneſs, it does not ceaſe to tranſpire, and immediately there is formed a *ſhell*, ſuited to its preſent ſmall ſtate, and exactly fitting every part of its body, which is yet too tender to twiſt itſelf into a ſpiral, ſo that this *ſhell* is only the center of that ſpiral, which is afterwards to be formed on that center, with a little part of the ſpiral proceeding from it. The animal after this grows, and if it now ceaſed to perſpire, it muſt be a neceſſary conſequence that the future part of the body muſt be naked. This, however, is not the caſe: it continues to perſpire, and every part of the body, as it is formed, becomes covered with the ſame ſhelly cruſt made by the hardning of that newly perſpired matter, as it comes in contact with the air. The body of the ſnail, in growing, turns itſelf round the firſt point, and afterwards round that again, ſo there is ſpiral upon ſpiral formed, and at the ſame time the *ſhell* is formed in the ſame ſhape to cover them. The other turns of the *ſhell* are afterwards formed juſt in the ſame manner, and theſe in the garden-ſnail ſometimes run as far as to the number four and an half.

It is a neceſſary conſequence of this manner of formation of theſe *ſhells*, that the firſt circles of a young ſnail, which has not yet above two of them, are of juſt the ſame ſize with the two firſt turns of a grown ſnail, which has four in the whole; for whatever part of the *ſhell* has been once formed, becomes ſubject to no increaſe in ſize afterwards in itſelf, but all the addition to it is made by the continual joining on of more new formed *ſhell* to its extreme edges. There is, however, an addition of matter to the inſides of theſe, to give them a greater ſtrength afterwards; for it may always be obſerved, that though theſe firſt turns, or ſpiral wreathes, in a young ſnail, are of the ſame ſize with thoſe in a more grown one, yet they are thicker afterwards by much than they are at firſt. The new grown part of the animal, which would otherwiſe have been naked, thus forms itſelf a covering by its perſpiration; to which the already covered part adds thickneſs and ſtrength.

In the common ſmaller and more beautiful garden-ſnails, the ground colour of the *ſhell* is uſually yellowiſh, whitiſh, or reddiſh, and is variegated with rays or lines of black, following

ſomewhat toward a triangular figure, and are free from any long ſpines. See MUREX.

Leopard-SHELL, in natural hiſtory, the Engliſh name of the pardus, a kind of voluta; ſo called, from its ſpots reſembling thoſe of a leopard. There are three kinds of this, one ſpotted with black, another with yellow, and another with red.

Leveret-SHELL, in natural hiſtory, a name given by many to a ſpecies of porcelain, reſembling a young hair in colour. See the article PORCELLANA.

Lightning-SHELL, in natural hiſtory, a name given by ſome authors to a ſpecies of murex with variegations on its body, reſembling the pictures we commonly ſee of flaſhes of lightning. See the article MUREX.

Map-SHELL, in natural hiſtory, the name given by ſome to a peculiar ſpecies of porcelain-*ſhell*, the figures on which repreſent the lines on a map. See PORCELLANA.

Noah's ark-SHELL. See the article NOAH.

Oiſter-SHELL. See the article OISTER.

Old wife-SHELL, the name given by ſome to that ſpecies of chama, which the French alſo have called *vielle ridée*. See the article VIELLE *ridée*.

Onion-SHELL. See the article OSTREA.

Pipe-SHELL, in the materia medica. See ENTALIUM.

Saddle-SHELL, in natural hiſtory, the name of a ſpecies of oiſter, which in ſome degree repreſents a ſaddle in its ſhape. See the article OSTREA.

St. James's SHELL, in natural hiſtory, a name given by writers on *ſhells* to a very beautiful ſpecies of variegated pecten. See the article PECTEN.

St. Michael's SHELL, in natural hiſtory, a name given by authors to a ſpecies of pecten, or ſcallop-*ſhell*. It is of a bright yellow colour. See PECTEN.

Scorpion-SHELL, in natural hiſtory, the name of a ſpecies of murex, very much approaching to the nature of the ſpider-*ſhell*. This is a common *ſhell* in cabinets. It is of a yellow colour, and very deeply ridged, and full of tubercles; there ariſe from the lip of the *ſhell* five large ſpines, or, as they are uſually called, fingers, and two others, which are very much bent, the one from the head, the other from the tail: theſe are very elegantly radiated with white and a fine violet colour on the lips. See the article MUREX.

Screw-SHELL. See the article TURBO.

Small-pox-SHELL, in natural hiſtory, a name given to a remarkable kind of concha venerea, or porcelain-*ſhell*, the protuberances on the ſurface of which are ſuppoſed to repreſent the puſtules of the ſmall-pox. There are two ſpecies of this *ſhell*, the one white with flattiſh protuberances, the other greeniſh with more elevated ones. See the article PORCELLANA.

Snake-SHELL, in natural hiſtory, the name given by many to that beautiful ſpecies of porcelain-*ſhell*, the ſpots of which repreſent thoſe of a ſnake's ſkin. See the article PORCELLANA.

Spider-SHELL, the name of a kind of murex. See the articles ARANCHA, CONCHA, and MUREX.

Strawberry-SHELL, in natural hiſtory, a name given by collectors of *ſhells* to a very beautiful ſpecies of cordiformis, ſpotted with ſmall round red ſpots.

Swallow-SHELL, in natural hiſtory, the name given by authors to a ſpecies of oiſter, which in ſome degree repreſents the figure of a ſmall bird flying. See OSTREA.

Swan-SHELL. See the article CIGNE.

Tiger-SHELL, in natural hiſtory, the name of a ſpecies of porcelain, or concha venerea, ſuppoſed to repreſent the ſpots on a tiger's ſkin. See PORCELLANA.

Trumpet-SHELL. See the article TRUMPET.

Turban-SHELL. See the article TURBAN.

Turnep-SHELL. This is a ſpecies of ſea-*ſhell*, by others called the *radiſh-ſhell*. It is exactly of the ſhape of a turnep, and is of the dolium, or concha globoſa kind. Thoſe who have called it the *radiſh-ſhell*, allude to the great black roundrooted radiſh, not to our common radiſh. See the article DOLIUM.

SHELL-*apple*, in zoology, an Engliſh name for the loxia, or croſsbill; given from his manner of ſplitting an apple, and feeding on the kernels, leaving the *ſhell* of the pulp untouched. *Ray's* Ornitholog. p. 181. See the article LOXIA.

SHELL-*drake*, in zoology, a common Engliſh name for the tadoma. See the article TADOMA.

SHELL-*fiſh*. Theſe animals are in general oviparous, very few inſtances having been found of ſuch as are viviparous. Among the oviparous kinds, anatomiſts have found that ſome ſpecies are of different ſexes in the different individuals of the ſame ſpecies, but others are hermaphrodites, every one being in itſelf both male and female: in both caſes their encreaſe is very numerous, and ſcarce inferior to that of plants, or of the moſt fruitful of the inſect claſs. The eggs are very ſmall, and are hung together in a ſort of cluſters by means of a glutinous humour, which is always placed about them, and is of the nature of the jelly of frogs ſpawn; by means of this they are not only kept together in the parcel, but the whole cluſter is faſtened to the rocks, *ſhells*, or other ſolid ſubſtances, and thus they are preſerved from being driven on ſhore by the waves, and left where they cannot ſucceed. *Langius*, Method. Teſtac.

SHELL-*gall-inſect*, an inſect of the gall-inſect claſs, ſomewhat reſembling thoſe which are called the boat-faſhioned ones, but differing in this, that as the two ends of that ſpecies are not very different in form, in this kind one of the ends is ſharp and pointed, in compariſon with the other. It has its name of *ſhell-inſect*, from the reſemblance it bears to a muſcle-*ſhell*; as it is, in its whole form, not unlike one of the two *ſhells*, in which the common ſea-muſcle is encloſed, but the pointed end of this *inſect* is much more extended in length, than the ſmaller end of this *ſhell*.

This ſpecies is extremely ſmall, and may be eaſily miſtaken for the minute caſe, out of which ſome ſmall inſect has eſcaped; or in another ſtate, for the neſt in which ſome ſmall inſect had depoſited its eggs: but if the aſſiſtance of the microſcope be called in, they will eaſily be diſcovered to be true gall-inſects, even as ſoon as they are hatched from the eggs. This ſpecies, at its full growth, is ſo ſmall, that it requires good eyes to diſcover it. It is brown, very ſmooth, and poliſhed on the ſurface, and much of the colour of the bark of ſome trees. It has uſually an edge of a cottony matter, viſible where its ſides touch the tree, and its eggs are always depoſited on a fine cottony bed. The young ones are white, flat, and have two ſmall horns, and ſix legs. In this ſtate they are known to be of the gall-inſect claſs; not by their likeneſs to their parent, but to the young gall-inſects of other ſpecies. They march about very briſkly for ſome time after they are hatched, and after that fix themſelves, and then begin to grow, and by degrees alter their form, till they at length are of the ſame ſhape with their parent. *Reaumur*, Hiſt. Inſ. Tom. 4. p. 69, 70.

SHELL-*ſand*, a name given by the farmers, in ſome parts of England, to the fragments of *ſhells* found on the ſea-ſhores, and ground to a ſort of powder, ſo that they reſemble ſand. There is alſo another kind uſed as this is, in ſome parts of Cornwall, and compoſed of fragments of a ſort of tender white coral This is found principally about Falmouth, and is called by the ſame name of *ſhell-ſand*, though very improperly. All the kinds are of great uſe in agriculture, but they are differently eſteemed by the farmers, as they are more or leſs rich, which they know by their colours. The reddiſh kind is eſteemed moſt of all, next to this the blue is judged the beſt, and after this the white. Such as is dredged up from under the water, is always found better, than ſuch as is found dry on the ſhores; and ſuch as is entirely compoſed of *ſhells* is to be choſen, rather than ſuch as has fragments of ſtone among it, which is a very common caſe.

In Cornwall they uſe this as the general manure of their land; they carry it up in lighters as near the lands, where it is to be uſed, as they can, and thence it is ſometimes carried to the place, where it is to be uſed, by carts, and ſometimes by men with horſes, a horſe being able eaſily to carry thirteen gallons of it at a load. One man drives ſeven or eight of thoſe horſes in a train, and the farmers find it worth their while to carry it ten or twelve mile from the water ſide in this manner. At this diſtance it uſually coſts about eight pence the load, but where the lands lie near the water, the price is very inconſiderable. So much of this *ſand* is uſed in the county of Cornwall, that the land-carriage alone, at this eaſy rate, is found to amount to more than thirty thouſand pounds a year, and the advantages from it is very great; ſo that it is wonderful, that the practice is not extended all over the kingdom where the ſea-coaſts are near. Phil. Tranſ. N° 113.

SHELL-*toothed*, in the manege, an appellation given to a horſe that from five years old to old age naturally, and without any artifice, bears mark in all his fore teeth, and there ſtill keeps that hollow place with the black mark, which is called in French *germe de feve*, i. e. the eye of a bean; inſomuch, that at twelve or fifteen he appears with the mark of a horſe that is not yet ſix: for in the nippers of other horſes, the hollow place is filled, and the mark diſappears, towards the ſixth year, by reaſon of the wearing of the tooth. About the ſame age it is half worn out in the middling teeth, and towards the eighth year it diſappears in the corner teeth: but after a *ſhell-toothed* horſe has marked, he marks ſtill equally in the nippers, the middling, and the corner teeth; which proceeds from this, that having harder teeth than other horſes, his teeth do not wear, and ſo he does not loſe the black ſpot. Among the Poliſh, Hungarian, and Croatian horſes, we find a great many of them hollow-toothed; and generally the mares are more apt to be ſo than the horſes.

SHELTIE, the name of a ſmall, but ſtrong kind of horſe, found in the iſland of Zetland, commonly called *Shetland*. In the country, the price of one of theſe horſes is about a guinea. Phil. Tranſ. N° 473. ſect. 8.

SHERARDIA, in the Linnæan ſyſtem of botany, a diſtinct genus of plants, the characters of which are, that the cup is a ſmall perianthium, divided into four ſegments, ſituated on the germen, and remaining after the flower is fallen. The flower conſiſts of one petal, which is a long cylindric tube, divided into four ſegments at the end; the ſegments are pointed, and the flower placed flatwiſe. The ſtamina are four

four filaments, placed at the upper part of the tube. The antheræ are fimple. The germen of the piftil is double, oblong, and placed below the receptacle. The ftyle is flender, and bifid at top; and the ftigmata are headed. The fruit is an oblong body, feparable longitudinally into two feeds, which are long, convex on one fide, and plane on the other, and marked with three points at their fummit. *Linnæi* Gen. Plant. p. 25.

SHERARDIA is alfo a name given by Pontedera to the genus of plants, called by Linnæus *galenia*. *Ponteder*. Epift. 14. See the article GALENIA.

SHERIF, in the Egyptian orders, the relations of Mahomet, the fame tribe of perfons called *emir* by the Turks.

The word is Perfian, and fignifies great or noble; and thefe perfons have the privilege of being exempt from appearing before any judge but their own head: and if any of the military orders are obliged to punifh them for any mifdemeanor, they firft take off their green turban, in refpect to their character; and the fame is done, even when they are punifhed by their own magiftrate. *Pocock*'s Egypt, p. 171.

SHIELD (*Cycl.*)—The *fhield* was that part of the antient armour, on which the perfons of diftinction in the field of battle always had their arms painted; and moft of the words, ufed at this time to exprefs the fpace that holds the arms of families, are derived from the Latin name for a *fhield*, *fcutum*. The French *efcu*, and *efcuffion*, and our Englifh word, *efcutcheon*, or, as we commonly fpeak it, *fcutcheon*, is evidently from this origin; and the Italian *fcudo* fignifies both the *fhield* of arms, and that ufed in war.

The Latin name *clypeus*, for the fame thing, feems alfo to be derived from the Greek word, γλυφειν, to engrave; and it had this name from the feveral figures engraved on it, as marks of diftinction of the perfon who wore it. *Beckman*, Diff. 6. cap. 8.

The *fhield* in war, among the Greeks and Romans, was not only ufeful in the defence of the body, but it was alfo a token, or badge of honour to the wearer, and he who returned from battle without it, was always treated with infamy afterwards.

People have at all times thought this honourable piece of the armour, the propereft place to engrave, or figure on the figns of dignity of the poffeffor of it; and hence, when arms came to be painted for families in after-times, the heralds always chofe to reprefent them upon the figure of a *fhield*, but with feveral exterior additions and ornaments, as the helmet, fupporters, and the reft. *Nifbet*'s Heraldry, p. 11.

The form of the *fhield* has not only been found different in various nations, but even the people of the fame nation, at different times, have varied its form extremely; and among feveral people there have been *fhields* of feveral forms and fizes in ufe, at the fame period of time, and fuited to different occafions. *Baron*'s Heraldry.

The moft antient and univerfal form of *fhields*, in the earlier ages, feems to have been the triangular. This we fee inftances of in all the monuments and gems of antiquity: our own moft early monuments fhew it to have been the moft antique fhape alfo with us, and the heralds have found it the moft convenient for their purpofes, when they had any odd number of figures to reprefent; as if three, then two in the broad bottom part, and one in the narrow upper end, it held them very well; or if five, they ftood as conveniently at three below, and two above. The other form of a *fhield*, now univerfally ufed, is fquare, rounded and pointed at the bottom: this is taken from the figure of the famnitic-*fhield* ufed by the Romans, and fince copied very generally by the Englifh, French, and Germans. The Spaniards and Portuguefe have the like general form of *fhields*, but they are round at the bottom without the point; and the Germans, befide the famnite-*fhield*, have two others pretty much in ufe: thefe are, 1. The bulging-*fhield*, diftinguifhed by its fwelling or bulging out at the flanks; and 2. the indented-*fhield*, or *fhield* chancrée, which has a number of notches and indentings all round its fides. The ufe of the antient *fhield* of this form was, that the notches ferved to reft the lance upon, that it might be firm while it gave the thruft; but this form being lefs proper for the receiving armorial figures, the two former have been much more ufed in the heraldry of that nation.

Befide this different form of the *fhields* in heraldry, we find them alfo often diftinguifhed by their different pofitions, fome of them ftanding erect, and others flanting various ways, and in different degrees. This the heralds exprefs by the word *pendant*, hanging, they feeming to be hung up not by the center, but by the right or left corner. The French call thefe *ecu pendant*, and the common antique triangular ones *ecu ancien*. The Italians call this *fcuto pendente*; and the reafon given for exhibiting the *fhield* in thefe figures in heraldry is, that in the antient tilts and tournaments, they who were to juft at thefe military exercifes, were obliged to hang up their *fhields*, with their armories, or coats of arms on them, out at the windows and balconies of the houfes near the place; or upon trees, pavilions, or the barriers of the ground, if the exercife was to be performed in the field.

Thofe who were to fight on foot, according to Columbier, had their *fhields* hung up by the right corner, and thofe who were to fight on horfeback, had theirs hung up by the left. This pofition of the *fhields*, in heraldry, is called *couché* by fome writers, though by the generality *pendant*.

It was very frequent, in all parts of Europe, in arms given between the eleventh and fourteenth centuries. But it is to be obferved, that the hanging by the left corner, as it was the token of the owner's being to fight on horfeback, fo it was efteemed the moft honourable and noble fituation, and all the pendant *fhields* of the fons of the royal family of Scotland and England, and of our nobility at that time, are thus hanging from the left corner. The hanging from this corner, was a token of the owner's being of noble birth, and having fought in the tournaments before; but no fovereign ever had a *fhield* pendant any way, but always erect, as they never formally entered the lifts of the tournament.

The Italians generally have their *fhields* of arms of an oval form: this feems to be done in imitation of thofe of the popes, and other dignified clergy; but their herald, Petro Sancto, feems to regret the ufe of this figure of the *fhield*, as an innovation brought in by the painters and engravers, as moft convenient for holding the figures, but derogatory to the honour of the poffeffor, as not reprefenting either antiquity, or honours won in war, but rather the honours of fome citizen, or perfon of learning. Some have carried it fo far, as to fay that thofe, who either have no antient title to nobility, or have fullied it by any unworthy action, cannot any longer wear their arms in *fhields* properly figured, but were obliged to have them painted in an oval, or round *fhield*. In Flanders, where this author lived, the round and oval *fhields* are in the difrepute he fpeaks of; but in Italy, befide the popes and dignified prelates, many of the firft families of the laity have them. The fecular princes, in many other countries, alfo retain this form of the *fhield*, as the moft antient, and truly expreffive of the Roman clypeus. *Nifbet*'s Heraldry, p. 12. *Componille*, Herald.

SHIFTERS, on board a man of war, certain men who are employed by the cooks to fhift or change the water, in which the flefh or fifh is put, and laid for fome time, in order to fit it for the kettle.

SHILLING (*Cycl.*)—In the year 1560, there was a peculiar fort of *fhilling* ftruck in Ireland, of the value of nine pence Englifh, which paffed in Ireland for twelve pence. The motto on the reverfe of thefe, is *pofui deum adjutorem meum*. Eighty two of thefe *fhillings*, according to Malynes, went to the pound; they therefore weighed twenty grains one fourth each, which is fomewhat heavier in proportion than the Englifh *fhilling* of that time, fixty two whereof went to the pound, each weighing ninety two grains feven eighths; and the Irifh *fhilling* being valued at the Tower at nine pence Englifh (that is one fourth part lefs than the Englifh *fhilling*) it fhould therefore proportionably weigh one fourth part lefs, and its full weight be fomewhat more than fixty two grains, but fome of them found at this time, though much worn, weighed fixty nine grains. In the year 1598, five different pieces of money of this kind were ftruck in England for the fervice of the kingdom of Ireland.

Thefe were *fhillings* to be current in Ireland as twelve pence each, half *fhillings* to be current at fix pence, and quarter *fhillings* at three pence. Pennies and halfpennies were alfo ftruck of the fame kind, and fent over for the payment of the army in Ireland. The money thus coined was of a very bafe mixture of copper and filver, and two years after there were more pieces of the fame kinds ftruck for the fame fervice, which were ftill worfe; the former being three ounces of filver to nine ounces of copper, and thefe latter only two ounces eighteen pennyweights, to nine ounces two pennyweights of the alloy. *Simon*'s Irifh Coins.

SHINGLING, in the iron-works, in many parts of England, is the operation of hammering the fow, or caft-iron, into blooms. The tongs, ufed for holding the iron in this operation, are called *fhingling-tongs*, and the iron to be thus wrought is called a *loop*. *Ray*'s Englifh Words, p. 128. See the articles LOOP and BLOOM.

SHIP (*Cycl.*)—It is highly neceffary, to the health of feamen, that *fhips* fhould be cleared of foul air; for it has been found by frequent experience, that air fhut up, and confined in a clofe place, without a fucceffion and frefh fupply of it, becomes unwholfome, and unfit for the ufe of life. This is more fenfibly fo, if any ftagnating water be pent up with it. But it grows ftill worfe, if fuch an air as this is made ufe of in refpiration; that is, becomes moifter and hotter, by paffing and repaffing through the lungs. Thefe bad effects in different degrees, according to the different manner in which air is inclofed, are obferved in many cafes; particularly in deep wells, and caverns of the earth; in prifons, or clofe houfes, where people are fhut up with heat and naftinefs; but moft of all in large *fhips*, in which, with the ftench of water in the hold, many men being crouded up in clofe quarters, all the mentioned circumftances concur in producing greater mifchiefs than would follow from any of them fingle.

Mr.

Mr. Sutton did therefore, a few years ago, propofe, in order to clear the holds of *fhips* of the bad air they contain, that the fire-place and afh-place of the copper or boiler fhould be both clofed up with fubftantial and tight iron doors; and that a copper, or leaden-pipe, of fufficient fize, fhould be laid from the hold into the afh-place, for the draught of air to come in that way to feed the fire. And thus, from the natural elafticity of the air, it feems plain, that there will be from the hold a conftant difcharge of the air therein contained; and confequently, that the air fo difcharged muft be as conftantly fupplied by frefh air below the hatches, or fuch other communications as are open into the hold; whereby the fame muft be continually made frefh, and its air rendered more wholfome, and fit for refpiration. And if into this principal pipe, fo laid into the hold, other pipes are let in, communicating refpectively either with the well, or lower decks, it muft follow, that part of the air, confumed in feeding the fire, muft be refpectively drawn out of all fuch places, to which the communication fhall be fo made. Phil. Tranf. N° 462. p. 42, 43.

To prevent *fhips*, whofe bottoms are worm-eaten, from leaking, this method has been propofed [b]. Calk well the infide planks, or lining; then fill the vacant fpaces between the timbers, and the out and infide planks with boiling pitch, or refin, fo high as the main-gun-deck. The pitch being put in very hot, will run into the fmalleft cranny, and make the *fhip* as tight as a bottle. There will be no room left for vermin, as rats, &c. and the pitch will ferve for other ufes when taken out; therefore the expence will be but fmall.—[[b] Phil. Tranf. N° 476. p. 372.]

SHIP *of pleafure*, among the antients. See the article THALAMEGUS.

SHIP, in the falt-works, is a large ciftern, out of which the falt-pans are fupplied for boiling.

This ciftern is built clofe to the faltern, and is made either of wood, brick, or clay; and it ought always to be covered with a fhed, that the fea water, contained in it, may be kept clean from foot, and other impurities, and not mixed with frefh water in rains; and it muft be always placed fo high, that the water will eafily run out of it into the pans, to fupply them for boiling.

SHIRE (*Cycl.*)—SHIRE-*clerk*, he that keeps the county-court; and his office is fo incident to that of the fheriff, that the king cannot grant it away. 4 Rep. *Blount*, *Cowel.*

SHIRE-*man*, was antiently the judge of the *fhire*, by whom trials for land, &c. were determined. Lamb. Peramb. 442. *Blount.*

SHIRE-*mote*, in our old writers, an affembly of the county or *fhire* at the affizes, &c. *Blount*, *Cowel.* See the article SCYREGEMOT, *Cycl.*

SHIVERS, in a fhip, the feamen's term for thofe little round wheels, in which the rope of a pulley or block runs. They turn with the rope, and have pieces of brafs in their centers, (which they call the *cocks*) with holes in them, into which the pin of the block goes, and on which they turn.

Thefe *fhivers* are ufually of wood; but fome are of brafs, as thofe in the heels of the top-mafts.

SHIVERY *falt*, a name given by the falt-workers to a fort of falt, very little different from the common brine-falt.

It is prepared in the fame manner, as that falt from the falt fprings in Chefhire, and other places, and is of a larger and firmer grain than that prepared in the common way, and is ftronger, and therefore more fit for the preferving meat. When they would make this *falt*, they fill the pans on Saturday night, and then, as they draw out no falt on Sundays, there is a very moderate fire kept up all that day, and on the Monday morning all the *falt* is taken out at one draught, having had time to form itfelf into larger cryftals than ordinary, as it is eight and forty hours, inftead of four and twenty in forming. *Brownrig* of Salt, p. 108. See the article SALT.

SHOAD, in mining, a term for a train of metalline ftones mixed with earth, fometimes lying near the furface, fometimes at confiderable depths; but always ferving to the miners as a proof, that the load or vein of the metal is thereabout. The deeper the *fhoad* lies, the nearer ufually the vein is. *Ray's* Words, p. 120.

SHOAD-*ftones*, a term ufed by the miners of Cornwall, and other parts of this kingdom, to exprefs fuch loofe maffes of ftone, as are ufually found about the entrances into mines, fometimes running in a ftrait courfe, from the load or vein of ore, to the furface of the earth.

Thefe are ftones of the common kinds, appearing to have been pieces broken from the ftrata, or larger maffes, but they ufually contain mundic, or marcafitic matter, and more or lefs of the ore to be found in the mine. They appear to have been at fome time rolled about in water, their corners being broken off, and their furface fmoothed and rounded. The antimony mines in Cornwall are always eafily difcovered by the *fhoad-ftones*, thefe ufually lying up to the furface, or very nearly fo; and the matter of the *ftone* being a white fpar, or debafed cryftal, in which the native colour of the ore, which is a fhining bluifh black, eafily difcovers itfelf in ftreaks and threads.

Shoad-ftones are of fo many kinds, and of fuch various appearances, that it is not eafy to defcribe, or know them; but the miners, to whom they are of greateft ufe in the tracing, or fearching after new mines, diftinguifh them from other ftones by their weight: for if very ponderous, though they look ever fo much like common ftones, there is great reafon to fufpect that they contain fome metal. Another mark of them, is their being fpungy and porous; this is a fign of efpecial ufe in the tin countries, for the tin *fhoad-ftones* are often fo porous and fpungy, that they refemble large bones of animals thoroughly calcined. There are many other appearances of tin *fhoads*, the very hardeft and firmeft *ftones* often containing this metal.

When the miners, in tracing a *fhoad* up a hill, meet with fuch odd ftones and earths, that they know not well what to make of them, they have recourfe to vanning, that is, they calcine and powder the ftone, clay, or whatever elfe is fuppofed to contain the metal; and then wafhing it in an inftrument, prepared for that purpofe, and called a *vanning-fhovel*, they find the earthy matter wafhed away; and of the remainder, the ftoney, or gravelly matter lies behind, and the metalline matter at the point of the fhovel. If the perfon, who performs this operation, has any judgment, he eafily difcovers not only what the metal is that is contained in the *fhoad*, but alfo will make a very probable guefs at what quantity the mine is likely to yield of it, in proportion to the ore. Phil. Tranf. N° 69.

SHOE (*Cycl.*)—SHOE, in the manege. A horfe-*fhoe* is a piece of flat iron, with two branches or wings, which being commonly forged according to the form of the hoof for which it is defigned, is made round at the toe, and open at the heel.

A *fhoe* for all feet, is one that is cut at the toe into two equal parts, which are joined by a riveted nail; upon which they are moveable in fuch a manner, that the *fhoe* is inlarged or contracted, lefs or more, at pleafure, in order to make it fit all forts and fizes of feet.

To *fhoe* a horfe after the form of a lunette, a patin, &c. See LUNETTE, PATIN, &c.

SHOEING-*hammer*, in the manege, a hammer that the fmith or farrier makes ufe of to adjuft and fit the fhoes upon the anvil, both hot and cold.

SHOOT, in the fea language. They fay the ballaft *fhoots*, when it runs over from one fide to another.

SHOOTING (*Cycl.*)—SHOOTING *of falts*. It is to be obferved, that the figures arifing from the *fhooting* of diffolved falts are not conftantly the fame, but vary according to different circumftances; fuch as when they happen to *fhoot* more or lefs haftily, or in different proportions of liquor. *Boyle's* Works Abridged, Vol. I. p. 241. See the article SALT.

SHORES (*Cycl.*)—The *fhores* of the fea are divided, by Count Marfigli, into three portions, according to which all his defcriptions, in his accounts of the bafon of the fea, are given.

The firft part of the *fhore*, is that tract of land to which the fea juft reaches in ftorms and high tides, but which it never covers; the fecond part of the *fhore*, is that which is covered in high tides and ftorms, but is dry at other times; and the third is the defcent from this, which is always covered with water.

The firft part is only a continuation of the continent, and fuffers no alteration from the neighbourhood of the fea, except that it is rendered fit for the growth of fome plants, and wholly unfit for that of others, by the faline fteams and impregnations; and it is fcarce to be conceived by any, but thofe who have obferved it, how far in land the effects of the fea reach, fo as to make the earth proper for plants, which will not grow without this influence; there being feveral plants frequently found on high hills, and dry places, at three, four, and more miles from the fea, which yet would not grow, unlefs in the neighbourhood of it, nor will ever be found elfewhere.

The fecond part or portion of the *fhores* is much more affected by the fea than the former, being frequently wafhed and beaten by it. Its productions are rendered falt by the water, and it is covered with fand, or with the fragments of fhells in form of fand, and in fome places with a tartarous matter depofited from the water, and the colour of this whole extent of ground is ufually dufky and dull, efpecially where there are rocks and ftones; and thefe are covered with a flimy matter.

The third part of the *fhores* is more affected by the fea than either of the others, and is covered with an uniform cruft of the true nature of the bottom of the fea, except that plants and animals have their refidence in it, and the decayed parts of thefe alter it a little.

SHORLING *and morling*, in our old writers, words ufed to diftinguifh fells of fheep; *fhorling*, being the fells after the fleeces are fhorn off the fheeps back; and *morling*, the fells flead off after they die, or are killed: in fome parts of England, they underftand by a *fhorling*, a fheep whofe fleece is fhorn off; and by a *morling*, a fheep that dies. Stat. 3 Ed. 4. c. 1. *Blount.* See MORLING.

SHORT (*Cycl.*)—SHORT-*jointed*, in the manege. A horſe is ſaid to be *ſhort-jointed*, that has a ſhort paſtern. When this joint, or the paſtern, is too ſhort, the horſe is ſubject to have his fore-legs, from the knee to the cronet, all in a ſtrait line. Commonly your *ſhort-jointed* horſes do not manege ſo well as the *long-jointed*; but out of the manege the *ſhort-jointed* are the beſt for travel or fatigue.

SHORT-*ſightedneſs*.—A learned author thinks it probable, that out of ſo great a number of *ſhort-ſighted* perſons as are daily to be met with, few are born ſo. For it generally grows upon young people at the age of twenty or twenty-five, and therefore might poſſibly be prevented by uſing their eyes, while young, to all ſorts of conformations; that is, by often looking through glaſſes of all ſorts of figures, and by reading, writing, or working with ſpectacles, of ſeveral degrees of convexity. For whatever be the powers by which the eye conforms itſelf to diſtinct viſion, they may poſſibly grow weak, or loſe their extent one way or other, for want of variety of exerciſe. It ſeems an opinion, without foundation, to think that ſuch an exerciſe of the eyes can any wiſe injure them; provided, due care be taken to avoid looking at objects that are too bright. See Dr. Smith's Optics, Vol. 2. Rem. p. 10.

Short-ſightedneſs may come by accidents. Of this we have a remarkable inſtance, mentioned by Dr. Briggs in his Ophthalmographia, of a perſon, upwards of ſeventy years old, who had uſed ſpectacles for ten years, and yet by catching cold, he ſuddenly became ſo *ſhort-ſighted*, that he could not diſtinguiſh objects three feet off; and after the cold and defluxion were cured, he continued to read the ſmalleſt print without ſpectacles for many years. Dr. Smith mentions a young gentleman, who became *ſhort-ſighted* immediately after coming out of a cold bath, in which he did not totally immerſe himſelf, and has ever ſince uſed a concave glaſs for many years. Ibid.

It is commonly thought that *ſhort-ſightedneſs* wears off in old age, but the learned Doctor queſtions whether this be matter of fact, or hypotheſis only. Ibid.

It is remarkable, that *ſhort-ſighted* perſons commonly write a ſmall hand, and love a ſmall print, becauſe they can ſee more of it at a view. That it is cuſtomary with them not to look at the perſon they converſe with, becauſe they cannot well ſee the motion of his eyes and features, and are therefore attentive to his words only. That they ſee more diſtinctly, and ſomewhat farther off, by a ſtrong light, than by a weak one; becauſe a ſtrong light cauſes a contraction of the pupil, and conſequently of the pencils, both here, and at the return; which leſſens their mixture, and conſequently the apparent confuſion: and therefore to ſee more diſtinctly, they almoſt cloſe their eye-lids; for which reaſon they were antiently called *myopes*. Ibid. ſect. 62.

Dr. Jurin obſerves, that perſons who are much, and long accuſtomed to view objects at ſmall diſtances; as ſtudents in general, watchmakers, gravers, painters in miniature, &c. ſee better at ſmall diſtances, and not ſo well at great diſtances, as the reſt of mankind. The reaſon is, that in the eye, as well as in other parts, the muſcles, by conſtant exerciſe, are enabled to contract themſelves with more ſtrength, and by diſuſe are brought to leſs ſtrength. Hence, in the perſons beforementioned, the greater muſcular ring of the uvea contracts more eaſily and ſtrongly, and the cornea more readily obeys the contraction of the ring; whence they ſee better at ſmall diſtances. And the cornea, by being thus often and long bent into a greater convexity, does by degrees loſe ſomething of its elaſticity, ſo as not to return to its natural elaſticity, when the muſcular ring ceaſes to act upon it. This is one cauſe of their not ſeeing ſo well at great diſtances. Alſo the ligamentum ciliare, being ſeldom employed to leſſen the convexity of the capſula, does by degrees become leſs capable of performing that office: and the capſula being ſeldom drawn out, and put into tenſion, muſt loſe ſomething of its diſtenſile quality, ſo as leſs eaſily to comply with the action of the ligament. And this is another cauſe of their not ſeeing ſo well at great diſtances. *Jurin*, Eſſ. on diſt. and indiſt. Viſion.

SHORTFORD, an antient cuſtom in the city of Exeter, when the lord of the fee cannot be anſwered rent due to him out of his tenement, and no diſtreſs can be levied for the ſame. The lord is then to come to the tenement, and there take a ſtone, or ſome other dead thing off the tenement, and bring it before the mayor and bailiff, and thus he muſt do ſeven quarter-days ſucceſſively; and if on the ſeventh quarter-day, the lord is not ſatisfied his rent and arrears, then the tenement ſhall be adjudged to the lord to hold the ſame a year and a day; and forthwith proclamation is to be made in the court, that if any man claims any title to the ſaid tenement, he muſt appear within the year and day next following, and ſatisfy the lord of the ſaid rent and arrears. But if no appearance be made, and the rent not paid, the lord comes again to the court and prays that, according to the cuſtom, the ſaid tenement be adjudged to him in his demeſne as of fee, which is done accordingly; ſo as the lord hath from thenceforth the ſaid tenement, with the appurtenances, to him and his heirs.

SHOT (*Cycl.*)—SHOT *of a cable*, on ſhip-board, is the ſplicing of two cables together, that a ſhip may ride ſafe in deep waters and in great roads; for a ſhip will ride eaſier by one *ſhot of a cable*, than by three ſhort cables out a-head.

SHOVELER, in zoology, the name of a ſpecies of ſea-duck, remarkable for the breadth of its bill, and called by authors *anas latiroſtra*, the broad-beaked duck, and *taſchenmul*, and by ſome *anas clypeata*.

It is ſomething ſmaller than the common duck. The beak is remarkably broad, and grows broader and rounder toward the end, where it is hollowed like a ſhield. The iris of its eyes is very yellow, and the legs and feet red. The feet are ſmaller than in moſt other ducks. The head, and upper part of the neck, are of a very beautiful blue, ſometimes of a duſky green; the under part of the neck is white, the upper and the ſhoulders variegated with white and brown. The belly, and lower part of the breaſt, are red, but the feathers behind the anus, and immediately under the tail, are black. The back is brown, with a fine caſt of blue, purple and green. The tail is ſhort, and is variegated with black and white. *Ray*'s Ornithol. p. 280.

SHOULDER (*Cycl.*)—SHOULDER, in the manege, is the joint of a horſe's fore-quarters, that joins the end of the *ſhoulder*-blade with the extremity of the fore-thigh.

SHOULDER *of a branch*, is that part of it which begins at the lower part of the arch of the banquet, overagainſt the middle of the fonceau, or chaperon, and forms another arch under the banquet. The *ſhoulder of a branch* caſts a greater, or leſſer circumference, according as it is deſigned to fortify, or weaken the branch. See the articles BRIDLE, BANQUET, and BRANCH.

SHOULDER-*pegged horſes*, called in French *chevillées*, are ſuch as have their *ſhoulders* gourdy, ſtiff, and almoſt without motion. A horſe charged with *ſhoulders*, is one that has thick, fleſhy, and heavy *ſhoulders*.

Cartilages of the SHOULDER, in anatomy. The ſcapula in many ſubjects has a ſmall cartilaginous border along its whole baſis, which in children is remarkable enough, but in grown perſons it diſappears. The glenoide cavity of this bone is covered with a cartilage, which is thicker toward the circumference than in the middle, and a little raiſed above the edge of the bone. The ſmall cartilaginous ſurface of the acromion is thicker in freſh bones, than it appears in a dried ſceleton, and is a little convex. The ſmall triangular ſurface, at the extremity of the ſpine of the ſcapula, near the baſis, is covered with a very thin, ſmooth cartilaginous lamina; but this being tranſparent, does not appear very white. There are no other cartilages but theſe uſually found in the ſcapula in freſh ſubjects, notwithſtanding that in ſceletons of prepared bones, ſeveral places beſide ſeem to have been cartilaginous; theſe, however, are owing only to the dried remains of ligaments and tendons. *Winſlow*'s Anatomy, p. 137.

Ligaments of the SHOULDER. The articulation of the acromium with the extremity of the clavicle, is ſtrengthened all round by ſeveral ſmall, but ſtrong ligaments, which go directly from one bone to the other. Theſe ligaments lie very near one another, and withal are ſo tightly braced over the joint, as to hide it altogether: they appear indeed more like a cartilaginous covering, than a ligamentary texture; and the internal ſurface of theſe ligaments is lined with the capſula of the joint. When the ſmall inter-articular cartilage is found in this joint, its whole circumference is ever found connected to theſe ligaments. The articulation of the clavicle with the ſternum is ſuſtained by ſeveral ligaments, fixed by one end round the pectoral extremity of the clavicle, and inſerted at the other in the ſternum. There is alſo a long narrow ſtrong ligament, which goes from one clavicle to the other, behind the furca of the ſternum: this is fixed to the internal angle of the contiguous extremities of the bones, and may be properly called the *inter-clavicular ligament*. The neck of the ſcapula, at a ſmall diſtance from the glenoide cavity, gives inſertion to the capſular ligament, or mucilaginous bag, and to the articular ligaments of the joint of the ſcapula and os humeri. And beſide theſe articular ligaments of the ſcapula, there are three ligamentary cords fixed to the tuberoſity of the coracoide apophyſis; two of which, by their other extremities, are inſerted in the oblique eminence on the lower ſide of the humeral extremity of the clavicle, the third under the acromium. There is alſo a thin flat broad ligament, reaching between the criſta of the ſpine of the ſcapula, and the edge of the inferior coſta. *Winſlow*'s Anatomy, p. 138.

SHOULDER *of a baſtion*, in fortification, is where the face and the flank meet.

SHOUT, *clamor*, in antiquity, was frequently uſed both on eccleſiaſtical, civil and military occaſions, as a ſign of approbation, and ſometimes of indignation. Thus as Cicero, in an aſſembly of the people, was expoſing the arrogance of L. Antony, who had had the impudence to cauſe himſelf to be inſcribed the patron of the Romans, the people on hearing this raiſed a *ſhout*, to ſhew their indignation.

In the antient military diſcipline *ſhouts* were uſed, 1. upon occaſion of the general's making a ſpeech, or harangue to the army, from his tribunal. This they did in token of their approving

what had been propofed. 2. Before an engagement, in order to encourage and fpirit their own men, and fill the enemy with dread. This is a practice of great antiquity, befides which it wants not the authority of reafon to fupport it; for as mankind are endowed with two fenfes, hearing and feeing, by which fear is raifed in the mind, it may be proper to make ufe of the ear, as well as the eye, for that purpofe. *Shouts* were alfo raifed in the antient theatre, when what was acted pleafed the fpectators. See ACCLAMATION.

It was ufual, for thofe prefent at the burning the dead, to raife a great *fhout*, and call the dead perfon by his name, before they fet fire to the pile. See BURIAL.

SHREW, or SHREW-*moufe*, in zoology, the common name of the creature called by authors *mus araneus*. See the article MUS *araneus*.

Hardy SHREW. See the article HARDY.

SHRIKE, in zoology, an Englifh name for the lanius, or butcher-bird, a fmall bird of the hawk-kind, a terrible deftroyer of the little birds. *Ray's* Ornithol. p. 52. See the article LANIUS.

SHRITE, in zoology, a name ufed by fome for the larger thrufh, or *turdus vifcivorus major*, commonly known by the name of the *miffel-bird*. It ftays the whole year with us, and fings very fweetly. See MISSEL-*bird*.

SHRUB (*Cycl.*)—*Hardy* SHRUBS. See the article HARDY.

SI *action*, in law, the conclufion of a plea to the action, when the defendant demands judgment, if the plaintiff ought to have his action, &c.

SIAGONAGRA, a name given by fome medical writers to the gout in the jaws.

SIALISMUS, a word ufed by the antients to exprefs a difcharge of faliva, brought on by the holding hot things in the mouth; and by us for a falivation by mercury.

SIALOCHI, a term ufed by the antients to exprefs fuch perfons as had a plentiful difcharge of faliva, by whatever means. Hippocrates ufes it for a perfon in a quinfey, who difcharges a very large quantity of faliva; others exprefs by it perfons, whofe mouths naturally abound with a bitter faliva; and others fuch perfons, as from having a very large tongue, fpit into people's faces while talking with them.

SIALOGOGA, a term ufed by medical writers to exprefs fuch medicines as promote a copious difcharge of the faliva, fuch as pellitory of Spain, and all the other hot and acrid vegetables; and mercury, the moft powerful of all.

SIANKE, or SYNKE, in natural hiftory, a name given by the people of fome parts of the Eaft-Indies to the caryophyllus, or clove-fpice. The people of the Moluccas, according to Garcias, call it *chanque*, which is only a fmall difference of pronunciation. The Turks and Perfians call the fame fpice *calafur*.

SICCHASIA, a word ufed by fome writers to exprefs that uneafinefs at the ftomach, and loathing of food, which women are often afflicted with in their pregnancy.

SICCINNIS, in antiquity, a mixed kind of dance. See the article DANCE, *Cycl.*

SICERA, in the Jewifh antiquities. The hellenift Jews give this name to any inebriating liquor. St. Chryfoftom, Theodoret, and Theophilus of Antioch, who were Syrians, and who therefore ought to know the fignification and nature of *ficera*, affure us, that it properly fignifies palm-wine.

Pliny acknowledges, that the wine of the palm-tree was very well known through all the Eaft, and that it was made by taking a bufhel of the dates of the palm-tree, and throwing them into three gallons of water; then fqueezing out the juice, it would intoxicate like wine.

The wine of the palm-tree is white: when it is drank new, it has the tafte of the cocoa, and is fweet as honey: when it is kept longer, it grows ftrong, and intoxicates. After long keeping, it becomes vinegar. V. *Renaudot's* Notes upon the Voyage to China, p. 12. *Calm.* Dict. Bibl.

SICILIANA, in botany, a name given by Dodonæus, and fome other authors, to the great androfæmum, called *tutfan*, and *park-leaves*. *Ger.* Emac. Ind. 2.

SICILICUM, the name of a weight in ufe among the antients, which fome fay was equal to three drachms of our weight; others fay only to two.

SICUB, or SICAP, in natural hiftory, a name given by the inhabitants of the Philippine iflands to a fpecies of hawk, of the bignefs of their common hawk, or banoy, which is fomewhat larger than our fparrow-hawk. This bird is very elegantly variegated all over its body with yellow, white, and black.

SICUS, in ichthyology, a name ufed by fome authors to exprefs that fpecies of coregonus, called by the generality of authors *albula nobilis*. See the articles COREGONUS and ALBULA.

SICYOIDES, in botany, the name of a genus of plants, the characters of which are thefe. The flower confifts of one leaf, and is fhaped like a bell wide open at the mouth, and divided into feveral fegments. Some of the flowers on this plant are fteril, or male-flowers, having no embryo; others are fruitful, or female, having an embryo, which ripens into a fruit of the fhape of an almond, flefhy, prickly, ufually collected into a head, and containing only one feed under a thin fkin.

The fpecies of *ficyoides*, enumerated by Mr. Tournefort, are thefe. 1. The American *ficyoides* with angular leaves and echinated fruit, called by fome authors *cucumis Canadenfis monofpermos*, or the fingle-feeded Canada cucumber. 2. The American *ficyoides* with echinated fruit and deeply jagged leaves. *Tourn.* Inft. p. 103.

SICYONE, a word ufed by Hippocrates to exprefs colocynth, and by others for a fpecies of hard-fhelled gourd, in the fhape of a pear, and by fome for a cupping-glafs.

SICYONEUM *oleum*, a word ufed by the antients to exprefs a medicinal oil, of which there was among them three kinds in ufe. The firft was called *ficyonium fimplex*. This was compofed of two ounces of the root of the wild cucumber boiled feveral hours in a pint of oil. The fecond fort was called the *compound ficyonium*, and was made of the root of the fame plant, with many other ingredients. The third was another compound kind, made not with an infufion of the root, but with the juice of the fruit of the wild cucumber.

SICYONII, among the Romans, were fhoes of a more delicate form, and better ornamented than ordinary, and chiefly worn by the ladies and their gallants. *Pitifc.* in voc.

SIDA, in botany, the name of a genus of plants, conftituted by Linnæus, and comprehending the *malvinda* of Dillenius, and the *abutilon* of the fame author and of Tournefort. The characters are thefe: the perianthium is compofed of one leaf, of the figure of a cup, erect, and lightly divided into five fegments, and does not fall with the flower. The flower confifts of five petals, which are broad at the top, and furrounded with a rim: they are much narrower at the bottom, and grow together there. The ftamina are a great number of filaments, which at the bottom grow into a fort of tube, and at the top are free. The antheræ are roundifh. The germen of the piftil is roundifh. The ftyle is fhort, and is lightly divided into feveral fegments. The ftigmata are flender and obtufe. The fruit is a roundifh capfule, terminating in a point, and compofed of feveral horns, which finally feparating, tear the complex veffel to pieces. The feeds are roundifh and pointed, the one fide convex, and the other of an angular figure.

This genus is very nearly allied to the melochia, but differs in its numerous antheræ. The malvinda and abutilon agree in all the characters of this genus, but differ in this, that the firft has always only five capfules which compofe the general fruit, and the other has more. *Linnæi* Gen. Plant. p. 329. *Dillen.* Hort. Elth. p. 171. *Tournefort*, p. 25.

SIDA is alfo ufed by fome authors for the *althæa*, or marfhmallow. *Ger.* Emac. Ind. 2.

SIDE (*Cycl.*)—SIDES *of a fhip*, are diftinguifhed into the *ftarboard* and *larboard*; that is, into the right and left-hand-*fide*, when ftanding with the face towards the head of the veffel. See the articles STARBOARD and LARBOARD.

Broad-SIDE, in the fea language, is to fire all the guns on one *fide* of the fhip.

SIDE-*wind*, at fea. See the article WIND.

SIDERIA, in natural hiftory, the name of a genus of cryftal. The word is derived from the Greek, σίδηρος, iron, and is ufed to exprefs cryftals altered in their figure by particles of that metal. Thefe are of a rhomboidal form, compofed only of fix planes. Of this genus there are four known fpecies: 1. a colourlefs, pellucid, and thin one, found in confiderable quantities among the iron ores of the Foreft of Dean in Gloucefterfhire, and in other the like places. 2. A dull, thick, and brown one, not uncommon in the fame places with the former. And 3. a black and very gloffy kind, a foffil of very great beauty, found in the fame place with the others, as alfo in Leicefterfhire and Suffex. See Tab. of Foffils, Clafs 3. *Hill's* Hift. of Foff. p. 197.

SIDERITIS, (*Cycl.*) *iron-wort*, in botany, the name of a genus of plants, the characters of which are thefe. The flower confifts of one leaf, and is of the labiated kind. The upper lip is erect, the lower divided into feveral fegments. The piftil arifes from the cup, and is fixed in the manner of a nail into the hinder part of the flower, and furrounded by four embryos, which afterwards become fo many feeds, ripening in an open capfule, which was the cup of the flower. To thefe marks it may be added, that in all the *fiderites* the flowers grow in circles round the ftalks, at the joinings of the leaves.

The fpecies of *fideritis*, enumerated by Mr. Tournefort, are thefe. 1. The hairy procumbent *fideritis*, called *tetrahit* by many authors. 2. The hairy procumbent *fideritis* with leaves very flightly crenated. 3. The hairy *fideritis* with very deeply crenated leaves. 4. The hyffop-leaved Alpine *fideritis*. 5. The hyffop-leaved Alpine *fideritis* with leaves notched at the ends. 6. The narrower-leaved erect Spanifh *fideritis*. 7. The large procumbent Spanifh *fideritis* with crenated leaves, and white flowers. 8. The narrow-leaved crenated bituminofe *fideritis*. 9. The fmooth ftinking Spanifh *fideritis* with purple flowers, and hoary fpikes. 10. The woody fhrub Spanifh *fideritis*. 11. The fmall procumbent hyffop-

hyssop-leaved Pyrenean *sideritis*. 12. The mountain-*sideritis* with trifid leaves. 13. The tall yellow-flowered Canada *sideritis* with leaves like those of figwort. 14. The purple-flowered tall figwort-leaved Canada *sideritis*. There are some other plants, beside these, called by authors *sideritis*, but they are properly of the galeopsis, betony, or marrubiastrum-kind, which see. *Tourn.* Inst. p. 191.

SIDEROMANTIA, Σιδηρομαντεια, in antiquity, a kind of divination performed with a red-hot iron, upon which they laid an odd number of straws, and observed what figures, bendings, sparklings, &c. they made in burning. *Potter*, Archæol. Græc. l. 2. c. 18. Tom. I. p. 353.

SIDEWAYS, in the manege. To ride a horse *sideways*, is to passage him, or make him go upon two treads, one of which is marked by his shoulders, and the other by his haunches.

SIGAH-*gush*, in zoology, the name of a Persian animal, of the lynx-kind, and no way differing from the lynx itself, but in that it has no spots. Its ears have the fine velvety black pencil of hairs at their top, which are the distinguishing character of the lynx; and these creatures differ so much in the variations and different dispositions of their spots, that probably this is no other than an accidental variety of the same species. *Ray*'s Syn. Quad. p. 168.

SIGHT (*Cycl.*)—The Acta Leipsiensia give us an account of a man, who received a smart stroke on the pupil of one of his eyes from the end of a fiddle-string, which broke while he was tuning the instrument, and chanced to fly that way. Some cooling things were applied to the eye, and a bandage used to shade it from the light; but at midnight the patient chancing to wake in the dark, found that he could see with that eye, though not with the other: this continued a long time, and on trial he found that he could read a small print at midnight with this eye, but could scarce distinguish any thing with it in a bright and clear day.

We have, in the same collections, an account of a man, who, after the cure of a confirmed pox, saw every object double for a long time. Act. Leips. 1690.

It is a very common, and a very just observation, that children do not see any thing clearly when new-born, and if their eyes be then examined, they are found to want that brilliancy which they afterwards acquire; and finally, when any object is presented to their view, they at first turn their eyes about in such a manner, that it is evident they either do not see at all, or at best but very imperfectly and obscurely.

This imperfection may either be owing to a fault in some one of the humours, or in their capsules, or, finally, in the retina, or complexly in them all together. It is impossible to discover whether there be any imperfection in the retina in this state of life, that membrane being ever, in new-horn infants, tender and soft like a jelly: if it be in any of the other parts that the imperfection lies, it must be either in their nature, or extent. Mr. Petit, of the Academy of Sciences at Paris, determined to enquire thoroughly into the cause of this, was at the pains of dissecting the eyes of several infants which had died soon after their birth, and in three fourths of them he found the vitreous, the crystalline, and the capsule, all greatly deficient in their transparence. The uvea appeared also more opake than in adults, and the pupil over large; and that there was either none, or, at the utmost, very little of the aqueous humour: and in those eyes, where the humours had not this opacity, they were all, as were also the membranes, of a reddish colour; and this was observed in fœtuses of seven and nine months old.

The cornea in these eyes was also remarkably thick, which is, in general, found to be the case in the eyes of all fœtuses. The thickness and opacity in these corneas gradually diminish in time, and that soon; so that the eyes of children appear much brighter at two or three months old, than when new-born. The aqueous humour seems also, in most fœtuses, to be wholly wanting; and where it is found, is ever greatly in an under proportion to the other humours.

It therefore appears, that the dimness and imperfection of *sight*, in new-born infants, is owing to the over-thickness of the cornea, and to the too small portion of the aqueous or watery humour. It appears plainly also, from experience, that the eye is not able, in infants, to bear the light, till the pupil is greatly contracted; as is the case also, though in a less degree, in adults: and it is very probable, that the extreme softness of the retina in this state may make every ray of light affect it much more plainly, than when grown more firm.

Mr. Petit having continued his examinations of the eyes of infants, up to the age of five or six weeks, found in all his dissections, that the cornea daily grew more and more convex and glossy; and this may be rationally concluded to be owing to the daily encrease of the aqueous humour, which must, by that accretion, throw it out into a greater convexity, and make it daily more and more thin and transparent. The uvea also acquires a greater extension, and its fibres become more moveable; whence the pupil acquires a power of enlarging or contracting itself, at the approach or absence of light, with much more ease and readiness than it could before. The humours thus all become capable of letting in a larger quantity of light; the retina is at the same time every day gaining a new firmness, and the pupil becomes capable of an easy dilatation, or restriction, for the letting in occasionally a greater or less number of rays, and the refractions are perfected by the augmentation of the aqueous humour. It is plain, therefore, that the clearness of vision must every day encrease. All this change comes on in infants only by time; and it may be judged of, as to its state, by inspection, by the brilliancy and convexity of the cornea, and by the manner of their turning their eyes toward objects set before them: and this time is not certain, or limited, but differs greatly in different children, some being able to see clearly at the end of a month, others not till after many months.

At the time that this gentleman was dissecting the eyes of human fœtuses and infants, he also curiously observed the eyes of young quadrupeds. The puppy, when newly brought forth, has always its eyes opake; the kitten, on the contrary, has them clear, and every way like those of adults of the same species. In fœtuses of other quadrupeds, the lamb has its cornea a little turbid and opake; the calf and the pig have them more or less opake, but the calf most so of all. Mem. de l'Acad. Par. 1727.

SIGIA, a name given by some authors to the liquid-styrax.

SIGILLUM (*Cycl.*)—SIGILLUM *mariæ*, *lady's seal*, in botany, a name by which some authors have called the *bryonia nigra*, or black bryony, a climbing plant, common in hedges. *Ger.* Emac. Ind. 2.

SIGMA, among the Romans, the same with the *stibadium*. See the article STIBADIUM.

SIGMOIDES, a word used by medical writers to express any thing that is in the shape of the letter sigma. The valves of the heart have this epithet applied to them; the coracoide process of the scapula is also expressed by the same word; the semicircular cavity of the cubit, at the articulation of the fore-arm with the humerus, is sometimes also called the *sigmoidal-cavity*; and the cartilages of the *sigmoide*-circles of the *aspera arteria*, or wind-pipe, have their denomination from the same occasions.

SIGNS, or SYMPTOMS, in medicine. See ASSIDENT.

Negative SIGN. See the article NEGATIVE *sign*.

SIGNA, *standards*, among the Romans, were of different sorts; on some of them the image of the emperor was represented, and they that carried them were called *imaginiferi*; others had a hand stretched out, as a symbol of concord; and these ensign-bearers were called *signiferi*; some had a silver eagle, the bearers of which were called *aquiliferi*; others had a dragon with a silver head, and the rest of his body of taffety, which was blown by the wind as if it had been a real dragon, and the bearers of this ensign were called *draconarii*; lastly, the emperor's ensign was called *labarum*, and those that carried it *labariferi*, which they carried out when he went in person to the field: it was of a purple colour, beset with gold fringe, and adorned with precious stones.

All these ensigns were sustained with a half-pike, sharp at the end, that it might be the more easily fixed in the ground. *Danet.* in voc.

SIGNATORES, among the Romans, witnesses who sealed wills and marriage-contracts. *Pitisc.* in voc.

SIGNIFER, among the Romans, an ensign-bearer, or the person who carried the standard on which was represented a hand stretched out. See the article SIGNA.

SIGNINUM, among the Romans, a kind of pavement much esteemed: it was made of poudered shells mixed with lime. *Pitisc.* in voc.

SIGNUM *pugnæ*, the signal of battle, among the Romans, was a coat of arms, of a purple colour, set upon the general's pavilion. *Danet.* in voc.

SIGUETTE, in the manege, is a cavesson of iron, with teeth or notches; that is, a semicircle of hollow and vaulted iron, with teeth like a saw, consisting of two or three pieces joined with hinges, and mounted with a head-stall and two ropes, as if they were the cavessons that in former times were wont to be put upon the nose of a fiery stiff-headed horse, in order to keep him in subjection.

There is a sort of *siguette*, that is a round iron all of one piece, sewed under the nose-band of the bridle, that it may not be in view. This *siguette* we employ with a martingale, when a horse beats upon the hand.

SIL, in natural history, a name given by the antients to a red ochre, of which they had three distinct kinds, the *sil syricum*, *sil atticum*, and *sil marmorosum*; all of which are to be had at this time, and all very valuable paints.

SIL *syricum* is a substance well known among the painters of the present age, though not by name, being the red ochre, commonly used for a purple colour, in their coarser works; though it is capable of yielding, by proper management, a colour fit for their finest. It is very heavy, and of a fine strong red with some tendency to purple, of a loose friable texture,

texture, and very rough and dusty surface. It adheres firmly to the tongue, is somewhat soft to the touch, crumbles easily to pieces between the fingers, and stains the hands very much. It melts freely in the mouth, and has a strongly astringent taste. It burns to a much paler colour, and makes no effervescence with aqua fortis. These are the characters by which this is distinguished from all the other red earths. It is dug in many parts of England, and is sent to London in great quantities. *Hill*'s Hist. of Foss. p. 57.

SIL *atticum* is the purple ochre, called of later times *almagra*. See the articcle ALMAGRA.

SIL *marmorosum* is also a substance in some degree known in the world at this time. It sometimes falls into the hands of our painters who call it Indian stone red, but it has many other valuable qualities extremely worth enquiring into. It is the hardest and driest of all the ochres, and while in the stratum appears absolutely stony, forming thin, flat, regular strata, and is so hard that it is not to be dug without the pick-ax; it is also of an obscurely and irregular laminated structure, and naturally breaks into flat pieces. It is of a fine purplish red, and very heavy, and contains a multitude of fragments of a fine lead ore which are bright and bluish, and make a very pretty appearance, and beside these has always among it a small quantity of pure native cinnabar; both these substances are so nicely mixed with it, that it is scarce possible to break off a piece of an inch square from any part of the strata, that has not more or less of both in it. It is of a dusty surface, and rough to the touch, and adheres very firmly to the tongue, and stains the hands. It is of a very austere and astringent taste, and makes no effervescence with acids. There are considerable strata of it on the borders of China, and it is much used as a paint in the East-Indies. There is some of it at times brought over to us, but not enough to make it a regularly marketable commodity. Beside its use as a paint, it is worth enquiring into an account of the cinnabar it contains; three ounces of it having yielded, on trial, two drams and a scruple of pure quicksilver. *Hill*'s Hist. of Foss. p. 62.

SILACH, a word used by medical authors for a disorder of the eye-lid, consisting in a preternatural thickness of it, or a swelling without inflammation.

SILATUM, a word used by the antient Romans to express a morning's draught of wine. This was usually of a wine medicated with the plant sili, or seseli, and thence had its name. It has always been the custom to medicate the morning draughts of any strong liquor; we do it with wormwood, or the common bitter tincture, the Indians with ginger.

SILAUM, in botany, a name used by some authors for the *saxifraga pratensis*, or common meadow-saxifrage. *J. Bauhin.* Vol. 3. p. 170.

SILENE, in botany, the name of a genus of plants, the characters of which are these. The perianthium is oblong, smooth, and clavated, and consists of one leaf, divided into five segments at the edge. The flower consists of five petals: the ungues of these are as long as the tube of the cup, and their extremities form a limb, which lies flat and expanded: the apices of all the petals are obtuse and marginated. The nectarium is composed of certain denticuli, two of which are inserted near the base of every petal. The stamina are ten subulated filaments, inserted into the ungues of the flower. The antheræ are oblong. The germen of the pistil is cylindric. The styles are either three or five, and are of the length of the stamina, or somewhat more. The stigmata are always bent against the sun. The fruit is the germen enlarged, and divided into as many cells as there were styles: these contain numerous kidney-shaped seeds. Dillenius, in the Hortus Elthamensis, has described these plants under the name *viscago*. *Linnæi* Gen. Plant. p. 197. *Dillen.* Hort. Elth. p. 309.

SILER, in botany, a name given by the Latin writers of the later ages to the plant called by others *seseli*, an umbelliferous herb, growing in mountainous places.

The antient Roman authors, however, mean a very different thing by the word *siler*, a shrub growing in watery places, and having twigs very ductile and tough, and fit for basket-work, or any other use of that kind. The poets have often mentioned it, and always with the epithets of *molle* and *lentum*, soft and tough.

Nothing can be more obvious, than that the *siler* of the later authors is a plant wholly different from this; and it is very properly that some have denominated the umbelliferous plant *siler montanum*, to distinguish it from the shrub-*siler*, which only grows about waters.

Some of the old scholiasts and interpreters of the Roman authors have told us that the *siler*, mentioned by them, is the cyperus; but this must be a mistake. For though this plant grows in watery places, and has considerable tough stalks; yet it is not a shrub, but an herbaceous plant, and is remarkably harsh, and of all plants least deserves the epithet *molle*, which the antients bestowed on their *siler*.

Some have supposed it to be the willow; but this cannot be true: for the willow and *siler* are continually named together, by the same authors, as different plants. The willow, alder and *siler*, being the three shrubs generally mentioned together, as the shrubs that grow about the banks of rivers; the osier is a kind of willow, very frequent at the sides of rivers, and has all the qualities attributed to the *siler* by the antients. It has been supposed by some that this cannot be their *siler*, because as it is a kind of willow, they would have called it by the common name, *salix*; but our own example may plead against this, for we know it to be of the willow-kind, yet we call it by another name: osier is more different in sound from willow, than *siler* from salix, and probably both one and the other signify the same plant.

The error of confounding so different a plant as the *seseli* with this shrub, arises from the unhappy custom of abbreviation, so common among the old Greeks; instead of *seseli* they wrote the word sometimes only *seli*, and *sile*, thence it was easy for people, less acquainted with botanical distinctions, to add an *r* at the end, to reduce the word, which they did not know, to one that they did; and thus grew *siler* as a name for *seseli*. Hippocrates calls the seseli *sili*; and Pliny both *sili* and *seli*. See the article SILI.

SILESIACA-*terra*. See the article TERRA-*silesiaca*.

SILEX, *flint*, in natural history, the name of a genus of semipellucid stones, the matter of which is a crystal, debased by an admixture of a peculiar and appropriated earth, which is of a blackish grey; always free from veins, but, according to the different quantity and disposition of the earth in its composition, subject to clouds of a darker or paler colour, and naturally invested with a thin whitish crust.

Naturalists, in general, have accounted various species of *flint*, but erroneously; nature has established it into a genus of itself, and allowed no other species than one, which is ever composed of the same matter, and differs only in the proportions of its admixture. When crystalline matter is debased by earths of other colours, or clouded and veined, it ceases to be *flint*, and becomes the pebble, the agate, or the onyx; and the not attending to this distinction, has made many describe these variously-coloured bodies twice over: once under the name of *coloured flints*, and a second time under that of *English agates*, &c.

The characters of genuine *flint* are, that it is a stone of an extremely fine and even texture; of a very uncertain surface, sometimes rough, sometimes smooth; of a colour always, in some degree, between blackish and whitish, unless accidentally tinged, as all other fossils are subject to be; very readily giving fire with steel; not fermenting with acids. *Hill's* Hist. of Fossils, p. 508. See the article FLINT.

SILI, in botany, a name given by the old Greeks to a plant called also *seseli*. Hippocrates always calls this *sili* and *sile*, and Pliny uses the same words as some of its names.

This however is not the only meaning of the word, for the epithet *cyprium* being added to it, it signified a very different plant, namely, the ricinus; and the letter *r* being added to the end, and the word written *siler*, it became the name of the osier, as well as of the seseli. This has occasioned great errors about the meaning of the antients, some misunderstanding them as speaking of the osier, when they are describing the virtues of the seseli.

SILICERNIUM, among the Romans, a funeral supper, which is otherwise called *exequium*. *Pitisc.* in voc. See the article EXEQUIUM.

SILILICON, in botany, a name given by some of the old Latin writers to the carob-tree, or *siliqua dulcis*. The Latins borrowed this name from the Greek *xyloglycon*, ξυλογλυκον, the sweet, or sweet-fruited tree. Isidore mispels the word *sililicon*, and making it only *silicon*, supposes it to be a barbarous way of spelling the word *siliqua*; but the evident derivation of the genuine word from the Greek shews his error, both as to the word itself, and the origin of it.

The Latins called this tree *siliqua*, because its fruit was in pods, and the Greeks *ceratium*, κεράτιον, because its pods were bent so, as to resemble horns; but the names *xyloglycon*, and its derivative, *sililicon*, were wholly different from these. The same Isidore observes, that the expressed juice of the fruit of this *silicon* is the drug called *acacia* in the shops; but in this he is guilty of a very great error, the fruit of the *silicon* being esculent, and the acacia a very powerful astringent.

What has led him into this error, has been an observation of the Glossaries on Avisenna, and the other Arabian physicians. These authors have called by the same name, *charub*, or *charnub*, both the carob, or *sililicon*, and the acacia, only distinguishing them by proper epithets. Isidore found in their Glossaries, that charnub was the *siliqua*, or carob-tree, and that the juice of the pods of charnub was acacia; he therefore not observing that there were two charnubs, gave to the latter the properties of the former, and so made the styptic and astringent drug the juice of an esculent plant.

SILICULA, in botany, a name given by some authors to fœnugreek. *Ger.* Emac. Ind. 2.

SILIQUA, (*Cycl.*) in botany, the name of a genus of trees, the characters of which are these. The flower is of the apetalous kind, being composed only of a number of stamina, which arise from the segments of the cup, the middle of which is occupied by a pistil, which finally becomes a flatted

flatted pod of a fleshy substance, and containing flat and roundish seeds.

The species of *siliqua*, enumerated by Mr. Tournefort, are these: 1. The common *siliqua*, called the *eatable siliqua*, or carouge. 2. The esculent *siliqua* with shorter pods. 3. The esculent *siliqua* with various pods. 4. The wild carouge, or not esculent *siliqua*. *Tourn.* Inst. p. 578.

SILIQUA, κεράτιον, among the antients, the third part of an obolus, or, what comes to the same, the sixth part of a scruple. See the articles OBOLUS and SCRUPLE, *Cycl.*

SILIQUA *nabathæa*. See NABATHÆA *siliqua*.

SILIQUARIUS, among the Romans, an officer who exacted, or raised the toll *siliqua*. *Pitisc.* in voc.

SILIQUASTRUM, *Judas-tree*, in botany, the name of a genus of trees, the characters of which are these. The flower is of the papilionaceous kind; the wings, however, stand over the vexillum, and the carina is composed of two leaves. The pistil arises from the cup, and is surrounded by stamina; this finally becomes a flat membranaceous pod, filled with seeds of a kidney-like form. To this it is to be added, that the leaves stand alternately. See Tab. 1. of Botany, Class 22.

The species of *siliquastrum*, enumerated by Mr. Tournefort, are these: 1. The common *siliquastrum*, or *Judas-tree*. 2. The white-flowered *siliquastrum*. 3. The *siliquastrum* with large pods and pointed leaves. 4. The round-leaved Canada-*siliquastrum*. Tourn. Inst. p. 646.

SILIQUASTRUM was used in the botanical writings of the antients for the name of a podded plant, growing wild in some places of Italy, and in others cultivated for domestic and medicinal uses. Pliny, and many other of the antients, have mentioned this, but they have given such imperfect accounts of it, that they have led their followers into many errors about it. At this distance of time, and with the few lights they have left us, it is not easy to say what this plant of the antients was; but it may be a means of leading the reader out of many errors, to say what it was not.

Many have supposed it to be the *zinziber caninum* of Avisenna, and the *hydropiper* of Dioscorides; but the name *siliquastrum* implying its having pods, is a sufficient refutation of its being this plant, which is the common *persicaria*, or biting arsmart.

Others have thought that the *siliquastrum* was the capsicum, or *Guinea-pepper*, as we call it; but however well this plant may agree with the name, as being podded, it can by no means be the plant, since Pliny describes it as common in Italy, and growing wild, which it is very certain that this plant never did.

Many have supposed it to be the plant we call *piperitis*, or *dittander*; but though Pliny has called this plant *piperitis*, from its hot taste of pepper, yet he plainly shews that it was not our *dittander*: for he afterwards describes that as another sort, saying, that there is another broad-leaved kind, which approached to the nature of iberis, but that the large leaves distinguished it: this is plainly enough our *lepidium*, or *dittander*; and therefore the other *siliquastrum*, originally and properly so called, cannot be that plant. Julius Scaliger observes, that there is a shrub growing in Provence at this time, called *siliquastrum*; he supposes this to be the *siliquastrum* of Pliny: it has leaves resembling those of the olive, and short crooked pods. But we do not find any thing either in Pliny, or any other of the antients, to countenance the opinion of the *siliquastrum* being a shrub.

SILIQUASTRUM, in natural history, the name given by Mr. Lhuyd, and others, to the bony palates of fishes, when found fossile. See the article ICHTHYPERIA.

SILIQUATICUM, among the Romans, a custom or toll paid for merchandise. This the Greeks called *ceratismus*. See the article CERATISMUS.

SILK (*Cycl.*)—Raw *silk*, which is a substance of no remarkable smell or taste, yet contains a surprising quantity of a volatile salt. Fifteen ounces of raw *silk* cut small, and put into a retort, when distilled with a gentle fire, will yield two ounces and two drachms of a dry volatile salt; whereas fifteen ounces of hartshorn, a substance usually supposed to contain more volatile salt than any other substance, except sal armoniac, yields only half an ounce and half a drachm: from the same quantity of *silk* there may also be drawn three ounces and an half of volatile spirit; whereas, from the like quantity of hartshorn, the quantity of spirit exceeds this, being four ounces and a half. But we are to consider, that there requires but a small proportion of volatile salt to be dissolved in phlegm, to make it what they call a volatile spirit; and that upon the whole there is no doubt, but that the *silk* contains greatly the larger portion of salt. The caput mortuum, from this quantity of hartshorn, weighed nine ounces and two drachms; whereas that from the *silk* was only five ounces and five drachms: whence it is plain, that the hartshorn contains greatly more earth in the same quantity, and consequently less active principles.

It has generally been agreed, that the spirit of hartshorn is no other than a phlegm, impregnated with a volatile salt, and an extremely penetrating sulphur: this is proved by the following experiment. If spirit of wine be poured upon spirit of sal armoniac, or spirit of *silk*, there is immediately produced a large quantity of a saline concretion; and when the spirit of *silk* is used, this concretion is manifestly composed of considerably large and separate granules of salt; whereas, in case the spirit of sal armoniac has been used, the concretion is perfectly fine, and of an even texture, and it is not easy to say, at first sight, whether it be saline, or sulphureous: this is what has been called by authors *offa Helmontii.* It is proved, however, to be wholly saline, on the adding water to it, since that readily dissolves it. The sulphur, which is contained in these volatile spirits, manifests itself sufficiently by its smell.

The spirit of raw *silk* rectified with some essential oil, is the medicine commonly known by the name of *guttæ Anglicanæ*, or English drops. Mem. de l'Acad. Par. 1700. See the article DROPS.

Silk being properly an animal fluid hardened by the air, is usually much mended or depraved in its nature and qualities, according to the nourishment the worm receives from a good or bad leaf; a great deal, therefore, depends on the goodness or badness of the spring of the year, in the value of the *silk* produced. A warm spring is best, and it should be moderately moist, not overmuch so, because too great a fall of rain is always found to rot the leaves. Southerly winds also are to be feared, because they burst the worms; and northerly ones, when strong, usually spoil the leaves. All these being destructive, either of the animals themselves, or of their food, very just presages may be formed upon them of the produce of the ensuing year.

When these mischiefs do not happen, but the spring is favourable, the people have little to do but to watch the feeding of the worms, and about Midsummer they are to begin to draw the *silk* from its cocoon, to see what it yields, and judge of its encrease or scarcity, and estimate its goodness and perfections; the principal of which are, that it proves clean, light, and strong.

Great use may be made of these observations, provided the management be good. It requires great care to hatch the eggs, and when hatched, there must be a careful eye over the worms, even to the time of drawing off the *silk*. If the season foretels a scarcity, the business of the prudent manager is to buy up all the old *silk* he can procure, and keep as much of the other as he can, to be employed in the best fabrics, that so they may not be obliged to hazard all the good at the price of the worst: but when the season proves favourable, they collect the new for the best fabrics, and compare it with the old, to see whether it be of a better quality, before they venture to determine their prices.

The goodness of *silk* is best distinguished by its lightness, that being its most essential quality: this every one knows carries a very great profit with it, being bought by weight, and sold by measure, at the first hand, after the collectors. The Organcine *silk* is the best of any made in the country of Piedmont, and two threads are equal in fineness, that is in smoothness, thickness, and length, for the thread of the first twist. For the second, it matters not whether the single thread be strong before the two are joined, unless to see whether the first twist prove well. It is necessary that the *silk* be clean, and it is to be observed, that the straw-coloured is generally the lightest, and the white the heaviest of all. The skains should be even, and all of an equality, which shews that they were wrought together; otherwise we may with justice suspect that it is refuse *silk*, and cannot be equally drawn out and spun, for one thread will be shorter than the other, which is labour and loss.

It will also be requisite to search the bale more than once, and take from out of the parcels a skain to make an essay; for unless it be known by trial what one buys, there is the greatest danger of being cheated in this commodity. To make an estimate, and know the lightness, fix the essay upon one eighth of a portée, or hand of *silk* of a hundred and ten aunes or ells of Lyons in length, and see what it makes of aunes by the eighth part. The skain, which is of eighty threads, must be multiplied by a hundred and ten aunes of Lyons, and from this number must be deducted one eighth; as for example, 110 by 80 makes 8800, the eighth part of which is 1100; and this is the eighth part of a portée, or hand of *silk*. Now to calculate what these 1100 aunes weigh, which is the eighth part of a portée, or of 110 aunes of Lyons, it will be proper to take a skain out of the parcels, which you take from out of the bale which you judge may contain, at least, 1100 aunes, to make the one eighth part of a portée, which portée must be divided on two bobbings, half on each; then fix the two bobbings on the center, or beam, and from thence pass it through the comb hurdissoir, *viz.* 550 from the two bobbings, will make 1100, which will be one eighth part of what you desire to know. This done, you cut off your *silk*, and carry it to put on the hurdissoir; then weigh it, and multiply the weight by eight, it will weigh just as much as a portée of 110 aunes of Lyons, which is the general rule for calculating. When they draw the *silk* out by this means, one may learn to adjust the weight.

There are *silks* of Piedmont which are very light and clean, and are to be preferred before any on the sale: the portée of *silk* of the lightest weighs near twenty four pennyweights, and

and from this it arifes in gravity to twenty five, and twenty fix pennyweights the portée, and fometimes to twenty feven and twenty eight; but even thefe weights may be difpenfed with, provided that the other qualities be good, that is, that it be well wrought, even, and clean. When the *filk* is more than twenty eight pennyweights the portée, it muft always be proportionably cheaper. Philof. Tranfact. N° 252. p. 186.

SILK-*worm*, *bombyx*. This infect confifts of eleven rings, and each of thefe of a great number of other fmaller ones, joined to each other; and the head, which terminates thefe rings, is furnifhed with two jaws, which work and cut the food, not by a perpendicular, but a lateral action. The humours, found in the body of this creature, all feem approaching to the nature of the *filk* which it fpins, for on being rubbed in the hands, they leave a hard or folid cruft behind them. Under the fkin there is always found a mucous rofy-coloured membrane, enveloping the animal, and fuppofed to be the new fkin in which it is to appear, on throwing off the old one. The heart of this creature reaches from the head to the tail, running the whole length of the body: it is indeed rather a feries of many hearts connected together, than one. The motion of fyftole and diaftole is very evident in this whole chain of hearts; and it is an elegant fight to obferve the manner of the vital fluid's paffing from one of them to the other. The ftomach of this animal is as long as the heart, reaching, like it, from one end of the body to the other. This large receptacle for food, and the fudden paffage of it through the animal, are very good reafons for its great voracity.

In the fides of the belly, all about the ventricle, there are depofited a vaft number of veffels, which contain the *filky* juice; thefe run with various windings and meanders to the mouth, and are fo difpofed, that the creatures can difcharge their contents at pleafure at the mouth; and according to the nature of the juices, that they are fupplied with, furnifh different forts of *filk* from them, all the fluid contents of thefe veffels hardening in the air into that fort of thread, that we find the web, or balls of this creature confift of.

Thefe creatures never are offended at any ftench of whatever kind, but they always feel a fouthern wind, and an extremely hot air always makes them fick. *Malpighi* de Bombyce.

Chryfalis of the SILK-*worm*. See the article FEVE.

SILVER (*Cycl.*)—*Silver* works, as fpurs, wrought hilts, &c. are boiled in falt, alum and argol, to give it a whitenefs and clearnefs. *Boyle*'s Works Abr. Vol. I. p. 135.

Silver burnt on a glafs-plate tinges it of a fine yellow or golden colour. *Boyle*'s Works, Vol. I. p. 147. See alfo p. 458. and Vol. II. p. 64.

Chemifts have made frequent attempts to diffolve *filver* in vegetable acids, but with little fuccefs, according to Mr. Marggrave; who fays, that he himfelf, at laft, fucceeded in the attempt.

The chief art required, is to find a proper precipitate of *filver*. Mr. Marggrave's is formed by precipitating a folution of *filver*, in the beft fpirit of nitre, with that falt of urine which he fays is the bafis of phofphorus. See SALT *fufible of urine*.

This precipitate reduced to a fine powder, and digefted in a fand-heat with diftilled vinegar, well concentrated by freezing, will in part be diffolved thereby.

But if this precipitation of the *filver* be made with falt of tartar, and then dried and pulverized, a confiderable quantity of it may be diffolved in diftilled vinegar, in juice of lemons, in Rhenifh wine, and in other vegetable acids. The like may be done with mercury. Mem. de l'Acad. de Berlin, 1741. See MERCURY.

Purified SILVER. The moft commodious and regular manner of purifying *filver* is this: put a large teft, inclofed in an iron ring, into a furnace; when the teft has been red-hot about half an hour, put into it the *filver* to be purified, wrapt up in pieces of cloth or paper, and divided into fmall portions; then fill the orifice of the furnace with burning coals, and blow with a pair of hand-bellows, till the *filver* is in fufion; then add, at feveral times, fome lead, reduced to globules of a determined weight; continue adding lead, and keep the fire in fuch a degree, as is juft fufficient to keep the metal in fufion, and continue thus, till the *filver* is rendered quite pure. This may be partly gueffed, by the before made trial of its degree of impurity on the touchftone, and by the quantity of lead, judged neceffary for the operation, having been confumed; and farther known, by trial of it on a wire thruft into it while in fufion, and the examining what is found adhering to it when it is taken out. When the operation is finifhed, pour water in a fmall ftream on the *filver* to make it grow folid, and taking it out of the teft, clean it from all impurities that may adhere to its furface with a brufh made of fmall brafs wire. *Cramer*'s Art of Affaying, p. 204. 208.

The way of purifying *filver* by means of nitre is this: reduce the *filver* to grains, or fmall thin plates, put it into a crucible, and add one quarter part of nitre, well dried and powdered: put upon this crucible another of a fmaller fize, having a hole as big as a pea in its bottom; lute the joint of the two crucibles, and place them in a wind-furnace; put charcoal about them as high as the rim of the lower crucible, but no higher, then light the fire at top, and encreafe it till the veffels are middlingly red-hot, then with a pair of tongs hold a burning coal directly over the hole in the upper crucible, but at the diftance of one finger; if you fee a fudden clear light produced near and about the coal, together with a crackling noife, this fhews that the fire has the right degree of ftrength; but if this does not appear at all, or but very faintly, the fire muft be encreafed: but if, on the contrary, you hear a violent blaft of air from the hole, and a loud crackling noife, without holding the coal over, the fire is then too fierce, and muft be diminifhed, otherwife you will not only lofe a large quantity of *filver*, but very often the veffels will burft.

When this is perfectly over, encreafe the fire fo far, as to be able to melt *filver* without any addition; then take out the veffels, and when they are cooled break the under one, and you will find the regulus of *filver* at the bottom, and an alkaline fcoria, commonly green, at the top. If the *filver* is not yet thoroughly purified, put it into another crucible, and this open into a wind-furnace, throwing upon it a little nitre, and as foon as it melts, pour it into a mould for ingots; thus will it be purified from every thing but gold. *Cramer*'s Art of Affaying, p. 246.

When any quantity of this metal is contained in iron, it may, according to the rules of affaying, be precipitated from it by fcarification, by the affiftance either of ftrong acid menftrua, or of crude antimony; the latter method is the eafier, and is performed thus: put one centner of the iron reduced to very fine filings, and two centners of crude antimony, into a fmall crucible, clofe it with a tile, and fet it in a ftrong fire, that it may melt; when it has been in a perfect ftate of fufion for fix or eight minutes, take it out, and let it cool, break the crucible, and you will find a mafs, compofed of fcoria at top, and a regulus underneath; throw away the fcoria, and powder the regulus, mix it with twelve centners of granulated lead, and fcorify it in a continual, but not over-ftrong fire, till the lead is feen covered all over its furface with fcoriæ, then take it out, and pour the mafs into a mould: the regulus fhould now be tough, and of a light lead-colour, both within and without; if it be blackifh and brittle, it muft be returned into the teft, and fcorified again, and when brought to its proper ftate, and the antimony all confumed, let it be put into the coppel; and when the bead of *filver* is produced pure, fubtract from its weight the before known quantity of the *filver* contained in the lead ufed in the procefs, and the reft is the weight of the filver obtained from the iron. *Cramer*'s Art of Affaying, p. 223.

SILVER, in medicine, is mightily cried up for its virtues by chemical writers; accordingly, they have endeavoured to introduce a train of lunar medicines, as they call them, fuch as *argentum potabile*, *diaphoreticum lunare*, *bezoardium lunare*, and fifty others, as pompous as infignificant.

The only preparations of *filver*, which keep up their credit in the fhops, are the lunar cryftals, and the lunar cauftic, called *lapis infernalis*; both which are violent cauftics, eating away the flefh, and even the bones, they are applied to. See CAUSTIC.

Inflammable SILVER, a chemical preparation of the lapis infernalis made by a fmall heat. The procefs is this: take an ignited piece of Dutch turf, after it ceafes to fmoak, place it with its upper flat furface parallel to the horizon, make a little cavity in the middle, and therein put a drachm of dry lapis infernalis; it will immediately melt and glow, and finally it will take flame, and hifs and fhine like nitre: after the flame ceafes, pure *filver* will be found in the hollow, as much in quantity as was ufed in the making fo much lapis infernalis.

This curious experiment fhews the phyfical manner in which acids do but fuperficially adhere to *filver*; and the manner wherein acids operate, when united to metals, while furrounding their metallic mafs, they arm the ponderous principles thereof with fpiculæ: it fhews alfo the immutability of *filver* diffolved in an acid, and the various ways in which it may be concealed, yet ftill have its action: it alfo fhews the difference of potable *filver*, while exifting in a faline form, by means of an adhering acid, from that potable *filver* of the adepts, where the principles of *filver* are fuppofed converted into a fluid, that will mix with the juices of the body, and cannot be reduced to *filver* again; but the great thing to be here obferved, is, that the acid fpirit of nitre, adhering in a folid mafs of *filver*, is in this ftate as inflammable, on coming in contact with an ignited combuftible body, as crude nitre itfelf: this feems to happen with *filver* alone, which is unchangeable with fpirit of nitre. Hence alfo we fee one way, by which *filver* may be obtained pure from other adhering matters, by bare burning: the acid here acts neither upon the mercurial part of the *filver*, nor on its fixing fulphur. *Boerh.* Chem. Part 2. p. 297.

SILVER-*ores*. Some of the *ores* of *filver* are rendered very refractory in the working, by means of a mixture of unmetallic earths, from which no art can wafh them clean. The

method to procure the *silver* from these by an assay is this: powder the *ore* very fine, and to a docimastical centner of it add an equal quantity of glass of lead, mix these thoroughly together; the glass of lead must, for this purpose, be reduced to as fine a powder as the *ore*; put this powder, when well mixed, into a test, with twelve centners of granulated lead, and put the test under a muffel in a furnace, make a strong fire, till the lead boils well; when it is in this state, diminish the fire a little, and keep it in this weaker state for some time, then encrease it again to a great strength, till the lead is reduced to scoriæ, and the *silver* is seen pure in the test; or else when the scorification is perfected, take out the matter together, and putting it into a coppel with more granulated lead, separate the *silver* in a bead. Sometimes a refractory *ore* of this kind cannot be thus sufficiently dissolved, but a mass, which has the clammyness of pitch, swims upon the surface of the regulus, and upon the scoriæ that are in part subdued: in this case, diminish the fire, and touch this clammy mass with a small cold iron hook, to which it will immediately stick; take it all carefully off, reduce it to fine powder, and mixing it with more glass of lead in powder, put it back into the test, then continue the scorification till it is perfected: but always observe that the scoriæ of these refractory *ores* must be examined, to see if some of the regulus does not remain among them, for sometimes the scoriæ, by their clammyness, will retain part of the metal; if this appears to be the case, powder the scoriæ very fine, and the metal will be discovered and separated, as it cannot be reduced to a fine powder. *Cramer's* Art of Assaying, p. 218.

The method of precipitating *silver* out of an easily fusible *ore* is this: pound the *ore* very fine in an iron mortar, and for an assay weigh one docimastical centner of it, and eight centners of granulated lead; pour into a new test about half the lead, stir it about with a finger, and spread it over the cavity of the test; put upon this lead the pounded *ore*, and then cover it with the remainder of the lead; put the test, thus loaded, under the muffle of an assay-furnace, and in the hinder part of it make the fire, and encrease it to a considerably high degree. The *ore* will soon be raised out of the melted lead, and swim upon it; a little after it will grow clammy, melt, and be thrown toward the border of the test; then the surface of the lead will appear clear in the middle of the test, and will smoak and boil; the fire must now be made a little less, till the boiling ceases, for a quarter of an hour, and then made violent again, and the surface of the lead will then diminish by degrees, and be covered with a mass of scoriæ. At this time have at hand an iron hook ready heated, and with this stir all the matter from the sides into the middle of the test; if the matter, adhering to the hook from the stirring, melts quickly again, and the extremity of the hook, when cold, is found covered with a shining crust, the scorification is perfected; but if the scoriæ feel clammy while stirred, and adhere in quantity to the hook, and are of a rough surface, the scorification is not perfect, but the matter adhering to the hook must be struck off with a hammer, and beat to powder, and returned into the test, and the fire continued till the scorification is perfected; then take out the test, and pour the whole contents into a mould, heated and greased. This is the first process, and this usually takes up three quarters of an hour: the *silver* is now in form of a regulus, and must be separated by the coppel in the usual way. *Cramer's* Art of Assaying, p. 205. See the article REGULUS.

Mundic is a very common thing in *silver-ores*, especially in the less rich ones, and gives great trouble in working the metal. The method of separating the *silver* from an *ore*, rendered refractory by this admixture, is thus: break the *ore* into a rough powder, and put a centner of it into a test for an assay; put upon this another test, by way of a cover, and put it under the muffle in a furnace; when the muffle is near red-hot, encrease the fire by degrees, there will be a crackling noise, which being ended, take away the upper test, for when the vessels have been red-hot about a minute, the *ore* ceases to split; leave the *ore* under the muffle, till the arsenic and sulphur are in a great measure evaporated, which will be known by the cessation of the smoak from the *ore*, and of the smell of garlick, or the acid; then take out the test, and leave it in a place not too cold, that it may cool leisurely of itself; take the roasted *ore* clean out of the test, powder it very fine, and mix it with an equal quantity of glass of lead in fine powder; and finally, scorify the mass in the same, or in a new test, if that was cracked, till the *silver* appear in form of a bright bead in the middle, after it has stood a minute or two; after this take it out of the fire, and when cold take out and weigh the pure *silver*. *Cramer's* Art of Assaying, p. 221.

Alonso Barba tells us, that the original method of extracting *silver* from the *ore*, in the mines of Potosi, was only by quicksilver, but this was very difficult in many cases. Those *ores* which partake of copperas, which are very numerous there, will not bear quicksilver, but consume and scatter it, breaking its particles, and rendering them unfit for the purposes they were intended for, of taking up the *silver* contained in the *ore*. Burning the *ore* was another method heretofore used with too little caution, and great losses were sustained by it. The grinding the *ore* is always proper, and the finer it is ground, the better it will always succeed. Alonso Barba also greatly recommends boiling the *ores*, in which the quicksilver is used, as of great advantage. The burning of *ores* is of no service, but to render the stony matter more friable; but when there is marcasite among the *ore*, this is never done without loss, and that often very great. *Alonso Barba* de Metall.

The largest piece of *silver-ore* we have account of any where, is at this time preserved in the king of Denmark's Museum of Curiosities at Copenhagen; this was dug in the mines of Norway, and weighs five hundred and sixty pounds. It is five feet six inches long, and measures four feet about: it is valued at five thousand crowns. There is in the same place another also, which was dug in the same mine, valued at three thousand two hundred and seventy crowns. These are both so very rich, that they seem at least three parts *silver*, and the metal appears in very elegant forms in them, and rises up out of their surface in form of small trees and bushes. There are also several pieces of pure native, or virgin *silver* there, all of which represent trees or plants.

SILVER-*pill*, a chemical preparation of *silver*, formerly highly commended as a remedy for dropsies, and in many other diseases.

The method of making it is this: dissolve an ounce of pure nitre in distilled water, then dissolve an ounce of crystals of *silver* made in the common way, with pure *silver* and aqua fortis, in three times the weight of water, so that the solution may be perfectly limpid; mix the two solutions together, they will become a clear homogene liquor, evaporate this to a pellicle, and crystals resembling nitre will shoot; pour off the remaining nitre as before, and the remaining nitre will shoot with the *silver*, in form of crystals, again, upon a second evaporation: let these crystals be dried upon a paper, and then placed in a glass vessel in a very gentle heat, enough to make them smoak, but not run, stir it with a piece of glass all the time, and keep it over the fire, till no more fumes arise; thus the acid spirits will be driven off, and the *silver* remain of a very bitter taste, and purging quality. It must be kept in a dry close vessel. This discovery has been made to serve to many other purposes, beside its uses in medicine, and has furnished the dishonest pretenders to alchemy with one of their most cunning methods of deceit. They have been able, by this means, to conceal *silver* in nitre, and that in a very large proportion, as in one tenth part of the whole quantity; and this nitre being projected in an equal quantity on melted lead, gives an increase of one tenth part in *silver*, which remaining upon the test, will deceive the ignorant, as if a tenth part of the lead were converted into pure *silver*. People who are upon their guard may, however, discover the cheat, by dissolving the pretended nitre in ten times its weight of water, and putting a polished plate of copper into the solution; for every particle of the *silver* will then be precipitated out of the liquor upon the copper, and to the bottom of the vessel. *Boerh.* Chem. Part 2. p. 296.

The medicinal use is this: the dried mass, consisting of the salts of *silver* and nitre, is to be reduced to a fine powder; this powder applied to ulcers, acts in the manner of the lapis infernalis, or *silver*-caustic, only much milder: but for internal use, the quantity of two grains of it is to be ground to a fine powder, with six grains of loaf-sugar, in a glass mortar, this is to be then mixed with ten grains of the crumb of bread, and formed into nine *pills*: these are to be taken by a grown person upon an empty stomach, drinking after them four or six ounces of hot water, sweetened with honey. It purges gently, and brings away a liquid matter like water, often unperceived by the patient. It is said to kill worms, and perform great things in many obstinate ulcerous disorders. It purges without griping, but it must not be used too freely, nor in too large a dose, for it always proves weakening, and in some degree corrosive on the stomach; but this inconvenience is greatly alleviated by rob of juniper. *Boerh.* Chem. Part 2. p. 297.

SILVERING (*Cycl.*)—To *silver* brass: fine *silver* is dissolved in aqua fortis in a broad bottomed vessel of glass, or glazed earth, and the aqua fortis being afterwards evaporated, water is poured upon the remaining calx. This water must also be evaporated, and the operation repeated as often as there is occasion; the fire being increased towards the latter end, so as to leave a perfectly dry and white calx, which will be thus tolerably freed from the aqua fortis. Of this calx take one part, and an equal measure, not weight, of common salt, and of the crystals of tartar, and mix them together into a fine powder; then having first plunged the scowered brass into fair water, rub some of the powder upon it with your wet fingers, till the cavities of its surface be sufficiently filled therewith. Lastly, wash the metal well in water, and give it a gloss by rubbing it hard with a dry cloth.

This waſhing, Mr. Boyle obſerves, is expeditious, cheap, requires no quickſilver, and may be made to laſt ſome years, and is eaſily renewable, when it begins to wear. See his Works Abr. Vol. I. p. 151.

SILVERING *of glaſſes*. An excellent method of turning ſpherical, and other glaſſes, into ſpeculums by *ſilvering*, is this: take half an ounce of pure lead, and melt it into a maſs with the ſame quantity of fine tin, then immediately add half an ounce of biſmuth, and carefully ſkim off the droſs; remove the ladle from the fire, and before the matter is cold, add to it five ounces of pure quickſilver, ſtir the whole together, and then put the fluid amalgam into a clean glaſs.

When this is to be uſed for foiling, or *ſilvering*, let it be ſtrained through a linnen rag, and then gently pour ſome ounces of it into the glaſs intended to be foiled, by means of a paper funnel, reaching almoſt to the bottom, to prevent its flying up to the ſides; then dexterouſly inclining the glaſs every way, endeavour thus to faſten the foil. When this is done, let the glaſs reſt for ſome hours, then repeat the operation, till at length the whole fluid maſs is evenly ſpread and fixed over the whole internal ſurface; then let the ſuperfluous amalgam be poured out, and the outſide of the glaſs poliſhed. This is the method by which glaſs ſpheres are made to look as if full of quickſilver, and deſerves to be tried on the common looking-glaſſes, as having many advantages over the uſual way of *ſilvering* them. *Shaw*'s Lectures, p. 428.

SILURUS, in zoology, the name of a very large fiſh, commonly called in Engliſh the *ſheat-fiſh*.

It is caught in the Viſtula, and other large rivers, and grows to an immenſe ſize, ſome having been caught of more than an hundred weight, and of fixteen feet long, and ſometimes conſiderably larger than that. It reſembles the eel in colour, but the belly is variegated with black, white, and duſky ſpots. The body is without ſcales, and is covered with a mucous ſubſtance. The head is flat, ſhort and broad, the opening of the mouth extremely large. The body down to the fundament is thick and cylindric, but the bottom of the belly is flat, and from the anus to the tail it is broader and flat. Its eyes are large, and have two antennæ, or ſlender excreſcences before them; and four beards hang from the lower jaw. The gills are four on a ſide. It has only one ſmall fin upon the back, and the tail is not forked. Its fleſh is much eſteemed for food, and is dreſſed for the table as the eel. It is a very voracious fiſh, and much dreaded whenever it comes among the ſmaller fry.

Geſner mentions two other ſpecies of it, one flatted toward the tail, and the other of a mixed green and yellow colour, and having two beards on the upper jaw, and three on the under: he only calls theſe *ſiluri ſecunda*, and *tertia ſpecies*. *Willughby*, Hiſt. Piſc. p. 128.

The name is of Grecian origin, and is derived from the words σειν, to move or ſhake, and ουρα, a tail. It is given to this fiſh, from its remarkable quality of being almoſt continually moving its tail in the water.

SILURUS is alſo a name given by ſome authors to the ſturgeon, called by others *accipenſer*, but by the generality of writers *ſturio*. *Salvian*, de Aquat. See the article STURIO.

SIMARONA, a name given by the Spaniards in America to a ſpecies of vanilla, called alſo *baſtard-vanilla*. The pods of this kind are every way ſmaller than thoſe of the true kind, and have very little liquor, or pulp in them when broken, and contain very few ſeeds. Theſe are greatly inferior to the true kind, having ſcarce any ſmell. It is not yet certainly known, whether this ſpecies be the fruit of a different kind of vanilla-plant from the common, or whether it be the ſame fruit gathered at a different ſeaſon, or from a plant growing in a different ſoil. See the article VANILLA.

SIMAROUBA. The bark of this plant is very ſucceſsful in the cure of dyſenteries, as Mr. Juſſieu aſſures us from his experience. It is a thick yellow bark, of an aſtringent bitteriſh taſte, and reſembling, as it is ſaid, the *macer* of the antients. It was firſt brought into Europe from America, in 1713; but of the tree, which produces it, we have no certain account.

This medicine is more ſucceſsful in decoctions than in ſubſtance. The doſe is about the third part of a quart of decoction, having two drachms of the bark in it. See Mem. de l'Acad. des Scienc. Anno 1729.

SIMARUM *muſculus*, in anatomy, a name given by ſome of the old writers to a muſcle, called by the moderns the *ſerratus magnus*. See SERRATUS.

SIMBALATH, in the materia medica, a name given by Avifenna and others to the ſpikenard, or *nardus Indica*.

The exact interpretation of the word is *ſpicigera*, and Avifenna, under this general name, diſtinguiſhes it into ſeveral kinds; the firſt he calls *alnardin*, or *nardin*. It has been ſuppoſed by ſome that he means the Indian *ſpikenard* by this word, but, on the contrary, it appears plainly that he means the Celtic *nard*; he calls it the *nardus Romani orbis*, and ſays that it is of European growth. After this he mentions the Aſiatic *nards* of ſeveral kinds, which are only the Indian *ſpikenard*, growing in different places, and ſuch as uſed to be brought thence in different degrees of perfection. See the article NARDUS.

SIMIA, the *ape* or *monkey*, is made by Linnæus a diſtinct genus of animals, the character of which is, that the creatures of this kind have teeth, have feet compoſed of five toes, and made for climbing, and have their paps on the breaſt. *Linnæi* Syſtem Nat. p. 34.

This genus comprehends the *monkey*, *ape*, and *baboon* claſſes, but more regularly, the word *ſimia* is the name of that kind only which has no tail, the tailed ones being, in diſtinction, called *cercopitheci*, or *tailed monkeys*.

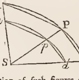
The proper name of the *ſimia*, in Engliſh, is *ape*, and thoſe which have tails, are diſtinguiſhed by the name *monkey*. See CERCOPITHECUS.

There are many ſpecies of *apes*, and even many more than were ſuppoſed by authors; America affording us frequent inſtances of ſuch as have not been deſcribed in any book. *Ray*'s Syn. Quad. p. 149.

SIMIA *marina*, the *ſea-ape*, a name uſed by Bellonius, and ſome other authors, for the fiſh called *vulpes marina*, a kind of ſhark, remarkable for its long tail, from which probably it had both one and the other of theſe names. *Willughby*, Hiſt. Piſc. p. 54.

SIMICON, in antiquity, a muſical inſtrument of the ſtringed-kind, with thirty-five ſtrings. Mem. de l'Acad. Inſcript. Vol. 5. p. 168.

SIMILAR (*Cycl.*)—SIMILAR *curves*, in geometry. The *ſimilarity* of curvilinear figures may be derived from that of rectilinear figures, that are always *ſimilarly* deſcribed in them; or, we may comprehend all ſorts of *ſimilar* figures, planes, or ſolids, in this general definition: figures are *ſimilar*, when they may be ſuppoſed to be placed in ſuch a manner, that any right line being drawn from a determined point to the terms that bound them, the parts of the right line, intercepted betwixt that point and thoſe terms, are always in one conſtant ratio to each other. Thus the figures ASD, *a* S *d*, are *ſimilar*; when any line S P being drawn always from the ſame point S, meeting A D in P, and *a d* in *p*, the ratio of S P to *ſp* is invariable. It is manifeſt, that the rectilinear inſcribed figures *a p d* S, A P D S, are *ſimilar* in this caſe, according to the definition of ſuch figures given in Euclid's Elements, Book 6. See *Mac Laur.* Flux. Art. 122.



When the *ſimilar* figures are in the ſituation here deſcribed, they are alſo *ſimilarly* ſituated, and all their homologous lines are either placed upon one another, or parallel.

SIMILAR *diameters* of two conic ſections. When the diameters in two conic ſections make the ſame angles with their ordinates, they are ſometimes ſaid to be *ſimilar*.

SIMILAR *ſolids*, ſuch as are contained under equal numbers of *ſimilar* planes, alike ſituated.

SIMILAR *bodies*, in natural philoſophy, ſuch as have their particles of the ſame kind or nature one with another.

SIMILAR *animals*. We have a treatiſe by Dr. Martin, wherein he treats of the laws and proportions of the motions and forces of the ſolids and fluids of animals, of however different magnitudes, which are ſuppoſed of *ſimilar* make and conſtitution. See Tractat. de Similibus animalibus.

SIMON, in zoology, a name by which ſome authors have called the dolphin. It is affirmed that this fiſh loves the name, and will come to a perſon who calls him by it; but this, though recorded by authors of credit, meets with no faith among the judicious readers. *Ray*'s Ichthyography, p. 31.

SIMPLE (*Cycl.*)—SIMPLE *leaf*, among botaniſts. See the article LEAF.

SIMPLE, or *ſingle eccentricity*. See ECCENTRICITY, *Cycl.*

SIMPLE *problem*, in mathematics. See LINEAR *problem*, *Cycl.*

SIMPLE *roots*. See FIBROSE *roots*.

SIMPLE *waters*, in diſtillery. See WATERS.

SIMPULUM, among the Romans, a veſſel with a long handle, and made like a cruet. It was uſed in ſacrifices and libations, for taking a very little wine at a time. *Pitiſc.* Lex. Antiq. in voc.

SIMULACRUM, among the Romans. See the articles IDOL and IDOLATRY, *Cycl.*

SIMUS, in zoology, the name uſed by ſome authors for the *naſus*, or *naſe*, a fiſh common in the large rivers in Germany, and ſomewhat reſembling our chub, and in ſome reſpects our common rudd. *Geſner*, de Piſc. p. 213. See the article NASUS.

SINAPI, *muſtard*, in botany, the name of a genus of plants, the characters of which are theſe. The flower is compoſed of four leaves, and is of the cruciform-kind. The piſtil ariſes from the cup, and finally becomes a long pod, divided by an intermediate membrane into two cells, and containing roundiſh ſeeds; the pod alſo uſually terminates in a fungoſe horn, which has ſome ſeeds in it. To this it is to be added, that theſe plants have all a hot, acrid, and biting taſte.

The species of *sinapi*, enumerated by Mr. Tournefort, are these. 1. The turnep-leaved *mustard*. 2. The white *mustard* with hairy pods, and red and white seeds. 3. The early wild *mustard* with black seeds, called by many *charlock*. 4. The early black-seeded field-*mustard*, or charlock, with undivided leaves. 5. The rocket-leaved *mustard*. 6. The Spanish *mustard* with lobated leaves, and sulphur-coloured flowers. 7. The cress-leaved Spanish *mustard*. 8. The small radish-leaved Spanish *mustard*. 9. The dwarf white Spanish *mustard*. 10. The largest Indian lettuce-leaved *mustard*. 11. The large Indian lettuce-leaved *mustard* with narrower leaves. *Tourn.* Inst. p. 227. See MUSTARD.

SINAPI *Persicum*, *Persian mustard*, a name by which some botanical authors have called the *thlaspi*, or treacle-mustard. *Ger.* Emac. Ind. 2.

SINAPISIS, a word used by some writers as a name for *Armenian bole*. *Cast.* Lex. Med. in voc.

SINAPISTRUM, in botany, the name of a genus of plants, the characters of which are these. The flower consists of four leaves, disposed in the form of a cross. The pistil arises from the cup, and at length becomes a long cylindric bivalve pod, usually containing roundish seeds.

The species of *sinapistrum*, enumerated by Mr. Tournefort, are these. 1. The more prickly seven-leaved Egyptian *sinapistrum* with flesh-coloured flowers. 2. The lesser, not thorny, five-leaved Indian *sinapistrum* with flesh-coloured flowers. 3. The trifoliate, not thorny, Indian *sinapistrum* with flesh-coloured flowers. 4. The shrubby trefoil American *sinapistrum* with the taste of cresses. 5. The trifoliate red-flowered Portugal *sinapistrum* with horned pods. *Tourn.* Inst. p. 231.

SINASBARIUM, in botany, a name given by some authors to the *sysimbrium*, or water-mint, common in all our ditches and watery places. *Ger.* Emac. Ind. 2.

SINE (*Cycl.*)—SINE *of incidence*, in catoptrics and dioptrics, is used for the *sine* of the angle of incidence. See the article INCIDENCE, *Cycl.*

SINE *of reflection*, in catoptrics, is used for the *sine* of the angle of reflection. See REFLECION, *Cycl.*

SINE *of refraction*, in dioptrics, is used for the *sine* of the angle of refraction. See REFRACTION, *Cycl.*

SINE *assensu capituli*, in law, a writ that lies where a bishop, dean, prebendary, or master of an hospital, aliens the lands holden in right of his bishoprick, deanery, house, &c. without the assent of the chapter or fraternity; in which case his successor shall have this writ. F. N. B. 195. *Blount*, *Cowel.*

SINEW (*Cycl.*)—SINEW, in the manege. To *unsinew* a horse, called in French *enerver*, is to cut the two tendons on the side of the head, about five inches under the eyes; which two join in one at the tip, or end of the nose, in order to perform its motion. This tendon, at the tip of the nose, is likewise cut. We *unsinew*, in order to dry the head, and make it smaller.

SINEW-*shrunk*, is said of a horse that is over-rid, and so worn down with fatigue, that he becomes gaunt-bellied, through a stiffness and contraction of the two *sinews* that are under his belly.

SINEW-*sprung*, is a violent attaint, or over-reach, in which a horse strikes the toe of his hinder feet against the *sinew* of the fore legs.

SINF, in the materia medica of the antients, a word used to express the same as *agallochum*, or lignum aloes.

The Arabians formed an adjective of this word, and called the yellowish lignum aloes *sinficum*, and the blackish *indicum*. Not that the sinficum came from any other place, or that the Indicum was given as the name of the country, but that the colours only were expressed by these epithets; *indicum* being with the antients as a common word to express black by. The only species of myrobalan they had of a black colour, was called the *Indian myrobalan*; not for its being peculiarly the produce of that country, but because of its being of the colour they expressed by that word.

SINGERS, in the Jewish antiquities. See CHANTERS.

SINGLE (*Cycl.*)—SINGLE *cast*, in husbandry, a term used by the farmers for that sort of sowing, that disperses the necessary quantity of corn at one bout. *Plot*'s Oxfordshire, p. 251.

SINGULATOR, among the Romans, a horseman who rode with one horse only. *Pitisc.* in voc.

SINKING, or ABSORPTIONS *of the earth.* Kircher has written very largely on this subject, and antient and modern histories agree in relating many such facts. The *absorptions* themselves are indeed too common, and are the effects of earthquakes, subterranean fires, and many other accidents of the macrocosm; but there are much fewer instances of the restoring the places thus *absorbed*, and there are but few of those instances, which are recorded of it, that deserve credit, though some are unquestionable.

Pliny tells us, that in his own time the mountain Cymbotus, with the town of Eurites, which stood on its side, were wholly *absorbed* into the earth, so that not the least trace of either remained; and he records the like fate of the city Tantalis in Magnesia, and after it of the mountain Sypelus, both thus *absorbed* by a violent opening of the earth. Galanis and Garnatus, towns once famous in Phœnicia, are recorded to have met the same fate; and the vast promontory, called Phlegium, in Æthiopia, after a violent earthquake in the night-time, was not to be seen in the morning, the whole having disappeared, and the earth closed over it. These and many other histories, attested by the authors of greatest credit among the antients, abundantly prove the fact in the earlier ages; and there have not been wanting too many instances of more modern date. *Kircher*'s Mund. Subter. p. 77.

The mountain Picus, in one of the Molucca isles, was so lofty, that it appeared at great distances as an immense column reared erect in the air, and served as a land-mark to sailors; an earthquake in this island destroyed it; at one instant the whole mountain was *absorbed* into the bowels of the earth, and no mark of its place remained but a vast lake of water, exactly answering to the shape of the base of the mountain. A like accident, but of a more terrible kind, happened in China, in the year 1556, when a whole province of the mountainous parts of that kingdom was in one moment *absorbed* into the earth, and all the towns buried, the whole number of the inhabitants *sinking* with it, and an immense lake of water remaining in its place to this time. Of much later date is the destruction of a city in the confines of Swisserland; but this, though generally said to have been swallowed up into the earth, was not properly an *absorption*; for the whole city was buried by the fall of a mountain upon it.

The burning mountains, Vesuvius and Strongylus, both once very high, have in length of time lost half their height, the upper part having been undermined by the burning, and having fallen into, and been *absorbed* by the under part. And in the year 1646, during the terrible earthquake in the kingdom of Chili, several whole mountains of the Andes disappeared, and were one after another wholly *absorbed* in the earth.

These, and a thousand other accidents of a like kind, prove the truth of *absorptions* in general; some of them leaving level ground in the place of the things *absorbed*, some immense chasms and cracks, and some lakes of fresh or salt water; and it may be, that many immense lakes were formed in ages, of which we have no histories, by the like *absorptions*.

Pliny gives many accounts of the restoring of places thus *absorbed*, but later observations do not give an equal credit to these parts of his history. He tells us, that these restorations are made sometimes in the same place, where the original mountain or island was *absorbed*; sometimes in others, as large spaces of ground arising out of the sea in one place, which had been taken from the land in another; but these seem very vague relations. The islands of Rhodes and Delos, he says, are of this origin, as also that of Anephe beyond Melos, and Nea near Lemnos; that of Ajoue between Lebadus and Teus, and Hiera among the Cyclades; and finally, the island Thia, which he says appeared in his own time. A modern instance of this kind, is the sudden production of the new island near Santorini; but this, and probably all the others also, was not the restoration of any thing before *absorbed*, but the effect of a vulcano under water, which threw up a vast quantity of cinders and sciarri, the whole island, as it is called, consisting of nothing else. In the same manner, in the year 1638, an island was raised near St. Michael's, in the Atlantic ocean, by subterranean fires, which threw up stones, and other subterranean productions, in such quantities, that they formed an island of five miles in length. The mountain raised in one night, in the sea near Puzzoli, is another instance of this sudden production of these mountains: this appeared after one night's violent subterranean conflict, and still keeps its place, and is known under the name of the *Mons Sanctus*. Not one of these, however, appeared in the place of any thing that was *absorbed*; and there is more imagination, than judgment, in supposing them to have any connexion in the laws of nature with the *absorptions* of other places, very distant, and at distant times. *Kircher*'s Mund. Subter. p. 79.

SINKOO, in the materia medica, a name given by some authors to the *lignum aloes*, or agallochum, used in medicine. *Dale*'s Pharm. p. 347.

SINNET, aboard a ship, is a line or string made of rope-yarn, consisting generally of two, six, or nine strings, which are divided into three parts, and are platted over one another, and then it is beaten smooth and flat with a wooden mallet. Its use is to serve the ropes, that is, to keep them from galling.

SINOPICA *terra*, in natural history, the name of a red earth of the ochre-kind, called also *rubrica Sinopica*, and by some authors *sinopis*.

It is a very close, compact, and weighty earth, of a fine glowing purple colour, but in some specimens much deeper than in others, and in some degenerating into paleness; but even in its worst condition, it is a very fine colour. It is of a pure texture, but not very hard, and of an even, but dusty surface. It adheres firmly to the tongue, is perfectly fine and smooth to the touch, does not crumble easily between the fingers, and stains the hands. It melts very slowly in

in the mouth, and is perfectly pure and fine, and of a very auftere aftringent tafte, and ferments very violently with aqua fortis.

It was dug in Cappadocia, and carried for fale to the city Sinope, whence it had its name. It is now found in plenty in the New Jerfeys in America, and is called by the people there *blood-ftone*, from its ftaining the hands to a blood colour, and may probably be had in many other places; and this deferves thoroughly enquiring into, fince there feems not one among the earths more worthy notice. Its fine texture and body, with its high florid colour, muft make it very valuable to painters, and its powerful aftringency equally fo in medicine. The antients were well acquainted with it in fluxes and hæmorrhages, and experience fhews it poffeffes the fame virtues at this time. The deepeft coloured is ever the moft aftringent. *Hill's* Hift. of Foff. p. 60.

SINOPIS, in natural hiftory, a name by which fome authors have called the Sinopic ochre, commonly called *rubrica Sinopica*. *Hill's* Hift. of Foffils, p. 60. See the article SINOPICA *terra*, fupra.

SINUATED *leaf*, in botany. See LEAF.

SINUS (*Cycl.*)—SINUS *of an artery*, is ufed by fome for any part of an artery, where its fides are ftretched out beyond the ordinary proportional dimenfions elfewhere. Med. Eff. Edinb. Abridg. Vol. 2. p. 410.

Morgagni has obferved four fuch *finufes* in the aorta; three of them anfwering to the femilunar valves, and the fourth is all that part of the aorta, between the former *finufes* and the origin of the common trunk of the right fubclavian and carotid arteries. He gives fome reafons to prove, that the nervus acceffforius arifes from the eighth pair, to be joined to the medulla fpinalis. Med. Eff. ibid.

SINUS *of the womb*, is ufed for any cavity within its fubftance. Thefe *finufes* are much of the fame texture with the cells of the fpleen, or rather of the corpora cavernofa penis; being membranous cavities communicating with each other, and having numerous arteries fpread on them, whofe lateral branches open into the cells, from which veins go out to be joined to other veins, that return the blood from the other parts of the womb.

Thefe *finufes* are diftended with blood in the time of the menfes; and their orifices are then alfo enlarged.

During the time of pregnancy the *finufes*, and their canals, that open into the womb, are gradually diftended and enlarged; fo that, at the end of nine months, the *finufes* will contain the largeft fingers, and the canals from them will receive the little finger. Vid. *Monro*, in Medic. Eff. Edinb. Vol. 2. Art. 9.

SIPHAC, a name ufed by fome authors for the *peritonæum*.

SIPHILIS, a name ufed by fome authors for the *lues venerea*, or French-pox.

SIPHITA, a word ufed by Paracelfus, and his followers, with the addition of *parva* and *magna*, for two diforders. The *fiphita parva* fignifies the *chorea fancti Viti*, or St. Vitus's dance; and the *fiphita magna*, walking in time of fleep.

SIPHNIUS *lapis*, in the natural hiftory of the antients, a fubftance found in great plenty in the ifland Siphnus, in the Ægean fea.

It was dug up in large maffes in the neighbourhood of the fea, and when frefh might be cut or worked by the turner into any forts of veffels, by reafon of its foftnefs; but when afterwards burnt and oiled over, it became black and folid, and was fit for any fervice; and the veffels made of it bore the fire very well, and as thofe of earthen-ware with us, for the common offices of boiling, &c. In many parts of Europe they ftill find the fame fubftance, and call it *lapis lebetum*, ufing it in the fame manner. It is no other than the *fteatites*, or *foap-rock*, as it is called with us, common in Cornwall, though our people have not thought of putting it to that ufe. *Hill's* Theophr. p. 106. See the article STEATITES.

SIPHONANTHEMUM, in botany, the name of a genus of plants eftablifhed by Dr. Amman. The name is derived from the Greek σιφον, a tube, and ανθεμον, a flower. The characters of the genus are thefe. The flower confifts of one petal, and is tubulated and divided into feveral fegments at the edge. The piftil arifes from the cup, and finally becomes a fruit refembling four berries, nicely joined together. It is divided into four cells, and contains a number of roundifh feeds. The ftalks of the plant are green and ftriated. The leaves ftand very clofely together, and are placed in no order; they are very narrow, about three inches in length, and much refemble thofe of the willow; they ftand on very fhort pedicles, and are of a very deep green, both on the upper and under-fide. From the alæ of the leaves, or a little above their infertions toward the top of the ftalks, there arife feveral pedicles, of about an inch in length, which divide into feveral others at their tops; ufually each part into three, but often into four or five: thefe are difpofed in the manner of the pedicles of the umbelliferous flowers, and each is terminated by a one-leaved cup, divided into five fegments, from which arife flowers compofed of a flender tube, two or three inches long, of a yellowifh green, which at the end expands into four fegments of a pale yellow: in the middle of thefe there ftands a purple ftyle, which is crooked, and is furrounded by four ftamina of a purple colour, fuftaining each a triangular brown apex. In each of the four cells of the capfule there is contained one large greenifh yellow feed. Act. Petrop. Vol. 8. p. 216.

SIPTACE, in natural hiftory, the name given by the antients to a beautiful bird, of which they were very fond, and which was often kept in their houfes. Some have conjectured this to be the goldfinch, from the fine yellow they defcribe about it; but Pliny plainly makes it the parrot: he tells us, among other things, that it imitated the human voice the beft of all birds.

SIRA, a name by which fome of the chemical writers have called orpiment.

SIRACAUSTUM, a name given by Mefue to a medicine he recommends in acute difeafes.

SIRÆUM, a word ufed by fome to exprefs a fweet decoction, whether given in that form, or firft infpiffated into a fort of rob by evaporation.

SIREN (*Cycl.*)—SIREN, in ichthyology, a name given by Artedi to the fea-monfter often defcribed by authors, but either not exifting at all, or not fo like man as their defcriptions make it.

Artedi fuppofes it to conftitute a peculiar genus of the plagiuri, or cetaceous fifhes. The characters he gives of it are thefe: it has no pinnated tail; the head, neck, and breaft, down to the navel, reprefent thofe of the human fpecies; there are only two fins on the whole body, and thofe ftand on the breaft.

Bartholine, in his Hiftory of Curiofities, defcribes fuch a fifh as this, under the name of *fyrene*, and Barchewitz under the name of *homo marinus*. This author fays that he faw one at fea, and that it is wholly different from the manati, and from all other fifhes. The Philofophical Tranfactions alfo contain an account of a fea-man feen in the American feas, and feveral other writers of credit give countenance to the ftory. Their defcriptions tell us, that from the navel to the tail it is one fhapelefs mafs of flefh, without any appearance of finny tail, or any other part of the ftructure of a fifh. The pectoral fins refemble hands, and are compofed of five bones, or fingers, joined by a membrane. With thefe it fwims. It were much to be wifhed, that fome accurate ichthyologift might have an opportunity of feeing and examining this creature, if it really exifts different from the other animals of the fea. Artedi feems to doubt the truth of the accounts, but thinks it better not to judge of a thing not yet feen, than to pronounce any thing rafhly againft the accounts of creditable authors. *Artedi*, Gener. Pifc. p. 52.

SIREN is alfo a name given by Mouffet, and other authors, to a fpecies of bee; of which they diftinguifh two kinds, a larger and a fmaller. Thefe differ greatly from the common bee, in that they live folitary, and never unite into fwarms, or build nefts, or make combs.

SIRI, among the Romans, were fubterranean caves, or vaults, in which wheat could be kept found and frefh for fifty years. *Pitifc.* Lex. Ant. in voc.

SIRIASIS, a name given by medical writers to a difeafe to which children are fubject; it confifts in an inflammation of the brain and its membranes, and is attended with a depreffure of the fontanella, or hollownefs of the eyes, a burning fever, a palenefs and drynefs of the whole body, and an utter lofs of appetite.

SIRICON *plumbi*, a name given by fome chemical writers to calcined lead, or the grey powder made of lead by a flight calcination in an open fire.

SISARUM, *fkirret*, in botany, the name of a genus of umbelliferous plants, the characters of which are thefe. The flower is of the rofaceous kind, being compofed of feveral petals, arranged in a circular form. The cup becomes a fruit compofed of two feeds, which are flender and gibbofe on one fide, and flat on the other. To this it is to be added, that the roots are feveral large and long ones, hanging from the fame head.

We know of no other fpecies of this genus, but the common *fifarum*. *Tourn.* Inft. p. 308. See SKIRRET.

The tafte of the *fkirret*-root has fomewhat of a bitternefs and fubaftringency in it. It ftrengthens the ftomach, and is of good nourifhment. It proves diuretic, and is by fome pretended to be a remedy againft the ill effects of mercury; but this is an idle opinion.

SISER, in botany, a name given to the fkirret, otherwife called the white carrot, or yellow parfnep. See the article SISARUM.

SISKIN, in zoology, the common Englifh name of a finging bird, kept in cages in fome parts of England, where it is common, and called by authors *fpinus* and *ligurinus*. *Ray's* Ornithol, p. 192. See the article SPINUS.

SISON *fyriacum*, in botany, a name given by fome authors to the ammi, or bifhop's weed, a plant, whofe feeds were once much in ufe in medicine. *Ger.* Emac. Ind. 2.

SISSITIEPTERIS, in botany, a name ufed by Pliny, and fome others of the old authors, for the *pimpinella*, or burnet. *Ger.* Emac. Ind. 2.

SISTRUM, in antiquity, an inftrument ufed for beating time in concerts. It was a plate of founding metal, of an oval form, the upper part of which was adorned with three figures; that of a cat with a human face in the middle, the head of Ifis on the right-fide, and the head of Nephthys on the left. It was filled with wires of the fame metal, which ferved to beat againft the plate when fhaken. Mem. Acad. Infcript. Vol. 7. p. 249, feq.

SISYMBRIUM, *fpearmint*, in botany, the name of a genus of plants, the characters of which are thefe. The flower confifts of four leaves, and is of the cruciform kind. The piftil arifes from the cup, and is finally turned into a long pod, divided into two cells by an intermediate membrane, and furnifhed with roundifh feeds. To thefe marks it may be added, that there is a peculiar general appearance of all thefe plants, which will eafily diftinguifh them, at firft fight, from all the others of the fame clafs.

The fpecies of *fifymbrium*, enumerated by Mr. Tournefort, are thefe. 1. The water-*fifymbrium*, or common water-crefs. 2. The purple-flowered broad-leaved Pyrenean *fifymbrium*. 3. The fmooth rocket-leaved *fifymbrium* with yellow flowers, commonly called *barbarea*, and *winter-creffes*. 4. The fmall early-flowering fmooth rocket-leaved *fifymbrium*, or winter-crefs. 5. The double-flowered fmooth rocket-leaved *fifymbrium*. 6. The rough-rocket-leaved *fifymbrium* with yellow flowers. 7. The fhort-podded radifh-leaved water-*fifymbrium*. 8. The radifh-leaved fhort-podded water-*fifymbrium* with variegated leaves. 9. The fhort-podded water *fifymbrium* with more deeply divided leaves. The three laft are ufually called by authors *water-radifhes*. 10. The creeping water-*fifymbrium* with leaves like thofe of the nafturtiums. This is called by fome *water-rocket*. 11. The fmall rough-podded marfh-*fifymbrium*, called by many *rough-podded muftard*. 12. The fmall fmooth-podded marfh-*fifymbrium*. 13. The wormwood-leaved annual *fifymbrium*, called by many authors *fophia chirurgorum*. *Tourn.* Inft. p. 226.

Sifymbrium, among the Romans, was one of the ingredients, whereof the nuptial garlands were compofed. See NUPTIAL and GARLAND.

SISYMBRIUM, in botany, is alfo a name ufed to exprefs the wild water-mint. *Dale*'s Pharm. p. 205. See the article MENTHA.

SISYRA, among the antients, a woolly fkin ufed for a covering to beds. *Hofm.* Lex. Univ. in voc.

SISYRINCHIUM, in botany, the name of a genus of plants, the characters of which are thefe. The flower and fruit are the fame with thofe of the iris and xiphion, but the root is compofed of two bulbs, the one lying upon the other, as in the gladiol and crocus.

The fpecies of *fifyrinchium*, enumerated by Mr. Tournefort, are thefe. 1. The large *fifyrinchium* with the flower marked with a yellow fpot. 2. The large *fifyrinchium* with the flower marked with a white fpot. And 3. the leffer *fifyrinchium*. *Tourn.* Inft. p. 365.

SITHCUNDMAN, in our old writers, one whofe province it was to lead the men of a town or parifh. Leg. Inæ. c. 56. Dugdale fays, that in Warwickfhire the hundreds were formerly called *fithefoca*, and that *fithefocundman* and *fithcundman* was the chief officer within fuch a divifion, i. e. the high-conftable of the hundred. *Dugd.* Antiq. Warwick. *Blount.* in voc.

SITHESOCA, in our old writers, is ufed to denote the diftrict now called an *hundred*. The word is Saxon, fignifying a franchife, or liberty. Rot. Parl. 16 Hen. II. *Blount.*

SITICINES, among the Romans, perfons who founded a kind of trumpet, having a very mournful tone, at the burying the dead. *Danet.* in voc. See the articles BURYING and BURIAL.

SITONÆ, Σιτῶναι, among the Athenians, officers appointed to lay in corn for the ufe of the city, for which purpofe the ταμίας τῆς διοικήσεως, or the public treafurer, was to furnifh them with as much money as they had occafion for. *Potter*, Archæol. Græc. l. 1. c. 15. Tom. I. p. 83.

SITTA, in the Linnæan fyftem of zoology, the name of a diftinct genus of birds, ufually confounded with the woodpecker-kind. The characters of this genus are, that the foot has three toes before, whereas the woodpecker has but two fore-toes on each foot; the bill is angular, and ends in the form of a wedge, and the tail is raifed. The grey, or afh-coloured picus is of this genus. *Linnæus*, Syftem. Natur. p. 45.

The *picus cinereus*, or grey woodpecker, is called in Englifh the *nut-hatch* or *nut-jobber*.

It is a fmall bird, not quite fo large as the chaffinch. Its head, neck and back are grey; its fides under the wings are red, and its throat and breaft of a pale yellow, with a mixture of a chefnut brown. The lower part of its belly is covered with red feathers, with white tips or ends, and it has a long black ftreak on each fide, running from the angle of the beak to the neck. Its long wing-feathers are black, and its tail variegated with black and grey. Its legs are red, and its toes ftand three before, and one behind; not as in the woodpecker, two each way. It builds in holes of trees, and when their entrance is too large, artfully ftops them up with mud. It feeds on infects and fruits. It hoards nuts for the winter, and breaks them by fticking them in a cleft of a tree, and ftriking them with its beak. *Ray*'s Ornitholog. p. 98.

SIUM, in botany, the name of a genus of umbelliferous plants, the characters of which are thefe. The flower is of the umbelliferous kind, being compofed of feveral unequal leaves, arranged in a circular form. The cup finally becomes a roundifh fruit, compofed of two feeds, which are gibbofe and ftriated on one fide, and flat and plain on the other. To this it is to be added, that the leaves ftand by pairs on the ribs, and have a fingle one to terminate the ends.

The fpecies of *fium*, enumerated by Mr. Tournefort, are thefe. 1. The common, or long-leaved *fium*, or water-parfnep. 2. The *fium* with ferrated leaves. 3. The great broad-leaved *fium*. 4. The *fium* with deeply jagged leaves. 5. The creeping umbelliferous *fium*. 6. The *fium* which has umbels at the joints of the ftalks. 7. The field-*fium*, called *honewort*, or *corn-parfley*, and by authors *felinum fii foliis*. And 8. the aromatic *fium*, or *fifon* of the fhops, called by many *amomum*, and *Macedonian parfley*. *Tourn.* Inft. p. 308.

SIXTH (*Cycl.*)—SIXTH, in mufic, is not properly an original concord, as is advanced in the Cyclopædia, fince it arifes from the fubtraction of the third from the octave. There are properly but three original concords, the octave, fifth, and third major. Philof. Tranf. Nº 481. p. 267. See the article INTERVAL.

Diminifhed SIXTH, in mufic. See DIMINISHED *fixth*.

SIZE (*Cycl.*)—The fhreds and parings of leather, parchment, or vellum, by being boiled in water, and ftrained, make *fize* [b]. This fubftance is ufeful in many trades. Mr. Boyle mentions, among other ufes, that fine red ftands, and hanging fhelves, are coloured with ground vermilion tempered with *fize*, and when dry, are laid over with common varnifh [c].—[[b] See GLUE, *Cycl.* [c] *Boyle*'s Works Abridged, Vol. 1. p. 150.]

Gold SIZE. See GOLD *fize*.

SIZEL, in coining, is ufed where pieces of money are cut out from the flat bars of filver, after having been drawn through a mill into the refpective fizes or dimenfions of the money to be made; the refidue is called *fizel*, and is melted down again. *Lownd*'s Eff. upon Coin, p. 96.

SIZING, in mineralogy, a term ufed by the Cornifh miners for a peculiar method of feparating the purer from the impurer parts of an ore by means of fieves. When the ore has been powdered, they put it into a wire-fieve with fine holes, and in this they fift it till the fine part goes through: this is properly what is called *fizing*. They fend the larger, or coarfer part, to be powdered again, and putting the reft into a fieve with a clofe bottom, they let in a ftream of water from a cock, and by means of continued fhaking it about, they caufe the lighter and fouler parts to be wafhed over the rims of the fieve, and the remaining powder is the black tin.

SKAITE, in ichthyology, the Englifh name of a fpecies of the ray-fifh, called by the generality of authors *raia undulata*, and *raia lævis*, and by fome *rubus*.

It is diftinguifhed by Artedi by the name of the variegated *ray-fifh* with the middle of the back fmooth, and with only one row of fpines in the tail. See RAJA.

SKEGG, in a fhip, that fmall and flender part of the keel, which is cut flanting, and left a little without the ftern-poft. It is now much out of ufe.

SKELETON (*Cycl.*)—We have, in the Philofophichal Tranfactions, an account of an human *fkeleton*, all the bones of which were fo united, as to make but one articulation from the back to the os facrum, and downwards a little way. On fawing fome of them, where they were unnaturally joined, they were found not to cohere throughout their whole fubftance, but only about a fixth of an inch deep all round. The figure of the trunk was crooked, the fpinæ making the convex, and the infide of the vertebræ the concave part of the fegment. The whole had been found in a charnel-houfe, and was of the fize of a full grown perfon.

Vegetable SKELETON. The preparations of leaves, fruits, roots, &c. called *vegetable fkeletons*, are made in this manner. Chufe for this purpofe the leaves of trees or plants, which are fomewhat fubftantial and tough, and have woody fibres, fuch as the leaves of orange, jafmine, bay, laurel, cherry, apricot, peach, plum, apple, pear, poplar, oak, and the like; but avoid fuch leaves as have none of the woody fibres, which are to be feparated and preferved by this method; fuch are the leaves of the vine, lime-tree, and the like. The leaves are to be gathered in the months of June or July, and fuch to be chofen as are found and untouched by caterpillars, or other infects. Thefe are to be put into an earthen or glafs veffel, and a large quantity of rain-water to be poured over them; and after this they are to be left to the open air, and to the heat of the fun, without covering the veffel; when the water evaporates, fo as to leave the leaves dry, more muft be added in its place: the

the leaves will by this means putrefy, but they require a different time for this, ſome will be finiſhed in a month, and others will require two months, or longer, according to the hardneſs of the parenchyma of them. When they have been in a ſtate of putrefaction ſome time, the two membranes will begin to ſeparate, and the green part of the leaf to become fluid; then the operation of clearing them is to be performed. The leaf is then to be put upon a flat white earthen-plate, and covered with clear water; and being gently ſqueezed with the finger, the membranes will begin to open, and the green ſubſtance will come out at the edges; the membranes muſt be carefully taken off with a finger, and great caution muſt be uſed in ſeparating them near the middle rib. When once there is an opening toward this ſeparation, the whole membrane always follows eaſily; when both membranes are taken off, the *ſkeleton* is finiſhed, and it is to be waſhed clean with water, and then preſerved between the leaves of a book.

The fruits are diveſted of their pulp, and made into *ſkeletons* in a different manner. Take, for inſtance, a fine large pear that is ſoft, and not ſtrong; let it be nicely pared without ſqueezing it, and without hurting either the crown or the ſtalk; then put it into a pot of rain-water, cover it, ſet it over the fire, and let it boil gently till it is perfectly ſoft, then take it out, and lay it in a diſh filled with cold water; then hold it by the ſtalk with one hand, and with the other hand rub off as much of the pulp as you can with the finger and thumb, beginning at the ſtalk, and rubbing it regularly towards the crown. The fibres are moſt tender toward the extremities, and are therefore to be treated with great care there. When the pulp is thus cleared pretty well off, the point of a fine penknife may be of uſe to pick away the pulp ſticking to the core. In order to ſee how the operation advances, the foul water muſt be thrown away from time to time, and clean poured on in its place. When the pulp is in this manner perfectly ſeparated, the clean *ſkeleton* is to be preſerved in ſpirit of wine.

Skeletons of roots which have woody fibres, ſuch as turneps, and the like, muſt be made by boiling the root without peeling it till it be ſoft, that the pulp may be ſqueezed away by the fingers, in the ſame manner, in a diſh of water. Many kinds of roots are thus made into elegant *ſkeletons*, and the ſame method ſucceeds with the barks of ſeveral kinds of trees; which when thus treated, afford extremely elegant views of their conſtituent fibres. Philoſ. Tranſ. Nº 416.

SKEW, or SKILL *facets*, among jewellers. See FACETS.

SKIN (*Cycl.*)—The cuticle, or ſcarf-*ſkin* of the human body, is remarkable for its ſcales, and for its pores. Its ſcales are wholly a microſcopical diſcovery, for being ſo very minute, that two hundred of them may be covered with a grain of ſand, they never could have been diſcovered by the naked eye. Theſe are placed on our *ſkin* as on fiſhes, that is three deep, or each ſcale ſo far covered by two others, that only a third part of it appears; and theſe lying in this manner over one another, ſeem the reaſon of the *ſkin's* appearing white; for about the mouth and lips, where they only juſt meet together, and do not fold over, the blood-veſſels are ſeen through, and the parts appear red. The perſpirable matter is ſuppoſed to iſſue from between theſe ſcales, which lie over the pores, or excretory veſſels, through which the watery and oily matters perſpire; and theſe may find vent in a hundred places round the edges of each ſcale: ſo that if a grain of ſand can cover two hundred of theſe ſcales, it may cover twenty thouſand places through which perſpiration may iſſue forth.

A piece of the *ſkin* taken from between the fingers, from the forehead, neck, arms, or any other ſoft part of the body, which is not hairy, ſerves to ſhew theſe ſcales; for where the ſkin is become hard and callous, they are faſtened confuſedly together. They are generally compoſed of five ſides, and may be ſeen very diſtinctly if ſcraped off with a penknife, and applied to the microſcope in a drop of water. *Baker's* Microſcope, p. 169.

Every part of the *ſkin* of the human body is alſo full of excretory ducts, or pores, which continually emit the ſuperfluous humours from among the maſs of the circulating fluid. In order to view theſe pores, cut a ſlice of the upper *ſkin* with a ſharp razor, as thin as poſſible, then immediately cut alſo a ſecond ſlice from the ſame place, which apply to the microſcope; and in a piece of this, not larger than what a grain of ſand can cover, there may be diſcovered innumerable pores as plainly, as little holes pricked in paper by a fine needle may be perceived, when it is held up againſt the ſun. The ſcales of the upper *ſkin* prevent any diſtinct view of the pores, unleſs they are thus cut off firſt, or elſe ſcraped away with a penknife; but if a piece of the *ſkin* between the fingers, or in the palm of the hand, be ſo prepared, and then examined, the light will be ſeen very beautifully through its pores. *Lewenhoek*, Arcan. Nat. Tom. 3. p. 413.

Mr. Lewenhoek has attempted to give ſome ſlight notion of the number of the pores in the human body: he ſuppoſes that there are a hundred and twenty ſuch pores in a line one tenth of an inch long; however, to keep within compaſs, he reckons only a hundred; an inch in length will then contain a thouſand in a row, and a foot twelve thouſand. According to this computation, a foot ſquare muſt have in it a hundred and forty four millions; and ſuppoſing the ſuperficies of a moderate ſized man to be fourteen feet ſquare, there will be in his ſkin two thouſand and ſixteen millions of pores.

Dr. Grew has obſerved that the pores, through which we perſpire, are more remarkably diſtinguiſhable in the hands and feet; for if the hands be well waſhed with ſoap, and examined with but an indifferent glaſs in the palm, or upon the ends and firſt joints of the thumb and finger, there will be found innumerable little ridges parallel to each other, and of equal bigneſs and diſtance; and upon theſe ridges the pores may be diſcovered by a very good eye, even without a glaſs, lying in rows, but viewed through a good glaſs, every pore ſeems like a little fountain, with the ſweat ſtanding therein as clear as rock water; and this, when wiped away, will be found to be immediately renewed again.

Probably fleas, gnats, and other inſects, which feed on our blood and humours, make no new holes, but prey upon us through theſe pores. Philoſ. Tranſ. N 159.

SKIN, in commerce. The Indians in Carolina and Virginia dreſs buck and doe-*ſkins* in this manner: the felt being taken off they ſtrain them with lines, or otherwiſe, much like the clothiers racks, in order only to dry them. When the hunting time is over the women dreſs the *ſkins*, by putting them in a pond, or hole of water, to ſoak them well; then with an old knife, fixed in a cleft ſtick, they force off the hair whilſt they remain wet. This done, they put them into a kettle, or earthen-pot, and a proportion of deers brain dried and preſerved for this purpoſe, is put in along with them; this veſſel is ſet on the fire till they are more than blood-warm, which will make them lather and ſcour clean; after this, with ſmall ſticks, they wreſt and twiſt each *ſkin*, as long as they find any wet to drop from them, letting them remain ſo wreſted for ſome hours, and then they untwiſt and ſtretch each of them in a ſort of rack, ſo that every part is extended; and as the *ſkin* dries they take a dull hatchet, or ſome ſuch inſtrument, and rub them well over to force all the water and greaſe out of them, till they become perfectly dry, and then their work is done.

In this manner one woman (for the men never employ themſelves in this work) will dreſs eight or ten *ſkins* in a day, that is, begin and finiſh them. Phil. Tranſ. Nº 194.

SKINK, *ſcincus*, in zoology, &c. See SCINCUS.

SKINUS, σκῖνος, a name given by the antient naturaliſts to the lentiſk-tree, and alſo to a peculiar ſpecies of the ſquill, or ſcilla; which was not nauſeous and emetic as the common ſquill, but eſculent and pleaſant to the taſte.

The generality of writers, even among the antients themſelves, have not obſerved the ſynonymous uſe of this word, and tranſcribing at random paſſages from one another, have confounded the names of the lentiſk-tree and of this eſculent ſquill, and related of the one what the original writer ſaid of the other. Hence many of the abſurdities which we find in the works of ſome, but which are by no means to be attributed to all of them.

Pericles was called, by way of deriſion among the comic writers of his time, *Skinocephalus*, this term expreſſing his having a head like the *ſkinos*, muſt be wholly unintelligible to thoſe, who ſuppoſed it meant as the name of the lentiſk-tree; but when it was underſtood to be meant of the ſquill, the ſatire was plain, as a large and miſhapen head, ſuch as that of Pericles was, could not eaſily be better likened to any thing, than to the irregular, large, and oblong bulbous root of this plant.

Epicharmus, in Athenæus, names the *ſkinos* as a kind of eatable ſquill; and Theophraſtus expreſsly ſays, that the roots of all ſquills were not eatable, but that they only eat thoſe of the *ſkinos*, or, as others called it, the *Epimenedian ſquill*, a ſort of that plant ſo called, after the name of one Epimenides, who firſt brought it into uſe. The after-writers run into great errors about this word, ſome of them tranſlating Theophraſtus's epithet into a ſubſtantive, and diſtinguiſhing the Epimenedium from the ſcilla. Pliny, in particular, is guilty of this error. This is the peculiar ſpecies of ſquill, which the Athenians afterwards diſtinguiſhed from the common kind, by the name *ſkinus*. Theopompus mentions the *ſkinus* as an eſculent kind of ſquill; and, in general, the word oftener occurs as the name of the ſquill, than as the name of the lentiſk-tree.

Theophraſtus mentions the inſerting an eſculent root on the *ſkinos*, or ſkilla, giving the choice of either of thoſe roots, and ſays that it will thrive much better on this, than in the earth alone; the tranſlators have rendered this the lentiſk: but where is the probability of this excellent botaniſt's adviſing the grafting an eſculent root upon a tree, or giving a tree, and a common bulbous plant, as indifferent to the choice which was to be uſed? *Pliny*, lib. 23. cap. 5. *Theophraſtus*, lib. 5. c. 7. See LENTISCUS.

SKIPPER, an Engliſh name for the common gar-fiſh. See ACUS.

SKIRRET, *ſiſarum*, in botany, &c. See SISARUM.

The *ſkirret*, though one of the moſt wholeſome and nouriſhing of all the eſculent roots, is very little cultivated with us,

It may be propagated either by fowing the feeds, or by planting the flips and off-fets, but the firft is much the beft method. It fhould be fowed on a moift rich foil, in the beginning of February; in April the young plants will come up, when they muft be cleared of weeds, and houghed up to three inches afunder; and about a month afterwards they muft be thinned a fecond time, leaving them only fix inches diftant. After this they muft be carefully kept clear from weeds, and when their leaves are decayed, they fhould be taken up for ufe; but this fhould only be done as they are wanted, for they fpoil with lying out of the ground. The leaves decay in October, and from that time till the middle of March the roots are in feafon; after this the roots become good for little. *Miller's* Gard. Dict.

SKITTISH, in the manege. A horfe is faid to be *fkittifh*, in French *ecouteux*, or *retenu*, that leaps inftead of going forward; that does not fet out, or part from the hand freely, nor employ himfelf as he ought to do.

SKOUT, in zoology, a name given by the people of Yorkfhire to the *lomwia*, called in many places the *kiddaw*, and in Scotland the *auk*, or razor-bill, another of the webfooted water-fowl. *Ray's* Ornitholog. p. 244. See the articles ALKA and LOMWIA.

SKRABBA, in ichthyology, a name given by fome to a fifh called by Jonfton and Schoneveldt the *fcorpius marinus*, but wholly different from the *fcorpæna* of other authors.

It is a fpecies of cottus, and is diftinguifhed by Artedi by the name of the *cottus* without fcales, with feveral prickles upon its head, and with the upper jaw fomewhat lower than the other. See the article COTTUS.

SKULL (*Cycl.*)—It is not uncommon to find in fome human *fkulls* a different ftructure and conformation from that which nature has given to others, or to the generality of the fpecies.

Frequently there are met with heads, the fagittal future of which is prolonged to the root of the nofe, and divides the coronal bone into two parts: and there have been anatomifts, who have judged this fort of conftruction of the *fkull* peculiar to one fex, rather than common to both.

To find the true caufe of this, we are to have recourfe to the ftate of the *fkull* in the infancy. This bone is, at that time, always found divided into two lateral portions; fo the fame feparation, which is found between the two fides, is found alfo between the two pieces, which afterwards compofe the coronal bone. The two pieces of this coronal bone unite one with another, by means of their indented edges, and thefe afterwards coalefce fo perfectly, that the future is obliterated; and this coalefcence, which thus in proper time takes place in the coronal bone, fometimes extends itfelf, alfo, to almoft all the other bones of the *fkull*; but this only happens in old age. But if, on the contrary, the two pieces, of which the coronal bone is compofed, acquire their full thicknefs and hardnefs, before this coalefcence is brought about, the future remains, and is not obliterated, except in extreme old age. This reflexion may be alfo carried much farther.

In the *fkulls* of a great number of infants, the coronal and the two fides fo perfectly unite, as not to leave the leaft trace of their original feparation. It feems as if the bones, having expanded and grown in thefe early ftages too faft for the brain, have been united to one another while yet foft and tender: but when the brain, on the other hand, grows too faft for the bones of the *fkull*, thefe bones, preffed more from within outwards than any other way, have little difpofition to unite with one another; and thus acquiring their thicknefs and hardnefs before their coalefcence, they become much lefs inclined to coalefce than before.

From thefe confiderations we may conclude, that in thofe infants, in which the growth of the brain is flow, and that of the bones of the *fkull* quick, the future, which is between the two portions of the coronal bone, is very quickly obliterated; and, on the contrary, when the encreafe of the brain is quick, and the growth of the bones is flow, the future, which divides the coronal bone into two pieces, is found to a great age.

That which is the *fkull* in the more advanced ftate of the infant, is originally no other than a membrane, which is afterwards to offify: not unfrequently the offification is impeded, in different parts of this membrane; and in the *fkulls* of young fubjects it is common to fee thefe diftinct parts, which remain membranous while the reft of the *fkull* has acquired its proper bony hardnefs. If the caufe, which impeded the progrefs of the offification, fubfifts fo long, as till the other parts of the *fkull* are hardened into bone, and have their full growth and hardnefs, then will that, which fhould have been naturally only one bone, form two.

This is the origin of the fingular and unnatural futures, found in fome human *fkulls*, and called by fome *fupernumerary futures*. Sometimes there are, from this caufe, fuch fupernumerary futures in almoft all the bones of the *fkull*. The os planum frequently is found thus divided into two; and from the fame principle in nature it is, that a fmall future is fometimes found in the maxillary bone, below the orbit, along the canal, which forms the lower orbitary cavity: the place where this little future is found has happened to remain a long time membranous, and the offification at laft taking place on the two edges of the remaining membrane, there has been found a future.

In other bones of the *fkull* we alfo frequently meet with larger or fmaller fpaces, which have continued membranous; and there are inftances, in which the offification may be plainly perceived juft begun in the center of the membranous fpots.

It might be fuppofed that the brain was little liable to an unnatural growth, or expanfion, when we confider that the brain is no other than a vaft affemblage of pipes, or tubes, of a moft extreme finenefs, and that the particles, which compofe thefe tubes, have but a very weak band of union one with another. Indeed we know very well, that when an injection has penetrated to the cortical fubftance of the brain, if that fubftance be macerated a little in water, its parts detach themfelves from one another, the veffels become wholly deftroyed, and there remains nothing but a number of extremely fine filaments of the matter of the injection, which has found its way into thefe veffels, and been formed into their fhape by cooling in their cavities. As there are found, however, a great number of *fkulls*, which have a fingular and odd configuration, it cannot but be, that the brain muft be expanded into the fame form. We are informed, that the people of fome nations prefs the forepart of the heads of their children, as foon as born, with confiderable violence, and continue this, in order to reduce the forehead to a flatnefs; but thefe *fkulls* are always found to get in length behind what they want before.

Sometimes there has been obferved, in the *fkulls* of perfons of an advanced age, in the middle of the fagittal future, a deep impreffion, or finking in, which had remained there from infancy; but nature, in this cafe, fupplies the cavity with two protuberances of bone from the fides of the adjoining parts; and fome *fkulls* are found very narrow, and of a remarkable length, nature giving one way the room fhe denied the other. Many other fingular conftructions of the *fkull* have been obferved by anatomifts; and probably in the perfons, to whom they have belonged, the brain has been able to perform its functions but badly. Be that as it will, it is certain that the brain has expanded, and formed itfelf to the fhape of the *fkull* in all thefe its unnatural figures; and neceffarily the parts, of which the brain in fuch cafes is compofed, have taken a very different figure and arrangement from what nature intended: and in this cafe it cannot be, but that fome portions of the brain have extended themfelves farther than they naturally fhould have done, and others much lefs than was allotted to them. Mem. Acad. Scienc. Par. 1740.

Bones of the SKULL. The eight principal bones of the *fkull* are ordinarily divided into common and proper. By proper bones anatomifts mean thofe, which are wholly employed in forming the globe of the *fkull*, and of thefe they reckon fix; the os frontis, the two parietal bones, the occipital bone, and the offa temporum: the common bones are thofe which contribute to form the face, as well as the *fkull*, *viz.* the os ethmoides, and the os fphenoides. But this divifion is not juft, for the os frontis, and offa temporum, deferve as much to be called common, as the two that are ufually reckoned fo; and thus, inftead of fix, there would be only three proper bones, the offa parietalia, and os occipitis; and inftead of two, there would be five common ones, the os frontis, offa temporum, os ethmoides, and os fphenoides. *Winflow's* Anatomy, p. 21.

The adhefion of the pericranium to the *fkull*, has been thought a fure fign of the bones being entire, but this is a miftake; and the feparation of the cranium from the *fkull*, is as uncertain a fign of the cranium's being broken. Mem. de l'Acad. de Chirurg. Tom. 1.

We have fome very particular obfervations on the bones of the human *fkull*, by Mr. Hunauld, in the Memoires de l'Acad. Royale des Sciences, An. 1730.

Concealed injuries of the SKULL. When a blunt inftrument is the occafion of an injury on the cranium, if the injured part does not fufficiently appear of itfelf, great induftry is to be ufed to difcover it. Where the common integuments appear tumid and foft, they are in this cafe to be divided to the bone; but in making the incifion, great care muft be taken not to lay too much ftrefs upon the knife, left fplinters of the fractured cranium fhould by that means be forced in upon the brain. The beft way to make this incifion is in form of the letter X, and about an inch and half in length; lifting up the fkin at each angle, and leaving the bone bare. The blood that is fpilt is to be taken up with a fpunge, and dry lint ftuffed between the fkin and the cranium; and having thus found out the injured part of the cranium, the trepan is to be applied, if it be found neceffary. If fplinters of the bone are now found, they muft be removed either with the fingers or the forceps, or, when they hang to the pericranium, with fciffors; but when they adhere pretty firmly to the neighbouring parts of the cranium, it is more advifeable to replace them, than to endeavour to remove them by violence. *Heifter's* Surgery, p. 85.

Fissures of the SKULL, cracks in the bone of the *skull*, made by falls, blows, or other injuries. When these are attended with no other bad symptoms but white, yellow, or brown spots upon the face of the bone, they may be remedied with boring several small holes through the surface of the *skull*, down to the diploe, and dressing with balsamic medicines: but where violent symptoms come on, which demonstrate an extravasation of blood in the cavity of the cranium, the trepan is to be used without delay.

Depressions of the SKULL, a denting in of the bone of the *skull* by a blow, without any manifest fracture, or, at the utmost, with such a fracture, that from its flexibility it does not start out by means of it, but continues to adhere firmly to the neighbouring bones. The *skulls* of infants are frequently subject to this, but in adults this case cannot happen; for the bones in them are become so rigid, that it is impossible to beat in any part of the cranium, without beating the bone to pieces. These injuries of the cranium are called by the surgeons *fractures*, and the brain is frequently injured by these accidents, and its actions disturbed. The first thing to be done, to give relief in this disorder, is to lift up any part of the bone that is depressed, or beaten in upon the brain, or to remove any other body by which it is compressed. Sometimes a splinter, which is quite separated from the rest of the bone, is driven into the cavity of the cranium, and lies constantly vellicating the brain and its membranes with its pointed parts; this is to be removed without delay.

When slight depressions are made in the *skulls* of infants, without bringing on any bad symptoms, the forcible methods of raising the depressed part are not to be used, but medicated bags, boiled in spirit of wine, warm fomentations, and such remedies, are to be applied; and lastly, a plaster of melilot to cover all. These slight applications frequently cure such little depressions, and prevent the mischievous consequences which might be expected from them. When a very large depression, however, happens to infants, the elevation, or restitution of the parts is to be performed in the following manner. After shaving the part, apply a plaster made of gummy and very sticking ingredients, and spread upon very strong leather, with a cord fastened to the middle of it: this plaster is to be laid on pretty warm, and left in its situation till grown cold; the surgeon then taking hold of the cord, which is fastened to it, is to pull it directly upwards, and with it the depressed part of the cranium will often rise, and be restored to its place. When this method does not succeed at the first trial, it is to be repeated; and when this fails, the application of a cupping-glass to the depressed part will sometimes succeed, especially if you stop the patient's breath, both at the nose and mouth, during the operation: but if neither the plaster nor cupping prove successful, it will be necessary to take in the assistance of an instrument.

But when the cranium is so depressed, whether in adults or infants, as to suffer a fracture or division of its parts, it must instantly be relieved. Some praise very much the use of a sternutatory powder on this occasion, affirming, that the distention of the brain is so violent in the act of sneezing, that it will restore the depressed parts of the bone to their former situation: but the ill consequences, that may attend this practice, are so grievous, that it ought wholly to be rejected, and the trepan and elevatories always to be used. *Heister's* Surgery, p. 87.

Wounds of the SKULL. In wounds of the cranium, or *skull*, the first business is to find whether they are terminated in the external parts of the cranium, or whether they penetrate into its cavity. This is to be known by the eye. 2. By the probe, which however must be used very gently here, for fear of bringing on farther mischief. 3. By examining the instrument with which the blow was given, and considering the degree of force with which it was impelled. And lastly, the presence, or absence of violent bad symptoms. A violent blow upon the head will always be attended with vomitings and vertigoes, and blood will be discharged by the nose, ears, and mouth, and the wounded person will lose also his speech and senses. These disorders will appear sometimes sooner, sometimes later, but always are more violent than otherwise, when the wound is made by a fall, or by some blunt instrument; in which cases the cranium is usually much shattered. The blood which discharges itself by the wound, when that is made by a sharp instrument, will insinuate itself between the common integuments and the cranium: in the contusions that are made with blunt instruments, sometimes it will be concealed under the cranium, and by corrupting the pericranium and cranium, will bring on ulcers, and caries of the bone, and frequently occasions fevers, convulsions, and death. *Heister's* Surgery, p. 82.

SKY (*Cycl.*)—SKY-*colour*. To give this colour to glass, set in the furnace a pot of pure metal of fritt from rochetta, or barillia, but the rochetta fritt does best; as soon as the metal is well purified, take for a pot of twenty pound of metal six ounces of brass calcined by itself, put it by degrees, at two or three times, into the metal, stirring and mixing it well every time, and diligently scumming the metal with a ladle: at the end of two hours the whole will be well mixed, and a proof may be taken; if the colour be found right, let the whole stand twenty four hours longer in the furnace, and it will then be fit to work, and will prove of a most beautiful *sky-colour*. *Neri's* Art of Glass, p. 40.

SLABBERING-*bit*, in the manege. See the article MASTIGADOUR.

SLABS *of tin*, the lesser masses, which the workers at the tin-mines cast the metal into: these are run into moulds made of stone. *Ray's* English Words, p. 124.

SLACK *a leg*, in the manege, called in French *mollir la jambe*, is said of a horse when he trips or stumbles.

SLACK *the hand*, is to slack the bridle, or give a horse head.

SLACKEN, in metallurgy, a term used by the miners to express a spungy and semivitrified substance, which they use to mix with the ores of metals, to prevent their fusion. It is the scoriæ or scum, separated from the surface of the former fusions of metals. To this they frequently add limestone, and sometimes a kind of coarse iron-ore, in the running of the poorer gold-ores.

SLATCH, at sea. When a rope or cable hangs slack, the seamen call the middle part, which hangs down, *the slatch of the cable*, or rope: so also, after long foul weather, if there come a small interval of fair, they say, *this is a slatch of fair weather*.

SLATE (*Cycl.*)—The strata of this stone usually lie very much inclining, and are of a considerable extent. At Mullinecke, in Wales, the *slate* lies thus, and reaches from near the surface to the level of the tide that flows up the river, in the cliffs of which it lies. It may go much deeper, for it has not been examined to the bottom there; but what is observable in this place, is, that there are evident flexures or bendings in several parts of the strata, and these always run from the top downwards; in the other parts of the same strata there are several perpendicular fissures or cracks, but they are small like cracks, and always empty.

It appears from this, that at the time when the bed of *slate* cracked in some places, it was so tough, as to abide being bent in others, by which means these flexures were formed. Sometimes the beds of *slate* are cracked at the angles of these flexures, the intermediate mass, though parted from the rest, lying obliquely. It is observed thus cracked, also, in many parts of Yorkshire. *Woodward's* Cat. of Fossils, Vol. 2. p. 5.

Irish SLATE. See TEGULA *Hybernica*.

SLAVE. For the custom of marking, or stigmatizing slaves, see STIGMATIZING.

SLAUGHTER (*Cycl.*)—SLAUGHTER-*skins*, a term used by our curriers and leather-dressers for the skins of oxen, or other beasts, when fresh, and covered with the hair: such as they receive them from the *slaughter*-houses where the butchers flea the carcase.

SLEDGE (*Cycl.*)—SLEDGE is a large smith's hammer, to be used with both hands: of this there are two sorts, the *uphand-sledge*, which is used by under workmen, when the work is not of the largest sort; it is used with both the hands before, and they seldom raise it higher than their head. But the other, which is called the *about-sledge*, and which is used for battering or drawing out the largest work, is held by the handle with both hands, and swung round over their heads, at their arm's end, to strike as hard a blow as they can.

SLEDGE, among miners. See DIGGING.

SLEEPERS, in natural history, a name given to some animals which *sleep* all the winter: such are bears, marmotes, dormice, bats, hedge-hogs, swallows, &c. These do not feed in winter, have no sensible evacuations, breath little, or not at all, and most of the viscera cease from their functions. Some of these creatures seem to be dead, and others to return to a state like unto that of the fœtus before birth. In this condition they continue, till by length of time maturating the process, or by new heat, the fluids are attenuated, the solids stimulated, and the functions begin where they left off. See Dr. Stevenson in Med. Ess. Edinb. Vol. 5. Art. 77.

SLEEPERS, in the glass trade, are the large iron bars crossing the smaller ones, and hindering the passage of the coals, but leaving room for the ashes. *Neri's* Art of Glass, Appendix.

SLEEPERS, in a ship, timbers lying before and aft in the bottom of a ship, as the rung-heads do: the lowermost of them is bolted to the rung-heads, and the uppermost to the futtocks, in order to strengthen and fasten the futtocks and rungs.

SLICH, in metallurgy, the ore of any metal, particularly of gold, when it has been pounded, and prepared for farther working. The manner of preparing the *slich* at Chremnitz, in Hungary, is this: they lay a foundation of wood three yards deep, upon this they place the ore, and over this there are four and twenty beams, armed at their bottoms with iron; these, by a continual motion, beat and grind the ore, till they reduce it to powder: during all this operation, the ore is covered with water. There are four wheels used to move these beams, each wheel moving six; and the water, as it runs off, carrying some of the metalline particles with it, is received into several basons, one placed behind another;

and finally, after having paffed through them all, and depofited fome fediments in each, it is let off into a very large pit, of almoft half an acre of ground; in this it is fuffered to ftand fo long, as to depofit all its fediment, of whatever kind, and after this it is let out. This work is carried on day and night, and the ore taken away, and replaced by more, as often as occafion requires. That ore which lies next the beams, where it was pounded, is always the cleaneft, or richeft.

When the *flich* is wafhed as much as they can, an hundred weight of it ufually contains about an ounce, or perhaps but half an ounce of metal; which is not all gold neither, for there is always a mixture of gold and filver, but the gold is in the largeft quantity, and ufually is two thirds of the mixture: they then put the *flich* into a furnace with fome lime-ftone, and flaken, or the fcoriæ of former meltings, and run them together. The firft melting produces a fubftance, called *lech*; this lech they burn with charcoal, to make it lighter, to open its body, and render it porous, after which it is called *roft*; to this roft they add fand in fuch quantity as they find neceffary, and then melt it over again. They have at Chremnitz many other ways of reducing gold out of its ore, but particularly one, in which they employ no lead during the whole operation; whereas, in general, lead is always neceffary, after the beforementioned proceffes. See the article GOLD-*ore*.

SLING (*Cycl.*)—SLING, at fea, a word ufed varioufly. There are *flings* to hoife up cafks, or any other heavy things; which are made of ropes fpliced into themfelves at either end, with an eye big enough to hold the thing to be *flung*.

There are other *flings*, which are made longer, and with a fmall eye at each end; one of which is put over the breech of a piece of ordnance, and the other eye comes over the end of an iron crow, which is put into the mouth of the piece, to weigh and hoife the gun as they pleafe.

There are alfo *flings* for the yards; which is done by binding them faft to the crofs-tree aloft, and to the head of the maft, with a ftrong rope or chain, that if the tie fhould happen to break, or to be fhot to pieces in fight, the yard, neverthelefs, may not fall down upon the hatches.

SLINGING (*Cycl.*)—SLINGING *a man overboard*, in order to ftop a leak in a fhip, is done thus: the man is truffed up about the middle in a piece of canvafs, and a rope to keep him from finking, with his arms at liberty, a mallet in one hand, and a plug, wrapped in oakum and well tarred in a tarpawling clout, in the other, which he is to beat with all difpatch into the hole, or leak.

SLOANEA, in botany, the name of a genus of plants, defcribed by Linnæus and Plumier, the characters of which are thefe. The perianthium confifts of one leaf, divided into feven fegments. There are no petals. The ftamina are a great number of flender filaments, broader at the end than in any other part, and of the length of the cup. The antheræ grow to the fides of thefe filaments. The germen of the piftil ftands in the bottom of the cup. The ftyle is fubulated, and longer than the ftamina. The ftigma is acute. The fruit is a large roundifh echinated capfule, compofed of four valves. The feeds are oval, obtufe, and flefhy, and have oblong nuclei. *Linnæi* Gen. Plant. p. 242. *Plumier*, p. 15.

SLOATH, in natural hiftory, the name of an animal remarkable for its flow motion. This creature is fo very tedious in all its motions, that it will be three or four days in climbing up, and coming down a tree, and does not go the length of fifty paces upon even ground in a day. The found of its voice feems only to exprefs the word *haii*, for which reafon the Brafilians call him by that name; but he ufually repeats the found about fix times together, defcending, as if one fhould fing, *la*, *fol*, *fa*, *mi*, *re*, *ut*. Whatever he takes hold of, he does it fo ftrongly, or rather fo ftiffly, that he will fometimes fleep fecurely while he hangs at it. *Bartæus*, de Reb. Braf. p. 222.

Clufius, Margrave, Pifo, and others, have given defcriptions of this animal, but they none of them mention the length of his fore feet; which, according to the animal preferved in the Mufeum of the Royal Society of London, is double that of the hinder pair. *Grew*'s Muf. p. 11.

From the fhag of his body, the fhape of his legs, and his having little or no tail, as alfo from the flownefs of his gate, and his climbing up trees, as little bears ufe to do, he feems to come near the bear-kind; from which he differs chiefly, in having but three claws upon a foot. This creature breeds principally in Florida and Brafil. Id. ibid.

SLOATS *of a cart*, the underpieces which keep the bottom of the cart together. See CART.

SLOE, *prunus fylveftris*, the Englifh name for the wild plum. See the article PRUNUS.

SLOE-*worm*, in natural hiftory, the name of an infect found on the leaves of *floe*, or black-thorn, and fometimes on thofe of the garden-plum.

This, and a like worm, found on the leaves of the oak, both remarkable for the hairs which cover them, each of which is forked or divided into two at the ends, are ufually efteemed caterpillars, but they are in reality animals of a very different clafs; the caterpillar has, at the utmoft, but fixteen legs, thefe have each twenty two, and have all the other characters of that clafs of infects, called by the French naturalifts *fauffes-chenilles*, or baftard-caterpillars.

All the animals of that clafs are very remarkable for the different figure they make after the laft change of their fkins, but this is in none feen fo obvioufly, as in thefe two fpecies; that of the oak is of a greenifh colour, and its hairs, which are fo ftiff that they almoft deferve the name of fpines, are black: that of the *floe* is of a greyifh hue, and its fpines longer, and of a deep brown; every one of thefe is, toward the extremity, divided into two, in the manner of the tines of a fork. Thefe give the animal a very remarkable figure, and are caft off with the feveral fkins, while the new fkins leave others in their place; but in the laft change, before that into the nymph ftate, the change made into the creature is fuch, that it could never be fufpected to be the fame animal by any one, who was not an eye-witnefs of the change.

The creature in this, throwing off its fkin, becomes perfectly fmooth, and of a dirty yellowifh colour, with not the lighteft variegation on it, nor the leaft appearance even of the remains of the fpines. In this ftate it remains till it goes into the nymph ftate, and from that, after about fixteen days, it comes out in the fhape of a four-winged-fly. The whole procefs of the change is the fame, in the two fpecies of the oak and the *floe*, but the flies they produce are very different. *Reaumur*'s Hift. Inf. Vol. 9. p. 119.

SLOT, (*Cycl.*) in the fportfman's language, a term ufed to exprefs the mark of the foot of a ftag, or other creature proper for the chafe, in the clay or earth, by which they are able to guefs how long the creature has been gone by, and which way he went. The *flot*, or treading of the ftag, is very nicely ftudied on this occafion: if the *flot* be large, deep printed in the ground, and with an open cleft, and added to thefe marks, there is a large fpace between mark and mark, it is certain that the ftag is an old one. If there be obferved the *flots*, or treadings of two, the one long, and the other round, and both of one fize, the long *flot* is always that of the larger beaft. There is alfo another way of knowing the old ones from the young ones by the treading; which is, that the hinder feet of the old ones never reach to their fore feet, whereas thofe of the young ones do.

Old ftags alfo are long jointed, and they never tread doubly, or falfely, as the young ones do, becaufe the tendons, that hold the joints of their feet, are ftronger; but the feet of the young ones are fometimes forced, for want of thefe ftrong finews, to turn away double. It is to be obferved alfo, that there is a great difference between the *flot* of a ftag or hart, and that of a hind; for there is no hart of the fecond head fo young, but that he leaves a larger and wider *flot* than the hind, excepting when the hinds are big with young, for on that occafion their claws will open as wide as thofe of the hart.

Another method of knowing the age of a ftag is by his fumets, though fome general rules are to be known, before any thing can be judged from this article. Thefe are, that in April and May, they caft their fumets, as it were, in cakes, and in June and July they caft them in thin, long, and large crotels, and from thence to the end of Auguft they hold the fame form and fize; but they are in this laft month always hard and knotty. In all thefe cafes, the largeft and longeft fumets are efteemed to be the marks of the largeft and oldeft ftags. If they have been difturbed, or if they have received any hurt, they ufually caft them fharp at one end, and dry. This alfo is conftantly the cafe, when their new horns are juft grown to their hardnefs, and they rub them againft the trees to get off the cracked membranes, which were the velvetings in their firft ftate. There is always alfo a difference between the fumets of the morning and thofe of the evening: thofe made at night, when they go to relief, are better digefted, and confequently moifter than thofe made in the morning, becaufe having taken their reft all day, there is a more perfect digeftion made than can be in the night, as they are, during that time, feeking food.

There are alfo feveral other ways of judging of the growth and fize of a ftag, as by his carriage, or bearings, according to the huntfman's phrafe; that is, according to the breaking of the tender branches of trees which he makes with his horns in paffing through. When the boughs are found bruifed and broken very high, and to a good width, there is no doubt of his being an old one: but this judgment is not to be made in the months of March, April, May, and June, becaufe their horns are at that time either wholly wanting, or they are young and velvety. The heighth of the creature's entries into the woods is alfo another mark of his fize, for the old ones are always proud and ftately, and go in erect, but the young ones will creep.

The older the ftag is the fooner he goes to fray, and the larger are the trees he choofes for this ufe; the young ones go later to it, and always choofe the weaker and lower trees. Notwithftanding that, after the fixth year, the age is not certainly known by the horns, as there is, after this time,

time, no increafe in the number of their branches, yet a probable guefs may be made from their being all thicker and more robuft, and the tops more open.

SLOUGH (*Cycl.*)—SLOUGH-*filver*, in our old writers, a rent paid in fome places in lieu of certain days work in harveft, heretofore referved to the lord from his tenants. *Blount.*

SLOW (*Cycl.*)—SLOW-*worm*, the Englifh name of the *cæcilia*, called alfo the *blind-worm*, and by fome the *deaf-adder*. See the article CÆCILIA.

SLUDS, a term ufed by the miners in Cornwall for half-roafted ores. See the article ORE.

SMALL (*Cycl.*)—SMALL-*craft*, in the fea language. See the article CRAFT.

SMALL-*pox*. See the article POX.

SMALL-*ftones*, among jewellers, denote diamonds under the weight of a carrat. *Jeffreys* on Diamonds, p. 21.

SMALL-*work*, among jewellers, is ufed to denote the ftar and fhell-facets of diamonds. *Jeffreys* on Diamonds. See the article FACETS.

SMALLAGE, in botany, &c. See APIUM.

SMALT (*Cycl.*)—There is not a more precarious procefs in all metallurgy, than the preparation of this fine blue glafs from cobalt, nor any manufacture, in which fo expert workmen are neceffary. The carrying the heat to too great a degree, in the roafting the cobalt, is a very mifchievous error, and the fuffering as much of the arfenic, as may be, to remain in the earth, is greatly to the advantage of the *fmalt*; and its colour may be greatly heightened, by adding common arfenic to it while it is in fufion.

It is always neceffary to make careful and repeated experiments on a new ore, or a kind of cobalt, which has not been worked before; by trying it with various degrees of heat in the roafting, and with different proportions of the flints and pot-afh in the fufion. On comparing the feveral products of thefe experiments, it will eafily be feen which yields the fineft colour, and this muft be always after followed in the great operations.

It is well known that the beautiful blue glafs, called *fmalt*, is prepared from the fixed earth of cobalt; but experiments have proved, that this earth alone will not acquire that fine colour. Dr. Link tried fome of it, by keeping it eight hours in the moft intenfe heat, yet on taking it out, it was only a grey glafs, excepting that there were a few blue fpecks in it near the edges of the crucible. Thefe fpecks make no objection to this doctrine, when properly confidered; for they were owing, doubtlefs, to the fame fubftance which is found neceffary to be ufed, in order to procure the blue colour.

Flints are the neceffary addition to cobalt for the making the blue glafs, or *fmalt*, and the crucible being made of earth, might eafily contain fome particles of fand. Every piece of fand is a fmall ftone, of the nature of flint; that is, a piece of cryftal debafed by earth; and thefe fmall flints mixing with the glafs of the cobalt-earth, while in fufion, rendered the fmall fpecks, where they were mixed, true *fmalt*, while the reft remained grey and unaltered.

This earth of cobalt evidently contains fome portion of copper, though fo fmall in quantity, that it can never be difcerned by the common figns, and fo intimately blended with the earth, that it can never be procured feparate. The lightnefs of this earth alfo, in which the copper refides after the fublimation of the arfenic, is a proof that its quantity muft be very fmall; yet that it exifts there, is evident from the colours it affords.

Copper is well known to yield a green colour with acids, and a fine blue with alkalies. Thus a folution of this earth in aqua fortis is of a deep green, and its glafs, when mixed with the alkali of flints and of pot-afh, is the fine deep blue *fmalt*: nor is it wonderful, that the vitrified earth of cobalt will never become blue by calcination alone, fince, if it owes this colour to copper, it cannot be fuppofed to fhew itfelf till called forth by an alkali. Philof. Tranf. N° 396. p. 201.

Some cobalt yields *fmalt* before roafting, even better than it would afterwards; this is a peculiar kind of cobalt, but is fo like the reft, that it cannot be diftinguifhed by the eye, but experiment alone fhews this property in it. Though cobalt in general requires roafting, in order to fit it for yielding the *fmalt*, yet its different kinds require fome more, and fome lefs roafting; and the degree can never be judged of by the infpection of the mineral, but is only known by the experienced artift in the procefs. Hence it is, that expert and intelligent perfons are neceffary in the *fmalt*-works more than in almoft any other branch of this fort of bufinefs.

The addition of a fmall quantity of arfenic, or of the arfenical flowers, during the time that the *fmalt* is in fufion, adds greatly to the beauty of the colour: this is a practice kept fecret by the workmen of fome places; and by this means their *fmalt* is always rendered better than that of their neighbours. It is eafy to fee from this, that the roafting of the cobalt is the neceffary beginning of the *fmalt*-work, not the divefting it of its arfenic, which only happens accidentally in that procefs; and it would be much better if it did not happen, fince we find the arfenic added afterwards exalts the colour. From hence it is evident, that thofe cobalts which will make *fmalt* without previous roafting, muft, as they are found to do, make the very fineft *fmalt*, becaufe their arfenic is yet left in them in great part: and from this alfo appears the neceffity of having expert workmen for the *fmalt*-making; fince the knowing the degree of fire neceffary to the ore is a moft effential article; and after the roafting has been carried to a fufficient degree, every moment's heat divefting it of more of its arfenic than was neceffary, makes the colour of the *fmalt* to be made afterwards fo much the worfe. From this alfo appears the reafon why the blue, made by precipitation from a folution of cobalt, is fo much fuperior to the common *fmalt* made by fire; becaufe in this the arfenic is all preferved, whereas, in the common way of preparing it by fire, it is driven off. Philof. Tranf. N° 396.

SMARAGDUS, the *emerald*, (*Cycl.*) a very beautiful gem of a fine green colour.

The gem known by the antients under the name of the *fmaragd*, or *emerald*, was the fame with that we call at this time by the fame name, which has not been the cafe in the hyacinth, fapphire, and many others.

In the days of Pliny we find, however, that a great deal of error and confufion had crept into the world in regard to this gem, that author giving a long lift of the different kinds of *emeralds*, as he calls them; among which there are evidently jafpers, coloured cryftals, and fpars, reckoned among the fpecies of this gem.

Our jewellers know only what they call two fpecies of the *emerald*, the Oriental and the Occidental, and fuch there are without queftion; that is, the *emeralds* of the Eaft-Indies are, in their pureft ftate, much finer than thofe of any other part of the world, as is the cafe in the other gems: but our jewellers feldom meeting with thefe fine ftones, call the American *emeralds* Oriental, and ufually fell cryftal, accidentally tinged green, under the name of *Occidental emeralds*. Thefe laft being alfo greatly more common than the others, there has grown an opinion among our lapidaries, that the *emerald* is no harder than cryftal; and this has no other foundation, than their ufually meeting with cryftal under the name of the *emerald*.

The genuine *emerald*, when in its moft perfect ftate, is perhaps the fineft and moft beautiful of all the gems. It is found of various fizes, but ufually fmall. Multitudes are met with of about the fixteenth of an inch in diameter, and they are found from this up to the fize of a wallnut. We have accounts of fome of immenfe fize among the antients; but they were evidently not *emeralds*, but jafpers, or other green ftones. The large fpecimens at prefent are very fcarce, and whether they are Oriental or Occidental, are of very great value. *Hill's* Hift. of Foff. p. 596.

The *emerald* is naturally of different figures, like the diamond, and many of the other gems. It is fometimes found in a roundifh, or pebble-like form, but much more frequently in a columnar, or angular one, refembling common cryftal. The pebble *emeralds* are always the hardeft and brighteft, but are feldom found exceeding the fize of a pea, very rarely coming up to that of a horfe-bean. The cryftalliform ufually grow feveral together, and are often confiderably large. The pebble *emeralds* are found loofe in the earth of mountains, and in the fands of rivers; the columnar are ufually found adhering to, or bedded in a white opake cryftalline matter, and fometimes to the jafper, or to the prafius; which laft has been therefore called by fome the mother of the *emerald*.

The rough *emerald*, of whatever form, is ufually of a very bright, and naturally polifhed furface, and is ever of a pure and beautiful green, without the leaft admixture of any other colour. It is of all the various fhades of green, from the deepeft to the paleft, and doubtlefs is fometimes wholly colourlefs; but it is then efteemed a fapphire, all the harder gems, when colourlefs, being called by our jewellers *white fapphires*.

The Oriental *emerald* is of the hardnefs of the fapphire and ruby, and is fecond only to the diamond in luftre and brightnefs; the American is of the hardnefs of the garnet; and the European is ftill fofter than that, but confiderably harder than cryftal; yet the coloured cryftals, ufually fold under the name of *emeralds*, have very much debafed the credit of this gem. It lofes its colour in the fire, and becomes undiftinguifhable from the white fapphire.

The Oriental *emeralds* are very fcarce, and are at prefent found only in the kingdom of Cambay: very few of them have of late been imported into Europe, infomuch, that fome have fuppofed that there were in nature no Oriental *emeralds*; but within thefe few years fome have been brought from Cambay into Italy, which greatly exceed all the American ones in beauty, as well as hardnefs.

The American *emeralds*, which, as they are the fineft that come to us, are called by our jewellers *Oriental*, are found principally about Peru, in the earth of fome mountains. The European *emeralds* come principally from Silefia, though there are of them in other places; and the coloured cryftals,

which are what we usually meet with under the name of *Occidental emeralds*, are from the mines of Germany.

The scarcity of *emeralds* from the East-Indies has so generally confirmed the opinion of there being none there, that the most skilful of our dealers in gems generally tell us, that there is no such stone as an Oriental *emerald*, but that the fine ones are all from Peru; and Tavernier supposes that many *emeralds*, which, in the memory of the jewellers in his time, had certainly been brought from the East-Indies, were originally brought from Peru; and to support this, he gives us an account of the Peruvians trading by the South-Sea to the East-Indies before the Europeans discovered America: but this is a far-fetched conjecture, as no footstep of such a trade subsists. The truth, in regard to the present scarcity of the Oriental *emeralds* with us, seems to be this; that though the people of the East-Indies were once in an humour to part with their *emeralds*, they have since chose to keep them in their own hands; as it is well known to travellers, that the princes of the East are at least as well acquainted with the value of gems as we, and are willing to purchase those, which are not of the produce of their own country, at as great a price. *Hill's* Hist. of Foss. p. 597.

SMARIS, in zoology, the name of a small fish caught in the Mediterranean, and common in the markets of Rome, Venice, and elsewhere, and sold to the poorer sort of people at a very small price.

It is seldom of more than a finger's length, and of a round, not flatted body, of a dusky blackish green on the back and sides, and not marked with any variegations, but having on each side, near the middle of the body, one large black spot. Its gill-fins and tail are of a faint red. The iris of the eyes is of a brownish white, and the tail is forked. *Gesner*, de Pisc. p. 616.

SMATCH, in zoology, a name by which the common œnanthe is called in many parts of England. See the article OENANTHE.

SMECTIS, in natural history, a name used by several authors for the common fuller's earth, more commonly called *cimolia purpurascens*. *Hill's* Hist. of Foss. p. 49. See the article FULLER'*s earth*.

The *fuller's earth* of England is a much more valuable article of commerce, than many would believe. It has the property of imbibing oil or grease, or any other fat substance; and the great use that is made of it, is for the cleansing of woollen-cloth. Every one knows, that tar is often employed in the external distemperatures of sheep, as are also tallow, grease, and many other fatty and unctuous substances. The wool itself, after shearing, cannot be worked up without being first oiled, or greased. For these, and many other reasons, all our woollen-cloth must necessarily be greased, but then all this grease must necessarily also be taken out of it again, before it can be sold or worn, and nothing yet known serves to this purpose so well as this *earth*.

The *fuller's earth* is very plentiful in England, and as much excels that of all other nations in goodness, as in quantity and cheapness, and this is one great reason why we have the advantage of other nations in the woollen manufacture; to preserve and secure this to us, the *fuller's earth* is forbid to be exported, under large penalties, by Act of Parliament. This *earth* is one great instance of the value of the English fossils; and Dr. Woodward's love for his native country has carried him so far, as to make him affirm, from his own observation, that this island wants no fossile substance known in the world, except diamonds, and some other gems, and quicksilver ores. *Woodward's* Cat. Foss. Vol. I. p. 8.

SMEGMA, a kind of wash in use among the antients. See the article DETERSORIUM.

SMELL, (*Cycl.*) is used as the name of a peculiar sort of wine, of which there are two species; the one sort is very fragrant, muscatelline, and aromatic; this is called simply the *smell-wine*: but the other, which is very rank and offensive to the nose, is called by the Germans *smel-bruntzer*. Many have been the conjectures about the occasion of the rank smell of this wine, it not being owing to the grape it is made from, those of the same vineyard often affording the aromatic, and often the rank wine: some have imputed the strange difference to the vessel, others to the vine, and others to the earth it grows in; but the first of these is too trifling a cause for such an effect, and the others are confuted by experience of the same vine, in the same place, yielding both. The opinion of Portzius, that the rankness of the *smell* of some of this wine is owing to some irregularities in the working; this is certain, that it never is perceived before the working. The *smell* is truly urinous, and is that of a volatile alkali; which not being embodied in, or subdued by the acid of the grape in this imperfect fermentation, shews itself in this rank manner. It is evident that the *smell* is of a volatile nature, for it is often lost in the drawing the wine several times out of one vessel into another, evaporating during the time of the drawing it out. *Portzius*, de Vin. Rhen.

SMELLING (*Cycl.*)—The sense of *smelling* seems extremely fine in some insects. It is reported of bees, that they will smell honey or wax above a mile; and on this quality, in that little creature, is founded a very profitable sort of hunting in the woods in New-England, and some other places, for the honey which the wild bees collect. These insects are very numerous in the woods there, and have great stores of wax and honey; but it was always very difficult to find them, till this method was invented.

The hunter always chooses for his purpose a fine, clear, and sun-shiny day: he then goes out into the woods with a trencher in his hand, on which there is some honey; this he sets down upon the stump of a tree. The bees soon find this out, and come to feed on it: as soon as three or four are come about it, he catches them severally in little boxes, and after a few minutes he lets them out one by one, and observes their course. The creature always mounts to a little height in the air, and then goes directly forward in a strait line to the tree in which the hive is. As the hunter cannot pursue this little creature in her flight through a thick wood, he always takes with him his pocket-compass, rule, and other instruments, with a sheet of paper, and on this he sets down the course; suppose it, for instance, to be west. By this he is certain, that the tree where the hive is must be somewhere in a line due west from the place where he is; but he wants to know the exact distance from his station. In order to do that, he makes an off-set, either south or north, suppose north, of an hundred perches, or rods; if it be more, it will be still more exact, because the angle will not be so acute. Then he goes to this second station, and lets out another bee, and observes its course also very carefully; for being loaded it will certainly, after mounting to a small height in the air, fly directly to the hive as the former did. This second course the hunter finds to be south fifty four degrees west; then there remains nothing but to find out where the two courses intersect, for in that place the tree, and the hive in it, certainly is.

The foundation of all this, is the strait or direct motion of bees, which, when loaded with honey, always fly directly to their hive; and this is found to be an unalterable law of nature in these animals, so that the hunter is never disappointed, when he takes his measures rightly, and vast quantities of honey are thus taken every year.

One very remarkable part of this history is, that though the bees are now so vastly plentiful in this part of the world, they are not natives there, and are only the produce of such bees as were carried thither from England about an hundred and fifty years ago: for the first planters never saw a bee in the woods till long after the place was settled, and hives of bees, among other things, had been brought from us. What is a greater proof of this, is, that the natives of the place knew nothing of the bee till they saw ours; they have no word in their language to express that creature, but commonly called it, for a long time, the *Englishman's fly*. Before this method of finding the hives was brought into practice, the planters used to watch the bees which they found in the woods by the eye, and after observing several, one after another, fly the same way, they would sometimes hit upon the place; but it was with great uncertainty, as well as great difficulty. It is observed of the bees in that part of the world, that in swarming they never move northward, but always either due south, or something inclining that way. Philos. Trans. N° 367.

SMELT, *apua phalerica*, in ichthyology. See APUA.

These fish will live almost any where, but they are very apt to degenerate. They are common in the rivers of New-England, and are as large as with us, often weighing two ounces and a half; but a pail-full of these being taken from one of their rivers, and put into an adjoining pond, they all degenerated in such a manner, that they were afterwards found so small, that the largest did not weigh more than five pennyweights. Though thus small, however, they are much valued, and are better tasted than the others. They are very transparent, and of a beautiful shining pearl colour. Philos. Trans. N° 374. p. 232.

They are called *smelts*, because they melt, as it were, or dissolve between the fingers in handling them.

SMELT, among the fishermen in Yorkshire, and some other parts of England, is also a name given to the salmon while in its first year. *Willughby's* Hist. Pisc. p. 189. See the article SALMON.

SMELTING (*Cycl.*)—SMELTING-*house*, a house where they run and melt the ore into lead; one of these will run a ton in ten or twelve hours; a fodder is their usual day's work, that is, twenty two hundred and an half weight. *Houghton's* Compl. Min. in the Explan. of the Terms.

SMEW, in zoology, the English name of the common mergus, known among authors by the name *albellus*, and *mergus cirratus*. See MERGUS.

SMILAX, in botany, the name of a genus of plants, the characters of which are these. The flower is of the rosaceous kind, being composed of several petals arranged in a circular form. The pistil finally becomes a soft roundish berry, containing a roundish or oval seed.

The species of *smilax*, enumerated by Mr. Tournefort, are these. 1. The rough *smilax* with red berries. 2. The rough *smilax* with fewer prickles, and with black fruit. 3. The

rough *ſmilax* with broad and blunt-pointed leaves, and no notches or prickles at their edges. 4. The one-leaved dwarf *ſmilax*, called *one-leaf*, *unifolium*, and *little lilly of the valley*. 5. The rough racemoſe *ſmilax* with Solomon's ſeal leaves. 6. The ſpiked *ſmilax* with Solomon's ſeal leaves. *Tourn.* Inſt. p. 654.

SMILAX *aſpera*, is uſed for great ſcarlet oak, or ilex. *Tourn.* Inſt. p. 553.

SMILAX *lævis*, in botany, a name given by many authors to our common great white bind-weed. See the article CONVOLVULUS.

SMIRIS, in natural hiſtory. See EMERY.

SMITING-*line*, in a ſhip, is a ſmall rope faſtened to the miſſen-yard-arm, below at the deck, and is always furled up with the miſſen-ſail, even to the upper end of the yard, and from thence it comes down to the poop. Its uſe is to looſe the miſſen-ſail without ſtriking down the yard, which is eaſily done, becauſe the miſſen-ſail is furled up only with rope-yarns; and therefore when this rope is pulled hard, it breaks all the rope-yarns, and ſo the ſail falls down of itſelf. The word of art is, *ſmite the miſſen* (whence this rope takes its name) that is, hale by this rope that the ſail may fall down.

SMOKE (*Cycl.*)—SMOKE-*ſilver*, in our old writers. Lands were held in ſome places by the payment of the ſum of ſixpence yearly to the ſheriff, called *ſmoke-ſilver*. Pat. 4 Edw. 6. *Smoke-ſilver*, and *ſmoke-penny*, are to be paid to the miniſters of divers pariſhes as a modus, in lieu of tithe-wood; and in ſome manors, formerly belonging to religious houſes, there is ſtill paid, as appendant to the ſaid manors, the antient Peter-pence, by the name of *ſmoke-money*. *Blount.*

SMORZATO, in the Italian muſic, is uſed to ſignify that the bow, or fiddle-ſtick, ſhould be drawn to its full length, not with the ſame ſtrength of hand throughout, but bearing lighter and lighter on it by degrees, till at laſt ſcarce any ſound be heard. This term is not much uſed at preſent. *Broſſard.* Dict. Muſ.

SMUT (*Cycl.*)—SMUT, in huſbandry, a diſeaſe in corn, in which the grains, inſtead of being filled with flower, are full of a black ſtinking powder.

Many things have been ſuſpected as the cauſes of this diſtemperature in corn; but Mr. Tull ſeems convinced by experiment, that it is cauſed only by too much moiſture, the ſeveral plants of corn, which he had taken up by the roots and planted in troughs of very moiſt earth, all bringing forth *ſmutty* ears, while very few ſuch were found in the corn of the field from whence theſe plants were taken. It is obſervable, alſo, that thoſe ears, the grains of which are to be *ſmutty*, never ſend up any flowers at all.

The two things, recommended by writers of huſbandry as remedies, or preventions of this diſeaſe, are brining, and changing the ſeed. The firſt of theſe methods was accidentally diſcovered about a century ago: a ſhip load of wheat was, about autumn, ſunk near Briſtol, and afterwards was taken up at the ebbs at ſeveral times, after being thoroughly ſoaked in ſea-water. When the wheat was all taken up, it was found unfit to make bread of, but a farmer trying ſome of it for ſowing, found it anſwer very well, and himſelf, and the neighbouring farmers, bought it all up at a ſmall price; the country all about was ſown out of this cargo. It happened that *ſmuttyneſs* in the wheat-corn was a reigning diſtemper in all parts of the kingdom at that time, but it was remarkable, that all the fields ſown with this ſalt wheat were abſolutely free from the miſchief: this eaſily introduced the practice of ſoaking wheat, before ſowing, in a brine of ſalt and water, to prevent it in other places, and it has ſucceeded well. Mr. Tull gives an inſtance of the certainty of its effect, in the caſe of two farmers whom he perſonally knew, and whoſe farms lay intermixed: theſe men bought the ſame ſeed between them from a very good change of land, and parted every land between them in the field; the oldeſt farmer believed the brining to be a fancy, and ſowed his ſeed unbrined, the other brined all his ſeed, and the conſequence was, that the old farmer had a great deal of *ſmut* in his corn, while the other had not one *ſmutty* ear.

When wheat is intended for drilling, it muſt be ſoaked in no other brine than that of pure ſalt and water, for if there be any greaſe among it, it will never be dry enough for this manner of ſowing. If ſeed wheat be ſoaked in urine, it will not grow, and if it be only ſprinkled with it, it will moſt of it die, unleſs it be planted preſently. The moſt expeditious way of brining wheat for drilling, is to lay it in a heap, and waſh it with a ſtrong brine ſprinkled on it, ſtirring it up with a ſhovel, that it may be all equally brined, or wetted with it; after this ſift on ſome fine lime all over the ſurface, and ſtir it up, ſtill ſifting on more in the ſame manner till the whole is duſted with the lime, it will then be ſoon dry enough to be drilled without farther trouble. It muſt be quick lime, in its full ſtrength, that is uſed on this occaſion.

Bad years will cauſe *ſmut* in corn, and good years will prevent it: it is, however, obſervable, that the crops in which there is *ſmutty* corn will, if uſed for feed, be liable to produce *ſmutty* corn again, rather than other ſeed. The brining is a defence againſt bad years, and againſt the miſchiefs attending the ſowing corn among which there has been *ſmut*.

The other method of changing the ſeed is by many held effectual to prevent *ſmuttyneſs* in the crop; ſeveral, who have tried this with due care, have found perfect ſucceſs from it: and it is to be obſerved, as to the great ſucceſs of the drowned wheat at Briſtol, that it was a change of ſeed to the lands on which it was ſown, as well as a brined ſeed.

Seed-wheat ſhould be bought from the crop on a ſtrong clay-land, whatever kind of land it is to be ſowed upon. A white clay is a good change for a red clay, and a red clay for a white; but whatever the land be, from which the ſeed is taken, it may be infected, if that be not changed there the preceding year; and then there may be danger, though it be had from ever ſo proper a land. It is a rule among the farmers, never to buy ſeed-wheat from a ſandy ſoil; they expreſs their diſlike of this by the coarſe rhime; *ſand* is a change for no *land*.

A crop of wheat, very early planted, is not ſo apt to be *ſmutty*, as one planted leſs early; and the farmers have obſerved, that the largeſt and plumpeſt ground fat wheat is more liable to be *ſmutty* than the ſmall ground wheat. *Tull's* Horſehoeing Huſbandry.

The *ſmut* of corn uſually happens after rain, followed by a bright ſunſhine; and when the *ſmutted* ſtalks are examined, they are found to be ſpotted, and pricked as it were with ſmall burnt places. The cauſe of the malady, therefore, probably is, that thoſe ſmall drops of rain, which remain upon the ſtalks before they are dried up by the ſun, act as ſo many lenſes, or ſmall burning-glaſſes, and their focus being very near them, their effect falls upon the ſtalk which ſupports them; wherefore the ſun's rays, collected in this point, muſt burn, and this burning dries up the ſtalk, and prevents the ear from graining, or producing its proper ſeeds. See the article BLIGHT.

Smutty corn is of a very miſchievous nature to thoſe who eat it. Schober has publiſhed a diſſertation on a terrible epidemical malady that raged, in the year 1722, in many parts of Germany, and carried off a great many people of all ages and ſexes: this he attributes wholly to their eating flower and bread made of corn, among which a larger than ordinary quantity of this *ſmut* had been produced the year before, and ground down with it. From this it appears, that theſe black ears have a ſtupefactive and narcotic quality, depending on a peculiar ſulphur they are endowed with, and to this ſulphur it is owing, that they are ſo inflammable beyond other corn. This ſulphureous principle is very hurtful to the nerves, and never fails to cauſe diſorders of them, of various kinds, when taken in any quantity; contractions, and convulſions of the limbs, vertigos, ſleepineſs, and, in fine, light-headedneſs, were the ſymptoms of the diſeaſes brought on by the eating it on the occaſion abovementioned; and ſometimes true, and incurable epilepſies come on. Some were ſeized with fevers, and children in particular were found more ſubject to the ſmall-pox that year, than they had been obſerved to be, and they had commonly very bad kinds.

SMYRHIZA, in botany, a name uſed by Pliny, and ſome other of the old authors, for the common myrrhis, or chervil. *Ger.* Emac. Ind. 2.

SMYRNIUM, *Alexanders*, in botany, the name of a genus of the umbelliferous plants, the characters of which are theſe. The flower is of the roſaceous kind, conſiſting of ſeveral petals, arranged in a circular order on a cup, which afterwards becomes a fruit of a ſort of globular figure, compoſed of two thick and, in ſome degree, lunated ſeeds, being gibboſe and ſtriated on one ſide, and flat and ſmooth on the other. See Tab. 1. of Botany, Claſs 7.

The ſpecies of *ſmyrnium*, enumerated by Mr. Tournefort, are theſe. 1. The common great *ſmyrnium*, or herb *Alexanders*. 2. The round-leaved Candy *ſmyrnium*. 3. The leſſer parſley-leaved Portugal *ſmyrnium*. *Tourn.* Inſt. p. 31.

The antient Greeks have plainly deſcribed two different plants under this name; the one the common *Alexanders*, the other the *petroſelinum Cilicium*, or Cilician parſley. The former of theſe plants loves moiſt and rich ground, and the other grows no where but on rocky hills, and in the drieſt and moſt barren places. Pliny, not obſerving that the antient writers knew two plants under this name, accuſes them of an error, in ſaying that the *ſmyrnium* loved dry and barren places, whereas the Romans, who cultivated the *ſmyrnium* at that time, found it delighted only in rich moiſt ſoils; but the antients, whom he cenſures thus, had ſpoke what he records of the *petroſelinum*, not of the great water-*ſmyrnium*.

SMYRUS, in ichthyology, a name ſometimes given by Pliny to the fiſh called by authors *myrus*, and by Willughby the *ſea-ſerpent* with a compreſſed tail.

It is a ſpecies of the muræna, according to Artedi, and is diſtinguiſhed from all the others by that author, under the name of the *muræna* with a ſharp ſnout, variegated with white

white spots, and with the edge of the back fin black. See the article MURÆNA.

SMYTHAM, in mineralogy, lead-ore stamped and pounded down, like powder or sand, to cleanse the stones and earth from the ore. *Houghton's* Compl. Miner in the Explan. of the Terms.

SNAFFLE, in the manege, a well known kind of bridle. The *snaffle*, after the English fashion, is a very slender bit-mouth without any branches: they are much used in England instead of true bridles, which are only employed in the service of war. The French call them *bridons*, by way of distinction from *brides*, i. e. bridles.

The *snaffle*, or small watering-bit, is commonly a scatch-mouth, accoutred with two little very straight branches, and a curb, and mounted with a head-stall and two long reins of Hungary leather.

SNAIL, in ichthyography. See LIPARIS *nostras*.

Perrault doubts of *snails* having eyes, and Dr. Brown denies it; but according to Dr. Porterfield, a good microscope shews them distinctly. Med. Ess. Edinb. Vol. 3. Art. 12.

The eyes of *snails* are lodged in their four horns, one at the end of each horn, which they can retract at pleasure. Id. ibid.

The manner of examining these eyes is this: when the horns are out, cut off nimbly the extremity of one of them, and placing it before the microscope, you may discover the black spot at the end to be really a semiglobular eye.

The dissection of this animal is very curious; for by this means, the microscope not only discovers the heart beating just against the round hole near the neck, which seems the place of respiration, but also the liver, spleen, stomach, and intestines, with the veins, arteries, mouth, and teeth, are plainly observable. The guts of this creature are green, from its eating of herbs, and are branched all over with fine capillary white veins. The mouth is like a hare's, or rabbet's, with four or six needle-teeth, resembling those of leeches, and of a substance like horn.

Snails are all hermaphrodites, having all each sex united in the individual; they lay their eggs with great care in the earth, and the young ones are hatched with shells compleatly formed.

Cutting off a *snail*'s head, a little stone appears, which is supposed to be a great diuretic, and good in all nephritic disorders. Immediately under this stone the heart is seen beating, and the auricles are evidently distinguishable, and are membranous, and of a white colour; as are also the vessels which proceed from them.

Snails discharge their excrements at a hole in their neck; they also breathe by this hole, and their parts of generation are situated very near it. The penis is very long, and in shape resembles that of a whale. *Baker's* Microscope, p. 217.

So small an animal as the *snail* is not free from the plague of supporting other smaller animals on its body; and as in other animals we find these secondary ones either living only on their surface, as lice, *&c.* or only in the intestines, as worms, it is very remarkable that this creature infests the *snail* in both these manners, being found sometimes on the surface of its body, and sometimes within its intestines.

There is a part of the common garden-*snail*, and of other of the like kinds, commonly called the *collar*; this surrounds the neck of the *snail*, and is considerably thick, and is the only part that is visible, when the animal is retired quietly into its shell. In this state of the animal these insects, which infest it, are usually seen in considerable numbers marching about very nimbly on this part: this nimble motion is almost peculiar to them, most other creatures of this kind being very slow in their motions: they may be seen in many other circumstances of the animal, but it is this in which they are most obvious to the naked eye. Though they are very small, they cannot however make their way under the shell, to run over the rest of the body of the *snail*, every part of it adheres too firmly to the shell to suffer that; but they have another very different way of enlarging their place of abode: the *snail*, every time it has occasion to open its anus, gives them a place by which to enter into its intestines, and they often seize the opportunity. The anus of this creature is situated not within the shell, but in this collar, which surrounds the mouth of it; and the *snail* seldom moves, to go a little way out of its shell, without opening it, as it does also in many other circumstances.

These insects always take advantage of the opening, and swiftly get in and run up into the intestines, insomuch that their natural residence seems there, and that they never are upon the surface of the animal but by accident, and much against their will; they seem to be driven thither by this accident: the fæces of the *snail* fill up the whole width of the intestine, and when they are discharged, must necessarily carry out with them whatever is between them and the anus; now it may easily happen, that a number of these small animals may be in that part of the intestine, which is between the anus and the fæces: all these must be discharged with them, and while they are walking about upon the neck of the animal, the aperture of the anus closes, and leaves them no power of entering back again, till another opportunity; and the frequency of this accident may easily drive out enough of these insects, to keep always some upon the neck, though every one of them, while there, is seeking the first opportunity of getting into the intestines again.

These insects infest every kind of *snail*, though they are most frequent on the common large garden-kind; but there is a small species of *snail*, remarkable for a sort of cover, nearly as hard as the shell, with which the creature closes up its mouth upon occasion: in this these creatures may be distinguished, even within the intestines. The skin of this *snail* is very thin and transparent; and if the shell be broken off a little way, and the eye kept attentively on that part, these little insects will be distinguished through the skin running nimbly about in the intestines.

Though these insects are found in all sorts of *snails*, they are not to be seen at all times; rainy seasons seem particularly disadvantageous to them, and it is only in dry times that they are always to be found when looked for; whether it be that the rain destroys the animals, when already formed, or that they are in themselves but short-lived, and the rain prevents the hatching of the eggs for more. The insects are content with the naked body of the *snail* alone as their habitation, they never get upon the shell, and if they are forced to it, they as soon as possible quit it again, and get to their old post. They appear of a whitish colour to the naked eye, some of a dirty greyish white, and some of a white with a mixture of reddishness; but a microscope is necessary to give us a view of their different parts and structure. They have a regular trunk, in the manner of many other insects, which they occasionally can bend downwards, and in a great measure hide from the sight: this trunk, which serves them to suck in their nourishment from the body of the *snail*, is placed between two little horns, which are extremely moveable every way, and are capable of being extended in length, or shortened, in the manner of the horns of the *snail*, which is a circumstance not observable in the horns, or antennæ of other insects. The body is divided into six rings, beside the anterior part, on which are placed the horns and the trunk. The creature has four legs on each side, two of which on each are articulated into the anterior part, which gives rise to the horns and trunk, and the other two into the first ring of the body; so that they stand in pairs, the second and third on each side being greatly more distant from one another than the first and second, or the third and fourth: these legs are all furnished with very long hairs, and seem to terminate, each in two or three points, in the manner of the legs of many of the beetles. The back is elevated into a convex form, the sides also are rounded, and each ornamented with three or four hairs; but there are none under the belly. Mem. Acad. Par. 1711.

Snails are great destroyers of fruit in our gardens, especially to the bitter sorts of wall-fruit. Lime and ashes sprinkled on the ground where they most resort, will drive them away, and destroy the young brood of them. It is a common practice to pull off the fruit they have bitten, but this should never be done, for they will eat no other till they have wholly eat up this, if it be left for them.

The Romans were fond of *snails*, and had them fed on purpose for their tables. Their taste is not delicious, but rather disagreeable; but this they disguised by means of good sauces, and had other reasons for the receiving them into the list of foods. They used them as provocatives, or inciters to venery, and with this intent they eat only the necks, as the part in which the parts of generation of the creature were placed; and they had the greater opinion of the efficacy of these, as the parts of generation were double in each individual, that is, the male and female parts both situated in the neck of every *snail*.

Aristotle, and the old Greeks, had no idea of the generation of these insects, in the manner of other animals, but supposed them produced spontaneously; but the Romans shew, by many passages in their writings, that they had got over this error, and even seem, by the preference they gave to the neck of this animal, in this intention to have understood the hermaphrodite structure of this insect, which much later ages have pretended to make a new discovery.

The Eastern nations at present run much into the opinions of the Romans of old, as to provocatives; they use, as the others did, every thing that serves to the purposes of generation in other animals, and every thing that has but the resemblance of the external figure of the parts subservient to it. The orchis roots, which resemble the testicles of animals in shape, and contain a white and slimy, or viscous liquor, have introduced themselves into use on this plan, and so of many other things. Phil. Transf. N° 50.

Oat-SNAIL, a name given by Dr. Lister, in the Philosophical Transactions, to a small *snail*, which he observed under the loose bark of old willows, elms, and others trees, and which is of a very singular structure; the shell resembling an oat-corn, whence the name, and its volutæ, or wreaths, running contrary to the direction of them in other *snails*, that is

is eaſt and weſt, as the philoſophers expreſs it, referring it to the motion of the ſun; but theſe ſhells, to uſe that language, have the turns weſt and eaſt, or more plainly, they have the turns running from the right-hand to the left, not from the left to the right as other ſnails. Philoſ. Tranſ. N° 250.

SNAKE, *(Cycl.) anguis.* See the article ANGUIS.

The poiſonous qualities of ſome of the *ſerpent*-kind, have given the generality of the world a diſtaſte to all of them, but our common *ſnake* is a harmleſs and inoffenſive animal, and might even be kept tame in our houſes, where it would deſtroy vermin, and never be of any hurt to any thing. This animal may be ſuppoſed as far from tameneſs in its nature, as any that could be thought of, yet, in the Acta Leipſienſia, we have an account of ſeveral which were kept tame in a houſe, and taught ſo far, as to go regularly into their boxes every night. The perſon, who diverted himſelf with keeping theſe, had the entertainment of ſeeing them change their ſkins ſeveral times, and of obſerving their laying their eggs, of which they would depoſit twelve or thirteen in the ſpace of half an hour. Act. Leipſienſ. Anno 1670.

That *ſnakes* are viviparous, ſee Philoſ. Tranſact. N° 8. p. 138.

SNAKE *with two heads*, a kind of *ſnake* in Braſil, having a ſwelling at its tail, which at a diſtance has the appearance of a head.

The Portugueſe call it *ſnake* with two heads; their fear of this creature, for the bite of which they pretend there is no remedy, having prevented their examining into the truth. They alſo pretend that it is dangerous to meddle with theſe *ſnakes* after they are dead, and that barely touching them will give the itch. Mr. Couplet was, notwithſtanding, bold enough to flea ſeveral of them, but found himſelf, after having performed this operation on two or three, all covered with puſtules filled with a reddiſh water. Theſe remained on him a conſiderable time, and he was not quite well in three months.

The country of Braſil abounds with large *ſnakes*, the bite of which is venomous; but the natives and blacks make no ſcruple of eating them. Mem. de l'Acad. des Scienc. 1700. p. 228, 229.

Blood-SNAKE. See the article HÆMORRHOUS.

Rattle-SNAKE. See RATTLE-*ſnake*.

Sea-SNAKE. See the article SERPENS *marinus*.

Spectacle-SNAKE. See COBRAS *de capello*.

SNAKE-*ſtone*, *ammonitæ*, in natural hiſtory, the name of a large genus of foſſile ſhells, very few, if any, of which are yet known in their recent ſtate, or living either on our own, or any other ſhores, ſo that it ſeems wonderful whence ſo vaſt a number and variety of them ſhould be brought into our ſubterranean regions. They ſeem indeed diſperſed in great plenty throughout the world, but no where are found in greater numbers, beauty, and variety, than in our own iſland. See SERPENT-*ſtones*.

They are of very different ſizes, as well as ſpecies, ſome being found of the ſize of a ſixpence, or leſs than that, and others of more than two feet in diameter: they are all made up of ſeveral circles, like thoſe of a *ſnake* when rolled up, the tail lying in the center, and the larger end, where was the mouth of the fiſh, at the other. Some of them are rounded, others greatly compreſſed, or flatted, and they are at times found lodged in almoſt all the different ſtrata of earth or ſtone.

Some of them repreſent the nave of a cart-wheel, and of theſe ſome are plain, and others ſtudded; ſome alſo are ſmooth, or wholly free from ridges, and others have ridges more or leſs broad; and among theſe, the ridges in ſome only reach acroſs the ſides, without going to the back, and others paſs the back, and form continued lines, going quite round the ſeveral volutæ of the ſhell; and ſome are plain, others ſtudded at their ends; ſome ſpecies have ſimple, and others bifurcated ſtriæ, and ſome are ſtudded and umbilicated; ſome alſo, both of theſe and of the nautili, have a ſort of foliaceous work about their ſutures, which gives a great beauty to the whole. The back of theſe ſhells alſo greatly differs in the different kinds; many of them have a ridge running all the way along the back, which in ſome is plain, and in others is denticulated, or ſerrated; and of theſe ſome have a furrow on each ſide of the ridge, which others want, and ſome have elegant rows of ſtuds running on each ſide this furrow; and finally, ſome have only a ſingle furrow running all the way along their backs. They all conſiſt of ſeveral volutæ, which are different in number in the different ſpecies; and their ſtriæ are alſo extremely various, ſome very deep, and the ridges very high between them, others very ſlight, ſome ſtrait, others irregularly crooked, others undulated, and ſome terminating in dots, tubercles, or cavities, toward the back, and others having tubercles in two or three places.

They are all compoſed of a great number of chambers, or cells, in the manner of the *nautilus Græcorum*, each having a communication with the others, by means of a pipe or ſiphunculus. There is a ſmall white ſhell-fiſh of Barhadoes, which ſeems truly a recent animal of this genus; and in the Eaſt-Indies there is another alſo, ſmall and greyiſh; but the large, and beautifully marked ones, are found only foſſile.

They are compoſed of various foſſile bodies, often of quarry-ſtone, ſometimes of the matter of the common pyrites, and of a great variety of other ſubſtances; and though they appear uſually mere ſtones, yet in ſome the pearly part of the original ſhell is preſerved in all its beauty. Sometimes alſo, while the outer ſubſtance is of the matter of the pyrites, or other coarſe ſtony, or mineral matter, the inner cavity is filled with a pure white ſpar of the common plated texture. This gives a great beauty to the ſpecimen. *Hill's* Hiſt. of Foſſ. p. 649, 650.

The cornua ammonis, or *ſnake-ſtones*, are found in many parts of England, particularly in Yorkſhire, where it is very plentiful in the alum rocks of ſeveral ſizes. See Tab. of Foſſils, Claſs 9.

The people of the place have a tradition, that all the country hereabouts was very much annoyed with *ſnakes*, but that by the prayers of St. Hilda, who lived there, they were all ſent down into the earth, and there turned into ſtone. The common people of this part of the kingdom pay an unſhaken credit to this idle ſtory; but they ſhould conſider, that if a miracle at all, it muſt have been a much more extenſive one of their ſaint than they imagine, for theſe foſſils are found not only in Yorkſhire, but in almoſt every part of the known world. Phil. Tranſ. N° 142.

SNAKE-*weed*, in botany. See BISTORT.

SNAPDRAGON, *antirrhinum*, in botany, the name of a genus of plants, the characters of which are theſe. The flower conſiſts of one leaf of a tubular form, perſonated, and having two lips, the upper of which is bifid, and the lower trifid. The piſtil ariſes from the cup, and is fixed, in the manner of a nail, in the hinder part of the flower; and afterwards becomes a ſeed-veſſel, of the ſhape of the head of a hog, divided into two cells, and uſually filled with ſmall ſeeds fixed to a placenta. See Tab. 1. of Botany, Claſs 3.

The ſpecies of *ſnapdragon*, enumerated by Mr. Tournefort, are theſe. 1. The common *ſnapdragon*. 2. The larger long-leaved *ſnapdragon* with purpliſh white flowers. 3. The white-flowered *ſnapdragon* with reddiſh edges. 4. The white-flowered *ſnapdragon* with very red edges. 5. The white-flowered *ſnapdragon* with yellow edges. 6. The yellow-flowered *ſnapdragon*. 7. The broad-leaved *ſnapdragon* with large pale yellow flowers. 8. The great narrow-leaved *ſnapdragon* with bright red flowers. 9. The Portugal *ſnapdragon* with very large and beautiful red flowers. 10. The great long-leaved Italian *ſnapdragon* with large ſnow-white milky flowers. 11. The hairy origanum-leaved Spaniſh *ſnapdragon*. 12. The hairy Spaniſh *ſnapdragon* with red valerian leaves. 13. The talleſt Spaniſh *ſnapdragon* with very narrow leaves. 14. The middle-ſized *antirrhinum* with a large and wide-open white flower. 15. The greater field-*ſnapdragon* with red flowers. 16. The greater field-*ſnapdragon* with white flowers. 17. The great ſtone *ſnapdragon* with very narrow leaves, and a ſmall purple flower.

The plant called by Caſpar Bauhine, and ſome others, the *cut-leaved ſnapdragon*, is properly a ſpecies of *pedicularis*, and the leſſer field-*ſnapdragon*, and the ſtone mother-of-thyme-leaved *ſnapdragon*, are both ſpecies of toad-flax, or *linaria*. *Tourn.* Inſt. p. 168. See the articles PEDICULARIS and LINARIA.

Many of the ſpecies of this plant are very beautiful, and much eſteemed in gardens, and are all eaſily propagated from ſeeds, which muſt be ſown in a dry ſoil, not too rich, in April or May. In July the plants may be planted out into large borders, where they will flower the ſpring following, or they may be ſown early in ſpring, and they will then flower in the next autumn; but then they are not ſo likely to ſtand the winter, and if the autumn prove not kindly, they will hardly produce a perfect thin ſeed. They all grow very well on old walls, where they have happened to ſow themſelves. *Miller's* Gard. Dict.

SNATCH-*block*, in a ſhip, is a great block with a ſhiver in it, having a notch cut through one of its cheeks, for the more ready receiving in of any rope; for by this notch, the middle part of a rope may be reeved into this *block*, without paſſing it in endways. This ready *block* is commonly faſtened with a ſtrap about the main-maſt, cloſe to the upper-deck, and is chiefly uſed for the fall of the winding-tackle, which is reeved into this *block*, and then brought to the capſtan.

SNIEGULKA, in natural hiſtory, a name given by the common people of Poland to a bird of paſſage, that only comes to them in the colder months.

The name ſignifies the ſnow-bird, and Rzaczinſki, in his Hiſtory of Poland, calls it *nivalis avis*. The people preſage, from its coming, the mildneſs or ſeverity of their winter.

SNIGGLING, a method of fiſhing for eels, chiefly uſed in the day-time, when they are found to abſcond themſelves near wears, mills, or flood-gates. It is performed thus: take a ſtrong line and hook, baited with a lob or garden-worm, and obſerving the holes where the eels lie hid, thruſt your bait into them by help of a ſtick, and if there be any, you ſhall

ſhall be ſure to have a bite; and may, if your tackling hold, get the largeſt of eels. Vid. *Cox*, Gentl. Recr. Part 4. p. 39.

SNIPE, in zoology. See the article GALLINAGO *minor*.

Theſe birds are eaſily taken, by means of lime-twigs, in this manner: take fifty or ſixty birchen-twigs, and lime them all very well together; take theſe out into places where there are *ſnipes*, and having found the places which they moſt frequent, which may be ſeen by their dung, ſet the twigs in theſe places, at about a yard diſtance one from another. Other places, are thoſe where the water lies open in hard froſty and ſnowy weather: in theſe places alſo, and where-ever they are ſuſpected to come to feed, let more lime-twigs be placed in the ſame manner. The twigs are not to be placed perpendicularly in the ground, but ſloping, ſome one way, ſome another; the ſportſman is then to retire to a diſtance, and watch the coming of the birds to theſe places. When they fly to them, they naturally take a ſweep round the earth, and by this means they will almoſt always be caught by one or other of the twigs. When a firſt *ſnipe* is taken, the ſportſman is not to run to take it up, for it will feed with the twig under its wings, and this will be a means of bringing down more of them to the place. When three or four are taken, they may be taken up, only leaving one faſt to entice others; and thus the ſport may be continued, as long as there are any birds of this kind about the place. It may be very proper, when the twigs are planted, to go about, and beat all the open and watery places near, that they may be raiſed from thence, and fly to thoſe places where the twigs are placed to receive them.

SNORT, in the manege, called in French *ebrouer*, denotes a certain ſound which a horſe of fire makes by breathing through his noſtrils; as if he had a mind to expel ſomething that was in his noſe, and hindered him to take breath.

This noiſe or ſound is performed by means of a cartilage within the noſtrils, called in French *ſouris*. Horſes of much mettle *ſnort*, when you offer to keep them in. See the article SOURIS.

SNOTTOLF, a name uſed by ſome authors for a ſpecies of the *orbis*, or globe-fiſh, called by Cluſius, and other authors, the *orbis ranæ rictu*, or frog-mouthed globe-fiſh.

It is uſually of about ſixteen inches in length. It is of a brown colour, variegated with white ſpots. Its head is very thick, and its mouth large and wide, and very much reſembling that of a frog. It has one irregular fin on the back, running nearly all the way to the tail, and two rows of tubercles on each ſide, one on the middle part of the body, the other nearer the belly. It is frequent in the German, and in many other ſeas. The name is Dutch. *Geſner*. p. 747. *Bartholin*. Cent. Obſ. 2. Hiſt. 1.

This fiſh is the *cyclopterus* of Artedi, and the *lumpus* of other authors. See the article LUMPUS.

SNOW (*Cycl.*)—*Snow* may be preſerved by ramming it down in a dry place underground, and covering it well with chaff. At Leghorn they uſe barley-chaff for this purpoſe. See Phil. Tranſ. Nº 8. p. 140.

Snow and ice are alſo preſerved with ſtraw or reeds. Mr. Boyle has deſcribed the manner in his experimental hiſtory of cold.

It is uſual in hot countries to mix *ſnow* and ice with their wine. Hence Pliny [b] ſays, *Hi nives, illi glaciem potant, pœnaſque montium in voluptatem gulæ vertunt*.—[[b] Lib. 19. cap. 4. Martial has an epigram on this ſubject, Lib. 14. Epigr. 117.]

SNOW-*drop-tree*, a very beautiful American tree, which bears the cold of our climate in the open air; but it is very difficult to encreaſe, the layers being two years before they take root, nor will they ever take root at all, except the branches are very young, and are ſlit in the joint, as in the laying carnations. When thoroughly rooted, they may be tranſplanted into ſmall quarters of flowering-ſhrubs, where, among thoſe of a middling growth, they add much to the variety. *Miller*'s Gard. Dict.

SNOW-*ſtone*, in natural hiſtory, a name given by ſome to a very beautiful ſtone found in America; of which the Spaniards are very fond, making it into tables, and other ornaments in their houſes. Alonſo Barba, who had ſeen much of it, tells us, that it is found in the province of Atocama, and is uſually found in pieces of four feet long, and four or five inches broad; ſo that it is forced to be joined in the working. Its general thickneſs is about two inches. It has a great variety of colours, which form clouds and variegations of a very beautiful kind. The principal colours are red, yellow, green, black, and white. The white is generally formed into ſpots on the very blackeſt parts of the maſs, and is ſo beautifully diſpoſed, that it repreſents *ſnow* falling in all its whiteneſs upon a jetty ſurface. *Alonſo Barba* of Metals.

SNUFF (*Cycl.*)—The many miſchiefs attending an unnatural practice of taking this powder of tobacco at the noſtrils, have been deſcribed by the writers in general on theſe ſubjects, ſince this pernicious cuſtom has reigned in the world; but one of the moſt remarkable accidents, occaſioned by it, is related in the Acta Eruditorum.

The caſe is this. A fat perſon, greatly addicted to the taking Spaniſh *ſnuff*, after many years continued uſe of it, complained one day of a mighty uneaſineſs which it occaſioned in the middle of his œſophagus, and ſoon after this he began to find his ſwallowing difficult. He applied for relief to a phyſician, and naming nothing of the pain which had preceded this difficulty of ſwallowing, it was treated as a complaint ariſing from ſome glutinous humor in the œſophagus, it is no wonder that the medicines in this intention had no effect. The patient grew worſe, and tired of this doctor, applied to another, who ſuppoſing the complaint aroſe from ſome ſharp humor vellicating the parts, gave medicines in that intention, equally without ſucceſs. After this a common quack tried the moſt violent medicines on him, but without ſucceſs; and finally he applied to the uſe of the excutia ventriculi, an inſtrument made to be thruſt down the œſophagus into the ſtomach, but this he never could get down; and in the uſe of this inſtrument he firſt felt, that there was abſolutely a lump of fleſh, which ſtopped its paſſage farther than the place where the ſeat of his complaint was. The diſtemper after this encreaſed upon him, till he could only ſwallow liquids, and thoſe at laſt by no other means, but the ſucking them through a quill, by which means he could get down milk, water-gruel, and the like, by a little at a time. At length conſulting another phyſician, and telling him of the immoderate quantity of Spaniſh *ſnuff* he had been uſed to take, and that it often happened to him on taking the drieſt *ſnuff* of this kind; that it got into his œſophagus, and occaſioned violent pain, coughing, and ſpitting of blood, he ſoon concluded that a polypus had formed itſelf in the œſophagus, wounded by this ſharp powder, and that there was no relief, but that the death of the patient was quickly approaching. The man, from a very corpulent habit, was ſo extenuated, that he appeared a mere ſceleton; he died ſome little time after of abſolute hunger, the œſophagus being ſo entirely filled up by this unnatural ſwelling, that not the leaſt drop of a liquid could get down.

After death the œſophagus was opened, and a fleſhy excreſcence, or polypus, was diſcovered, of the bigneſs of the cavity of the part, and taking its origin about the middle, from the back part of the œſophagus, it reached down to the pylorus. This was of a whitiſh colour, and much reſembled a large worm, and its ſubſtance was fibrous, and very tender. Act. Erudit. Anno 1715. p. 457.

SNUFF, or *Snuffler*, in the manege. See the article SNORT.

SOAGGIO, the name of a fiſh common in the markets of Rome and Venice, and of the turbot-kind.

It is the *rhomboides* of Rondeletius, and the *rhombus non aculeatus ſquammoſus* of Willughby.

We have it alſo on our own ſhores, and the Corniſh people, who frequently catch it, call it the *lug-a-leaf*. It has no rough lines at the roots of its fins. Its eyes are large, and ſet at a conſiderable diſtance, and it is covered with extremely minute ſcales. It is extremely flat and thin, and of an aſh-colour.

It is a very ſingular ſpecies of fiſh, differing, in ſome particulars, from both thoſe genera to which it ſeems allied. It differs from the plaiſe-kind, in that it has the eyes, fins, &c. of the turbot, or rhombus; and from that fiſh, in that it is ſcaly, as the plaiſe, and the other fiſh of that genus. *Willughby*, Hiſt. Piſc. p. 95. *Rondel*. de Piſc. p. 358.

SOAL, in ichthyology, the Engliſh name of the fiſh, called by the generality of authors the *bugloſſus*, by ſome *ſolea*.

It is, according to the new ſyſtem of Artedi, a ſpecies of the pleuronectes, and is of that kind which have the eyes placed on the left ſide. Some authors call it the *linguacula*. See BUGLOSSUS and PLEURONECTES.

SOAP (*Cycl.*)—The making of *ſoap* depending only on the mixing the ſalt of pot-aſh with oil or fat, though this is at preſent procured by a tedious operation, and long boiling, it ſeems very practicable to ſhorten, and make the proceſs much eaſier, and leſs expenſive, by ſubſtituting motion in the place of fire. This motion might be eaſily given by an engine to any quantities of the ingredients at a time; and we find it practicable to make *ſoap* by this means, only by mixing in a large vial half a pint of *ſoap*-lees, and an ounce, or more, of oil-olive; for by ſhaking theſe together for a quarter of an hour, an abſolute *ſoap* is procured in a cake at the top of the liquor, which hardens on being expoſed to the air. *Shaw*'s Lectures, p. 160.

The uſe of *ſoap* has, of late, been much extolled in medicine; but then thoſe, who magnify it moſt, except againſt the uſe of it in ſuch caſes where obſtructions are attended with a putrefactive alkali, or where an inflammatory diſpoſition appears. It is acknowledged to be very dangerous in a pthiſis, fever, and ſome other caſes. The biſhop of Cloyne, in his Siris, ſeems to think tar-water an uſeful and ſafe ſubſtitute for it. See the article TAR-*water*.

SOAP-*rock*, or *Soap-earth*, in natural hiſtory. See the article STEATITES.

There is great reaſon to believe, that when we know the proper manner of working, this will, one way or other, make a great ingredient in our porcelain manufactures.

The Chinese have of late discovered a sort of earth, which they call *hoache*. They say that this is hard, smooth, and soft to the touch, like *soap*; these, and its other qualities, seem to prove it to be the same with our *soap-rock*, and this with them makes a sort of porcelain, superior to the common kind in beauty, and in the compactness of its texture, but it is more apt to crack. They use it several ways, sometimes alone, sometimes with the petunse, which is a stone, and sometimes they make a varnish, by dissolving this in water, with which they coat over the common China, covering it finally with the other varnish. All these ways of using it produce very beautiful wares, and it will be extremely worth our while to try them all round, before we give up the use of so valuable a thing. Observ. sur les Coutumes de l'Asie. See the article HOACHE.

SOAR-*hawk*. See the article FALCON.

SOATTO, a Venetian name of a fish, common in the markets there, and of a middle nature between the plaise and turbot. *Willughby*, Hist. Pisc. p. 95. See the article SOAGGIO.

SOAVE, or SOAVEMENTE, in the Italian music, signifies to sing or play in a sweet and agreeable manner.

SOBRE *buena*, a name given by the Spaniards in America to a species of vanilla, which is greatly superior to all the other kinds.

The pods of this are of the same shape with those of the common vanilla, but are nearly twice as large. A bundle, of about fifty of these, usually weighs five ounces, and such a bundle of the *sobre buena* kind often weighs eight. These are full of a blackish balsamic liquor, in which are contained a number of small seeds.

SOCAGERS, in our old writers, such tenants as held by the tenure called *socage*. They were otherwise called *sockmen*. See the article SOCKMEN.

SOCCELLI, among the Romans, were swaths or bands, which covered the leg down to the soccus. *Pitisc.* in voc. See the article SOCCUS, *Cycl.*

SOCII, *allies*, among the Romans. See ALLIANCE, *Cycl.*

SOCK (*Cycl.*)—SOCK and sythe-land. See the article HUSBAND-*land*.

SOCKET (*Cycl.*)—SOCKETS, in a ship, are the holes which the pintles of the murthering pieces go into.

SOCMEN, or SOKEMEN, *socmanni*, such tenants as held their lands and tenements in *socage*; but the tenants in antient demesne seem most properly to be called *socmans*. F. N. B. 14. Briton. c. 66. Terms of Law. *Blount*, *Cowel.*

SOCNA, in our old writers, a privilege, liberty, or franchise. *Blount*. The word is Saxon.

SOCO, in zoology, the name of a Brasilian bird of the heron-kind, but remarkable, beyond all the rest of that genus, for the length of its neck. It is very common in the Brasils. It is smaller than the common heron; its beak is strong, strait, and sharp; its tail short; its head and neck brown, and variegated with black; and its body is of the same colours in different variegations, but its wings have a mixture of whiteness. *Marggrave*'s Hist. Brasil.

SODA, in medicine, the name of a distemper, consisting in an uneasy and troublesome sensation of heat about the orifice of the stomach, which sometimes is owing to external, sometimes to internal causes. It is to be observed, that what we understand by the word *soda* is to be distinguished from the *soda* of the antients, for they expressed by this word a peculiarly sharp and terrible pain in the head.

Signs of a SODA. The persons afflicted with it complain of a disagreeable sensation in the stomach, particularly about the œsophagus, which they do not well know whether to term cold or heat; but it seems rather such a sensation of heat as is produced by the violent colds of winter, than any other, according to the old phrase, that *frigus adurat*, cold burns. With this sensation there is always joined a tensive and pressing weight of the other parts of the stomach, and a light constriction running all the way up the œsophagus, from the stomach to the fauces, attended with a running up of water into the mouth, and a nausea, and frequently a reaching to vomit. It is a distemper that mostly affects persons of plethoric habits, and such as are subject to commotions of the blood.

The internal causes of this disorder are congestions of blood about the stomach and intestines; a bilious foulness in the primæ viæ, and a tremulous motion of the fibres of the stomach. The external causes are the eating great quantities of fat things, and drinking immediately after them, and taking great quantities of the hot aromatics, which exagitate the blood, and bring on a continual irritation. A sudden cooling of the stomach, while the body is very hot, will also occasion this; and the taking of hot medicines, under a notion of strengthening the stomach; and finally, the drinking of feculent liquors, and the eating sower foods.

This is in itself a distemper of no great consequence, but when it is suffered to grow upon the patient, and especially when injudiciously treated, it often is attended with bad symptoms, and sometimes brings on dangerous disorders.

Method of cure. It is often a disease scarce worthy the consideration of a physician, but when it is so, the fixed alkalis, combined with some volatile salt, seem the most proper remedies; such are the tincture of salt of tartar, mixed with spirit of hartshorn, or the alkalis alone, as ten or twenty drops of the oil of tartar: but in those particular cases, where it arises from great commotions of the blood, gentle acids are, on the contrary, the proper means of cure, or the compound powders of nitre and cinnabar. When a bilious foulness is in the cure, the nitrous medicines, with the testaceous absorbents, as crabs eyes, oister-shells, and the like, are the proper remedies; and in all cases, the frequently taking draughts of warm liquors, as of tea, and the like, is extremely proper: and people, who are very much troubled with returns of this complaint, and are of a plethoric habit, are to be advised to bleed and purge every spring and autumn.

The common opinion being, that this complaint is merely owing to an acid humor, has given rise to the use of chalk in it as an universal remedy; and people, who are afflicted with it, usually swallow chalk alone, and that in large quantities, for their cure. But this is by no means a safe, or advisable method: for the chalk meeting with an acid, becomes a violent astringent on mixing with it, and powerfully contracts the tender fibrillæ of the stomach. Whence it often happens, that instead of a cure, the consequences are more painful cardialgias, with obstructions of the viscera, anorexies, and often in women suppressions of the menses. Some give the powder of bricks instead of chalk: but this is more dangerous than the chalk, as it is in itself more astringent. In people, who are afflicted with this complaint from eating fat things, a draught of brandy often proves an immediate cure. *Junker*'s Consp. Med. p. 589.

SODA *subethica*, a term used to express a heavy and dull pain in the head.

SODDING *of brick*. See the article BRICK.

SODE-*shoats*, in botany, a name given by some to the tree, whose inspissated juice is the gum tachamahacca of the shops. Par. Bat. Prodr. p. 379.

SODOMY (*Cycl.*)—There is no Statute in Scotland against *sodomy*; the libel of this crime is therefore founded on the divine law, and practice makes its punishment to be burning alive.

SOFFIETTA, the bellows-fish, a name by which some have called the scolopax, a small sea-fish, common in the markets of Rome and Venice. *Willughby*, Hist. Pisc. p. 161. See the article SCOLOPAX.

SOGETTO, *subject*, in the Italian music, is used for a song or melody, on which some counterpoint is to be made: this may be done variously; thus, 1. *contrapunto sopra il sogetto*, a counterpoint above the subject, is that of which the subject is the bass. 2. *Contrapunto sotto il sogetto*, when the given subject is the higher part. If the subject, in either case, does not change its notes, it is called *sogetto invariato*. But if the notes be changed, either in figure or position, it is called *sogetto variato*. 3. *Sogetto* is also used for the words to which a song is to be made. 4. *Sogetto* is likewise applied to a series of notes, from which a fugue is formed. See the article FUGUE.

SOIL (*Cycl.*)—The land of England, as considered by the farmer, is reduced into nine sorts of *soils*; the sandy, the gravelly, the chalky, the stony, the rocky, the hazely, the black earth, the marsh, and the clay land. Of this last kind there are four varieties, distinguished by their colours; the black, the blue, the yellow, and the red.

In many places these *soils* are mixed and blended together, and where it is so, it is much better than where they are separate or single; especially where the mixtures happen to be of a right kind, as those of the hot and the dry *soils* blended with the cold and the moist. Nature does this often, and art may imitate it. All sands are hot, and all clays are cold, and therefore the laying clay upon sandy lands, or sand upon clayey lands, is the best of all manure: this alters and changes for the better the very nature of the land itself, whereas dung only improves it for a time, and after that leaves it as bad as it was before. Mixt soils, that tend to the clayey-kind, are the best of all others for corn. It is not only the natural *soil* we are to consider, but the depth of it, and what *soil* is underneath; for the richest *soil*, if it be only eight or ten inches deep, and lies upon a cold clay, or upon stone, will not be so fruitful to the farmer as the leaner *soils* that lie upon better under-strata. Gravel or sand are the best under-strata, of all others, to make the land above prolific. *Mortimer*'s Husbandry, p. 64.

Cold and wet clays are much more fruitful in the southern parts of England, than in the north. The climates, therefore, are to be considered, and the quantities or proportions of the different kinds in the mixed soils. The natural produce of the land, as to weeds or grass, is also to be greatly regarded by the person who intends to improve upon it. What is the effect of plowing is next to be enquired into, and experiment must shew what kind of corn agrees best with it.

 All

All land that moulders into duſt with froſt, with all ſorts of warm lands, black mould, yellow clays, if not too ſpewy when wet, and all that turn black after rain, are in general good lands for corn. Land that produces large trees, as alſo ſuch as produces black thorn, weeds, thiſtles, rank graſs, and the like, and that lies in bottoms open to the eaſt or ſouth, being well ſheltered from other winds, may be always eſteemed to bid fair for good land. Thyme, ſtrawberries, betony, and wild ſage, direct to the places where woods will thrive beſt; and camomile is always an indication of a land being diſpoſed to bear corn in large crops.

All land that binds after froſt and rain, all that turns white, and is full of worms, or is very moiſt and cold, or that is too hot and dry, and that lies open to the north on the ſides of hills, expoſed to cold winds and froſts in winter, and to the ſun's ſcorching heat in ſummer; and all that bears naturally holly, box, ivy, juniper, fern or brakes, furzes, broom, and heath; and lands that bear moſſes, ruſhes, yarrow, and wild tanzy, with flags, and other ſuch weeds, which betoken a cold and damp ground, are leſs fit for corn, though other things may ſucceed on it. Where plants appear blaſted, ſhrubby, and curled, theſe are diſtempers in them occaſioned by ſudden changes of wet and cold, and a dry heat. All theſe lands are, by their natural produce, to be judged leſs fruitful than the others. Blackiſh, dun, or yellow ſand, and very hot ſtony gravel, are generally eſteemed very unfruitful. Chalky lands are naturally cold, and therefore they require warm compoſts; and this is the reaſon why chalk itſelf is ſo good a manure for hot and dry lands. Sandy land, well manured with marl, will bear turneps, or white or blue peaſe, to great advantage. *Mortimer's* Huſbandry, p. 68.

The very greateſt article, in the culture of plants, trees, &c. is the *ſoil*; and in many caſes it is not ſufficient to have found a *ſoil*, which once tried proves convenient, to ſuppoſe that it will always continue ſo. In track of time the *ſoil*, which was once proper for the nouriſhment of ſome peculiar vegetable, loſes its virtue; and this ſooner in ſome lands, and later in others. All who are converſant in huſbandry, are well acquainted with this. If a good piece of ground be choſen for the ſowing of wheat, and it produces very well the firſt year, it will not for ever continue to do ſo; the ſecond year's crop will be perhaps good, and the third and fourth tolerable: all this while the land is in heart, as the farmers expreſs it, but after this it becomes improper, and very little wheat will be raiſed if ſown upon it; yet when it refuſes to produce wheat, it will, without any alteration, produce barley in ſufficient plenty for ſome years; when it will yield no more good crops of barley, it may be ſtill ſowed with oats, and will produce that grain as well as freſh land; and when it has been worn out with all theſe, it will produce peaſe. After this it is made quite barren, and can be of no farther uſe to the farmer, the vegetative quality of it being worn off by theſe ſucceſſive crops, each ſort of grain taking off that part which is more peculiarly fitted for its own nouriſhment; the wheat firſt, and the reſt in their order. While one of theſe plants is taking up what belongs to its particular nature, the reſt all remain quiet and undiſturbed; and theſe are afterwards carried away by ſucceſſive changes of plants, which require them; and at length, by the whole, all the vegetable matter is carried away, and the lands ſo drained of it, that there muſt be a ſupply of ſomething in its room, before any thing more of any kind can be raiſed from it. Philoſ. Tranſact. Nº 253. p. 217.

The ſupply of freſh vegetable matter, in the place of that which was drained away by the ſucceſſive growths of plants, is done by ſeveral ways, but by none ſo well, as by letting it lie fallow for ſome time; in this caſe the rain falling upon it, the vegetable earth, which this water contains, is depoſited in ſufficient quantity, and this is alone ſufficient to give nutriment to new crops; and it is proved by this, that the rain water, as well as other water, does contain ſuch earth as is neceſſary to vegetation. The other means of giving a ſupply to the exhauſted earth are the manures laid on it by the farmer, and theſe are, all of them, ſome animal or vegetable remains, and their uſe is to drain into the earth thoſe particles from themſelves, which may be again received into the bodies of new productions of the ſame kinds. Blood, urine, the excrements of animals, with their ſeveral parts, as horns, hoofs, hair, feathers, calcined ſhells, and vegetable bodies in an altered ſtate, ſuch as lees of wine and beer, aſhes of burnt vegetables, leaves, ſtraw, roots, ſtubble, and the like, when in a decaying ſtate, turned under the earth again by plowing, there become diſunited into their component parts, and theſe again are carried up into other new plants.

If we take off our thoughts from the fields, and look among the gardens, we there meet with farther confirmations of the ſame thing: the trees, ſhrubs, and herbs cultivated in theſe, after they have continued in one ſtation, till they have derived thence the greater part of the matter fitted for their encreaſe and nouriſhment, will either decay, or degenerate, unleſs they have a new ſupply of manure added to the earth about their roots, or are themſelves tranſlated into other earth, not ſo drained of that particular matter out of which they are to be fed.

The older trees have ſome more ſupplies of fit matter than the younger, by means of the length of their roots, which, when they have drained one ſpot of ground, uſually are carried much farther into another, and reach a very great way; but at laſt they can reach no farther, and all fails, unleſs ſuch a ſupply of manure, or the being removed into freſh earth, ſupply that nouriſhment they can no longer have where they ſtand. The gardiners, when they tranſplant trees, cut off theſe long roots; but though they only do this to prevent the trouble of opening a larger hole than neceſſary for their reception, yet there is in nature this good reaſon for it, that they have, when brought to a freſh *ſoil*, no occaſion for thoſe long roots to draw nouriſhment from afar off, when there is enough of it every where about them. What is to be learned from the whole of this, is, that the modern ſyſtem is erroneous, which ſays that water is the only thing that gives nouriſhment and encreaſe to plants; ſince, if this was the caſe, there could be no need of manures, nor any need of altering the crop, in order to its ſucceeding, or of tranſplanting trees to make them thrive. It is plain that ſome ſort of terreſtrial matter, taken from among the *ſoil*, is what gives encreaſe and bulk to plants; for were it only water, the rain falling in all places alike, all would alike be at all times ſuited to produce all plants; and if the earth, according to Lord Bacon's ſyſtem, ſerved to no other purpoſe to plants and trees, but to keep their roots firm, and to defend them from over-heat, and over-cold, one earth would do as well for theſe uſes as another, and the ſame earth would do as well for the ſame plant as a different earth. Philoſoph. Tranſact. Nº 253. p. 219.

Mr. Tull thinks, that the only difference of *ſoil*, except the richneſs, is the different degree of heat and moiſture it has; the earth is equally proper, of whatever kind it be, and if theſe additions be properly adjuſted, any *ſoil* will nouriſh any plant. Let a bed of thyme and a bunch of ruſhes be removed into each other's place, without any farther care, and both will die: but let them change their ſoil, by removing the earth wherein the thyme grew, from the dry hill down into the watery bottom, and plant ruſhes therein; and carry the moiſt earth, in which the ruſhes grew, out of its wet place, up the hill, and ſet the thyme in it, it will be found, that the ſame quantity of unchanged earth will ſerve for either: the ruſhes will grow in the earth of the hill when carried into the bogg, and the thyme will grow in the earth of the bottom where the ruſhes before grew, as ſoon as it is carried up the hill. So that while the earth is the ſame, it is only the accidental addition of more or leſs water that makes it fit for the growing of thyme, or the growing of ruſhes.

Earth is the true food of all plants, it is that alone which gives them their encreaſe, and any earth will do for any plant, with the addition of the other acceſſories in due proportion; that is, an acceſſory to vegetation, as water is, but then it does no more than that to give the matter of encreaſe to the plant. The earth of England, when a proper degree of heat is given it in a ſtove, will nouriſh the plants of the Indies; and, on the other hand, the earth of the Indies, when expoſed to the natural cold of the Engliſh climate, will nouriſh Engliſh plants. There is no need, in conſidering the nature of a *ſoil* for plants, to have recourſe to tranſmutation; for whether air or water, or both of them, be, or be not transformed into earth, the thing is the ſame in regard to the plant, if it be earth, when it is taken up by its roots: and it is very certain, from experiments, that neither air alone, nor water alone, as ſuch, can nouriſh plants. Theſe kind of metamorphoſes may properly enough be conſidered in diſſertations purely concerning matter, and to diſcover what the component particles of earth are; but they are not at all neceſſary to be known, in order to the maintaining of plants. *Tull's* Horſehoeing Huſbandry, p. 14.

Brickiſh SOIL, a term uſed by our farmers to expreſs a kind of hazely earth, or land, with a reddiſh caſt. It is frequent in Eſſex, and ſome other counties, and approaches to the nature of a loam. It has no ſtones in it, and does not bind after wet as clay does, but lets all the water in that comes, and has no ſtones in it; whereas all clays hold the water till the ſun exhales, and after rain with a froſt moulder into duſt.

Theſe loams are an excellent mixture for other earths, being a happy medium between two extremes, uniting what is too looſe, cooling what is too hot, and entertaining a moderate ſhare of moiſture.

The beſt produce of the brick earth is rye; if well dunged it will bear white oats, turneps, barley, wheat, buckwheat, and peaſe. The natural produce, in weeds, is broom, fern, quick-graſs, and the like. If it be well dunged, it will produce large crops of clover, but it ſoon wears out of it, and ſhould therefore be ſowed mixed with rye-graſs. The beſt manure for theſe lands is chalk, mixed with coal-aſhes: marl

marl makes a great improvement in them, and there is a ftiff yellow kind of clay, that moulders with the froft, that anfwers the fame purpofe. Whatever amendment is beftowed upon this fort of land by dung, and other enriching things, that do not abfolutely alter the nature of the earth, lafts but a little while. Thefe lands bind very much after rain, and turn whiter; no froft will diffolve the clod, and if they are newly plowed up, and never fo much rain comes on them, people may walk or ride over them almoft as firm as over gravel. If they are not frequently plowed, they are very fubject to worms, which deftroy the winter corn. They yield but poor crops in wet years; the weeds are generally very rank, and the wheat runs all into ftraw. Plowing is a great improvement of them, they always grow well the year after it. Thefe lands are to be ordered for corn in the fame manner with the clay land, only as they are rank, and carry the crop much into ftraw, it is beft to dung them on the etch crop, and to fow them with barley, and never to dung the fallows. Where the farmer has not a mind to plow them, but keep them for grafs, they fhould be mowed one year, and then kept fhort fed with fheep, which will in time fweeten them very much. The red fandy lands in Northamptonfhire are of this kind; they will not hold manure, fo they plow but once for the year's crop, which is juft before the fowing-time, and manure juft before they plow it; for if they plow it oftener, and manure it fooner, they find a great quantity of the beft mould wafhed away below the furface, and out of the reach of the roots of the corn.

In Oxfordfhire they have a fort of red land, which they begin fallowing as foon in the year as they can, before the fun is too high: if it is moderately moift, when fallowed, they efteem it the better, but it fhould not be too wet. They feldom give it a fecond ftirring, and they reckon that if it is too fine and light, it runs to weeds. *Mortimer's* Hufbandry, p. 73.

Soil, in fome parts of England, is ufed as the name for the *phoca*, or fea-calf. See Phoca.

This creature, in Cornwall, they frequently find fleeping on the fhore, and kill him; fometimes by fhooting, fometimes by ftriking over the head with long poles. He defends himfelf, when on fhore, by throwing ftones backward with great violence. *Ray's* Englifh Words, p. 107.

SOJOURNERS, among the Athenians, were permitted to dwell in the city, and follow their own bufinefs, without difturbance, provided they obferved all the laws and cuftoms of the country; but were allowed no fhare in the government. However, they were not allowed to act any thing, or manage any bufinefs in their own names, but were obliged to choofe out of the citizens one, to whofe care and protection they would commit themfelves, whofe duty it was to defend them from all violence and oppreffion. He was called *proftates*. *Potter*, Archæol. Græc. l. 1. c. 10. Tom. I. p. 55. See the article Prostates.

SOKE (*Cycl.*)—Soke-*reeve*, in our old writers, the lord's rent-gatherer in the *foke*, or *foken*. *Fleta*, *Blount*.

SOKHIO, in the materia medica, a name ufed by fome authors for a peculiar fpecies, if it may be fo called, of the lignum aloes.

It is of a greyifh colour, and feems to have been the blea, or outer part of the wood next the bark. *Camell.* Syll. p. 87.

SOLÆUS, in anatomy, a large flefhy flat mufcle, nearly of an oval figure, and thicker in the middle than at the edges. It has its name, from its fuppofed likenefs to a fole. It is fituated on the backfide of the leg, lower down than the gaftrocnemii, by which it is covered, and with which it forms the calf of the leg. It is fixed below, partly to the tibia, and partly to the fibula: it is fixed to above one third of the upper part of the backfide of the fibula, and a little to the articular ligament of the head of this bone. It is likewife fixed to the backfide of the tibia from the oblique line, or impreffion, which terminates the infertion of the poplitæus, down to the middle of the internal angle of the bone; afterwards leaving thefe two bones, it ends in a broad ftrong tendon, which, together with that of the gaftrocnemii, forms what is called the *tendo Achillis*. This ftrong tendon contracts a little in its paffage to the os calcis, and then expanding a little, it is inferted obliquely in the hackfide of that bone all the way to the tuberofity. The flefhy body of the *folæus* feems to confift of, at leaft, two planes of flefhy fibres, that on the backfide of the mufcle being the moft fimple, and the other, or that next the bone, penniform. This mufcle, with the two gaftrocnemii, form what anatomifts call a *true triceps*. *Winflow's* Anatomy, p. 219.

SOLAND, or Solen-*goofe*, in zoology. See the article Goose.

SOLANUM, *night-fhade*, in botany, the name of a genus of plants, the characters of which are thefe. The flower confifts of one leaf, and is of a rotated form, and divided into feveral fegments. The piftil arifes from the cup, and is fixed in the manner of a nail to the middle part of the flower, and finally changes into a roundifh or oval berry, or foft fucculent fruit, which contains many feeds, ufually of a flatted form. *Tourn.* Inft. p. 148.

The fpecies of *folanum*, enumerated by Mr. Tournefort, are thefe, 1. The common *night-fhade* with black berries. 2. The common *night-fhade* with red berries. 3. The common *night-fhade* with yellow berries. 4. The common *night-fhade* with greenifh yellow berries. 5. The berry-bearing African *night-fhade* with frequent and deeply indented leaves. 6. The great Surinam *night-fhade*, refembling the common *night-fhade* in leaves, &c. 7. The perennial Portugal *night-fhade* with large indented leaves, and red fruit. 8. The common climbing *night-fhade*, or bitter-fweet. 9. The white-flowered climbing *night-fhade*. 10. The double-flowered climbing *night-fhade*. 11. The climbing *night-fhade* with variegated leaves. 12. The fea-*night-fhade*, or dulcamara. 13. The common berry-bearing fhrubby *night-fhade*, called *ftrychno dendron*, and *pfeudo capficum*. 14. The tuberofe efculent *night-fhade*, or potatoes. 15. The white-flowered *potatoes*. 16. The prickly African large-fruited fhrubby *night-fhade* with deeply indented leaves, and flowers like thofe of borrage. 17. Black annual Virginian thorny *night-fhade*, fpreading very far, and bearing white flowers. 18. The thorny American *night-fhade* with fire-coloured fpines. 19. The red-fruited Indian fhrubby *night-fhade*. 20. The borrage-flowered Indian thorny *night-fhade*. 21. The thorny and deeply woolly *night-fhade*. 22. The lefs thorny woolly *night-fhade* of China with fmall flowers, difpofed in a fort of umbels. 23. The Indian *night-fhade* with indented leaves, and purplifh black prickles. 24. The fmooth American *night-fhade* with yellow nerves to the leaves, and yellow thorns, and with large fruit. 25. The thorny American *night-fhade* with leaves like thofe of the mad-apple, or melongena, and large fruit. 26. The fhrubby acanthus-leaved American *night-fhade*. 27. The prickly peach-leaved American *night-fhade*. 28. The prickly bay-leaved fhrub American *night-fhade*. 29. The woolly-leaved climbing American *night-fhade*. 30. The woolly mullein-leaved American *night-fhade* with fmall yellow fruit. 31. The American fhrubby *night-fhade* with the common *night-fhade* leaves, and fmall red fruit. 32. The tree American *night-fhade* with undulated almond-like leaves, and large white flowers and red fruit. 33. The fingle feeded fhrubby American *night-fhade* with polycanthus leaves. 34. The prickly climbing American *night-fhade* with henbane leaves, and flowers, purple without, and white within. *Tourn.* Inft. p. 149.

Solanum *pomiferum*, *apple-bearing night-fhade*, a name given by writers to the *night-fhades*, and plants of feveral genera, allied to thofe, and bearing large fruits. See the articles Melongena and Lycopersicon.

Solanum *fomniferum*, *fleepy night-fhade*, a name given by Cafpar Bauhine, and fome others, to a fpecies of winter-cherry, the whorled alkekengi with fmall fruit. See the article Alkekengi.

SOLAR (*Cycl.*)—Solar *comet*. See the article Discus.

SOLATRUM, in botany, a name given by many authors to the common night-fhade. *Ger.* Emac. Ind. 2.

SOLDANELLA, *fea bind-weed*, in botany, the name of a genus of plants, the characters of which are thefe. The flower confifts of one leaf, formed into the fhape of a bell, and jagged or fimbriated at the edges in moft fpecies; from the cup of this flower rifes a piftil, which perforates the bottom of the flower, and is fixed like a nail to its hinder part; this afterwards ripens into a cylindric fruit, which opens at the top, and is filled with feeds fixed to a placenta.

There are only three known fpecies of this plant. 1. The common round-leaved kind. 2. The white-flowered round-leaved Alpine kind. 3. The Alpine kind with lefs rounded leaves. *Tourn.* Inft. p. 82.

In the Linnæan fyftem of botany, the characters of this genus are thefe. The cup is an erect perianthum, divided into five pointed fegments, and remaining when the flower is fallen. The flower confifts of one petal, in the fhape of a bell, widening by degrees to the mouth, where it is notched and jagged. The ftamina are five tapering filaments. The antheræ are fimple. The germen of the piftil is roundifh. The ftyle is flender, of the length of the flower, and remains when that is fallen. The ftigma is obtufe. The fruit is an oblong cylindric capfule, obliquely ftriated, containing only one cell, opening, and having ten indentings on the top. The feeds are very numerous, extremely fmall, and pointed, and their receptacle is columnar in figure, and loofe. *Linnæi* Gen. Plant. p. 64.

Soldanella is alfo a name very improperly given by many authors to fome of the proper and genuine fpecies of bind-weeds; as the purging fea-bind-weed with roundifh leaves and purplifh flowers, the great Italian fea-bind-weeds with finuated leaves, and the common round-leaved fea kind. See the article Convolvulus.

SOLDER (*Cycl.*)—*Silver*-Solder. Though fpelter *folder* be much cheaper than *filver-folder*, yet workmen in many cafes prefer the latter. And Mr. Boyle [u] informs us, that he has found it to run with fo moderate a heat, as not much to endanger

endanger the melting of the delicate parts of the work to be *foldered*; and if well made, this *filver-folder* will lie even upon the ordinary kind itfelf; and to fill up thofe little cavities, that may chance to be left in the firft operation, which is not eafily done without a *folder* more eafily fufible than the firft made ufe of.—[b Works Abridged, Vol. I. p. 135.]

SOLDIDO, a name given to the *tamoato*. See TAMOATO.

SOLDIER (*Cycl.*)—The profits attending the profeffion of a *foldier*, among the Romans, were very confiderable. 1. Booty and plunder, with which they frequently returned home loaded, efpecially after taking any cities or towns; for thefe were generally given up to be plundered. 2. The fubdued countries, which were often divided among the *foldiers*. 3. Their pay. 4. Cloaths. 5. Provifions. 6. Farms and houfes in provinces were alfo given them. 7. Many privileges and immunities, as that none could touch his goods in his abfence in the camp. 8. Legacies, which the emperors left to be diftributed among them. 9. Donatives. 10. Promotions to military honours lay open to every brave man, though of the meaneft birth. *Pitifc.* in voc.

SOLEÆ, among the Romans, were a kind of fandals or flippers, which covered only the fole of the feet, and were bound on with thongs of leather; inftead of which the women, and effeminate perfons of the other fex, tied them on with purple-coloured ribbands, or fuch as were varioufly adorned with gold and filver. *Pitifc.* in voc.

SOLEN, the *razor-fifh*, in natural hiftory, the name of a genus of fhell-fifh, the characters of which are thefe. They have bivalve fhells with an oblong body, and are open at both ends. They are ufually ftrait, but in fome fpecies crooked. It had its name *folen* from the Greek, in which language that word expreffes a pipe or tube; this fifh, when the fhells are clofed, very aptly refembling a tube. The Latin writers have called it *unguis*, from its refemblance in colour and confiftence to the human nail. The common people, in many parts of France, call it *coutelier*, and in Italy it is commonly called *cannolichio*.

Rondeletius obferves that there are, among the *folens* of the fame fpecies, males and females, which are eafily diftinguifhable from one another; and that the females are larger, have no variegations on the fhells, and are much better tafted than the males. Rumphius has defcribed a very remarkable fpecies of *folen*, which always remains buried in fand, and which is not properly a bivalve, confifting only of one piece, though of the fhape of the *folen*; he calls this *folen arenarius*. Lifter has called the crooked fpecies *folenes curvi*, and fome call them the *fcymitar folens*.

We have feveral fpecies of the ftrait *folens*, though but few of the crooked ones. Of the firft kind are, 1. the common white *folen*. 2. The red American *folen*. 3. The variegated *folen*. 4. The zoned *folen*, called the *onyx-fhell*. 5. The brown *folen*. 6. The large dufky *folen*. 7. The *unguis*, properly fo called. This exactly, in texture and appearance, refembles the human nail. 8. The finger *folen*, called *dactylus* by the antients. 9. The flute or pipe *folen*. 10. The reed *folen*. 11. The long brown *folen* with a thick black mufcle at the cardo. See Tab. of Shells, N° 23.

Of the crooked *folens* the following two are the only known fpecies. 1. The fcymitar *folen*. 2. The *folen arenarius*, always found in fand.

The fhell of this fifh is compofed of two pieces, which are the two halves of a hollow cylinder with an elliptic bafe, divided in a longitudinal direction. Thefe two pieces are faftened together near one end by a ligament, like that which joins the fhells of the mufcle or the oifter. From the place where this ligament is fixed, quite to the other end of the fhell, there is a membrane faftened to each edge of the fhells, and this encreafes in breadth in proportion to its diftance from the place of its origin; fo that viewed externally, it forms a fort of ifofceles triangle, the bafe of which has about two lines in breadth. The colour and confiftence of this membrane give it very much the appearance of a piece of parchment; it has a confiderable fpring in it, and ferves on occafion to open, or draw together the two fides of the fhell.

There is another membrane, of the fame kind with this, faftened to the other fide of the fifh, there adhering to each fhell, but this is of an equal breadth all the way down: this ferves alfo to fhut or open the edges of the fhell. When the *folen* fhuts its fhell, it folds itfelf into feveral longitudinal wrinkles, which open again when the fides of the fhells feparate.

Hence it is to be obferved, that though this fhell has a power of opening and fhutting, yet the body of the fifh is always fecured, and is no more expofed to fight at one time than at another, and there is no part where the fifh can be feen but at the ends.

This fifh lives in the fand on the fea-fhore, where it buries itfelf often a foot and a half, or two feet deep; the length of the fhell is, at this time, nearly in a vertical pofition, and the fifh has a power of raifing itfelf at pleafure up to the furface, and finking down again, while the fhell remains all the time buried in its place. Almoft all other animals have an horizontal motion, and the fhell-fifh of the fea crawl along upon its bottom under water, as the common land animals do on dry ground; but this creature's progreffive motion is only vertical, and that confined to a very fmall compafs, all that it is able to do for itfelf, being only to raife itfelf higher or lower, and fink deeper or rife higher in the fand, within the narrow compafs of about two feet at the utmoft, as the going beyond that muft occafion its deftruction. Where thefe fhell-fifh are buried in the fand, there is a hole reaching from every one of them to the furface, by means of which they have a free communication with the water: thefe holes generally are placed in great numbers near one another, and are eafily diftinguifhed at a time when the tide has left the fhore uncovered. They are not round, but oblong, and fomewhat refemble the key-hole of a lock, but that they have a roundnefs at each end, whereas that ufually is rounded only at one. When the winds are violent, they blow the fand about, and ftop up thefe holes, otherwife, whenever there are any of thefe fifh, they are eafily difcovered. When the fea is down, thefe fifh ufually run deep into the fand, and to bring them up, the common cuftom is to throw a little falt into the holes, on which the fifh raifes itfelf, and in a few minutes appears at the mouth of its hole. When half the fhell is difcovered, the fifherman has nothing more to do than to take hold of it with his fingers and draw it out, but he muft be cautious not to lofe the occafion; for the creature does not continue a moment in that ftate, and if by any means the fifherman has touched it, and let it flip away, it is gone for ever, for it will not be decoyed again out of its hole by falt; fo that there is then no way of getting it but by digging under it, and throwing it up with the fand. This fifh has two pipes, each compofed of four or five rings or portions of a hollow cylinder, of unequal lengths, joined one to another, and the places where they join are marked by a number of fine ftreaks or rays. Now the reafon why the falt makes thefe creatures come up out of their holes, is, that it gives them violent pain, and even corrodes thefe pipes: this is fomewhat ftrange, as the creature is nourifhed by means of falt water; but it is very evident, in that if a little falt be ftrewed upon thefe pipes in a fifh taken out of its habitation, it will corrode the joinings of the rings, and often make one or more joints drop off: the creature, to avoid this mifchief, arifes out of its hole, and throws off the falt, and then retires back again. The ufe of thefe pipes to the animal, is the fame with that of many other pipes of a like kind in other fhell-fifh, they all ferve to take in water; they are only a continuation of the outer membrane of the fifh, and ferve indifferently for the taking in and throwing out the water, one receiving, and the other difcharging it, and either anfwering equally well to their purpofe.

When one of thefe fifh is taken out of its hole, and laid upon the fand, if any thing touches it, it immediately gets in order for its progreffive motion. It throws out a long cylindric part, of half the length of the fhell, and of the fhape of a clapper of a bell; this is fufpended to the middle of the animal by a ligament, but in all other parts it is loofe; this ferves as a leg to the creature: as it lies upon the fand, it extends this about an inch from the end of the fhell, and changes its cylindric figure to a flat one, which terminates in a point, flat and fharp at the edges; with this it opens its paffage into the fand. When the opening is made, it extends this part ftill farther, and buries it deeper, and after this bends it back again in fuch a manner, that its point turns up towards the fhell; thus it gives this part a figure of a hook, and by this hook it draws its whole body and fhell down. In this attempt it brings the edges of the fhells every where clofe together, and inftead of lying flat upon the fand, it now by degrees gets into a vertical pofition, and then there remains nothing to do, but to draw it deeper into the fand. To effect this, it now again extends its leg, which it eafily paffes into the fand in its flatted fhape, and when it has thus pierced to its utmoft length, the creature inflates, and extends it by degrees to the fize of the fhell, and to a round or cylindric figure; the confequence of which is, that there is now a hole made of the fhape of the fhell, and equal to its diameter, into which it can eafily fink: to facilitate this, however, the creature fwells out the extremity of the leg into a fort of button, which holding faft in its place, nothing more is neceffary than to contract the reft of the leg, in order to pull down the fhell after it. This operation is repeated as often as is neceffary, and the creature, at every movement of this kind, getting down half the length of its fhell, or thereabouts, is very foon plunged as deep as its occafions require.

When it has occafion to afcend out of its hole, the fame leg ferves for that purpofe; nothing more being required, than the putting out the end of the leg, fwelling it, and thus thrufting itfelf up to the length of that leg; then retracting it into the fhell again, and thrufting out, and inflating its end for a fecond movement of the fame kind. Thefe motions may be all perceived in the creature when out of the fand, particularly that by which it buries itfelf; for if held up in the fingers, it thrufts out the leg, and performs all the motions as if in the fand, making a fruitlefs attempt to

fave itfelf in its old way. Mem. Acad. Par. 1712. See the article DACTYLUS.

Klein, and fome others, have given the name *folen* to the feveral fpecies of *tubuli marini*.

The word is derived from the Greek, σωλη, tubulus. Of thefe there are feveral genera, diftinguifhed by their proper characters.

1. *Solen lignorum*, the wood tubule. This is a *tubulus marinus*, or fhelly cafe of a fea-worm, of a white colour, not cut, of the thicknefs of a goofe-quill, more or lefs, and very irregularly bent and contorted.

2. *Solen arenarius*, the fand tubule. This is defined to be a *tubulus marinus*, in form of a very long tube, which is thick, jointed, and gradually tapering from one end to the other, and divided into new pipes of the fame kind. *Klein*, de Tub. Mar. p. 12.

3. The *folen anguinus*, or fnake tubule. This is defined to be a *tubulus marinus*, which is varioufly bent and waved, in the manner of a fnake. Of thefe there are feveral fubdivifions; fome are fmooth, and terminate in a beautifully twifted end; others are varioufly and very elegantly folded, and others are of a triangular form, and are triangular tubes terminated at one end with a number of flight obtufe notches or teeth, as they are called by fome; and finally, fome are found with a fiffure running down their whole length, and regularly marking the middle of all their fnail-like volutions. *Klein*, de Tub. p. 3.

4. The *folen vermicularis*, or worm tubule. Thefe are diftinguifhed from the others by being very long, and folded like our large earth-worms. Of thefe alfo there are feveral kinds; fome defcribed by Rondeletius, Johnfon, and other authors, under the name of worms hiding themfelves in tubes, *vermes in tubulis delitefcentes*. Thefe are of a cylindric figure, white, rough on the outfide, but very fmooth within, and are fometimes perfectly ftrait, fometimes crooked and folded. Within thefe fhells the exuviæ of the animal-inhabitant may be often diftinguifhed. *Klein*, de Tub. p. 4.

Others of thefe are of an angular figure, often trigonal, and not unfrequently thefe are found twifted into beautiful fpiral lines.

Others, from their fimilitude to the inteftines of fmall fifh, have been called *vifcera pifcium* by authors. Thefe are ufually fomewhat rough, and lie hid in the mud, under and among the rocks: they are commonly of an earth colour, or dufky brown.

Others are fo tough and foft as to be flexile; thefe refemble an earth-worm, or the gut of fome fmall animal in form, and are of a rough fandy conftruction, and often are found above a foot long.

Others are fmall, lightly ftriated, or cancellated, and ufually of a reddifh colour; and finally, others are very fmall, perfectly white, and often turned like a nautilus: thefe are very common on almoft all marine bodies, being fometimes found adhering to the leaves of the fea-fucufes, often to fhells of various kinds, and very frequently to the claws of lobfters, *&c.*

5. The *folen corallorum*, or coral tubule. This is a very capacious tubule, refembling parts of the thicker and larger inteftines, whether empty or ftuffed; and are at one end affixed to the rocks, particularly to thofe on which the corals are found, and open at the other. Of thefe there are two principal kinds, the one fmooth, the other corrugated or wrinkled. Of the fmooth ones fome refemble a boot in figure, and have been called *ocreati*, and *boot-fhells*; others are low and vaulted, and refemble the hollow of an oven; thefe alfo, for this cafe, have been called *clibaniformes*. *Klein*, de Tub. p. 5.

6. The *folen phalloides*, or tubule refembling in figure the membrum virile. This is a large, white, and fmooth tubule, much refembling in figure the part from which it has its name. It frequently refembles a fort of thick root, and at its lower end there ftands out a fort of fiphunculus, which is perforated. Lifter has defcribed this under the name of *phallus*. *Klein*, de Tub. p. 6.

7. The *folen fragilis*, or brittle tubule. This is diftinguifhed from the reft by its fragility, being compofed, in a manner, only of loofe fand, and always falling to pieces with a flight touch. Of thefe fome are of a finger's length, rough on the outfide, and fmooth within, flender, and ufually found full of water; others have a great deal of fand in their compofition, but are fo contrived, that they are fmooth both within and without, and pellucid. *Klein*, de Tub. p. 7.

SOLE, in the manege, is a nail or fort of horn under a horfe's foot, which is much more tender than the other horn that incompaffes the foot, and by reafon of its hardnefs is properly called the *horn*, or *hoof*. A horfe's fhoe ought to be fo fet upon the hoof, as not to bear upon the *fole*; for otherwife the *fole* would be hurt, and not only make the horfe lame, but corrupt the flefh that feparates it from the coffin-bone.

To take out the *fole*, is to do it without touching the horn of the hoof; for if you take off the horn, you make a *hoof-caft*. We take out the *fole* for feveral infirmities, as may be feen in Mr. Solleyfel's Compleat Horfeman. A horfe that is *unfoled*, may recover in lefs than a month.

High-foled, called in French *pied comblé*, is faid of a horfe whofe *fole* is round underneath; fo that it is higher than the hoof, and oftentimes makes the horfe halt, and hinders the fhoeing of him, unlefs the fhoe be vaulted.

SOLEA, the *foal-fifh*, a well known fifh, and much efteemed at table.

It is diftinguifhed from the fifh of the plaife-kind, in that it is of a longer and narrower fhape. Its upper part is of a blackifh grey, its under, or belly, white. It is covered with fmall fcales, armed at their extremities with a fort of fhort prickles. The fins that furround the body are all inclined from the head toward the tail. The eyes are fmall, and covered with a loofe fkin. The pupils are of a fine bright green. It is a firmer fifh, by much, than the plaife. It is common in the Mediterranean, Englifh, and German feas. *Willughby*, Hift. Pifc. p. 100.

SOLFEGGIAMENTO, in the Italian mufic, compofitions, of which the fyllable *ut*, or *do*, *re*, *mi*, *fa*, &c. are the fubject. See SOLFEGGIARE.

SOLFEGGIARE, SOLFIZARE, or SOLMIZARE, in the Italian mufic, is the ufing the fyllables *do*, *re*, *mi*, *fa*, &c. in learning to fing, otherwife called *folfaing*. See the article SOLFAING, *Cycl.*

From this muficians have made what is called a *folfeggiamento*, which properly intimates no more than the practice abovementioned; but the name is more particularly applied to certain compofitions, be they fugues, or others, of which thefe fyllables are the fubject. Several very fine pieces of this kind are extant. *Broffard.*

SOLFIZARE, in the Italian mufic. See the article SOLFEGGIARE.

SOLID *body in geometry*, that which has three dimenfions, length, breadth, and thicknefs. *Ozan.* Dict. Math. p. 117. *Wolf*, Elem. Geom. fect. 421.

Such are prifms, cubes, fpheres, parallelopipeds, cylinders, cones, pyramids, *&c.* *Wolf*, lib. cit. cap. 2. p. 186. See each under its proper article, PRISM, CUBE, CYLINDER, *&c.* *Cycl.*

For the ratio of geometrical *folids*, all prifms, parallelopipeds, cylinders, pyramids, and cones, are in a compound ratio of their bafes and altitudes: fo that if the bafes be equal, they are in the fimple ratio of the altitudes; or, if the altitudes be equal, of the bafes. And as the bafes of cylinders and cones are circles, and circles are in the duplicate ratio of their diameters, it follows that all cones and cylinders are in a ratio compounded of the direct ratio of their altitudes, and the duplicate one of their diameters. *Wolf*, Elem. Geom. fect. 510, feq. Ejufd. Elem. Anal. fect. 106.

Regular SOLID. See the Cyclopædia.

Irregular SOLID, a *folid* which is not terminated, or contained under equal and fimilar furfaces. *Wolf*, lib. cit. fect. 428. *Ozan.* Dict. Math. p. 120.

The *folidity* of a regular body is eafily found from principles of geometry [c]; for that of irregular bodies, mechanical methods are ufed: one is by putting the body in a hollow parallelopiped, and filling up the remaining fpace with water or fand; then taking out the body, and obferving the heighth to which the water or fand rife alone [d]. This gives us a parallelopiped, equal to the given body, whofe folidity is eafily found.—[[c] *Wolf*, lib. cit. fect. 497. [d] Ibid. fect. 498.]

See the article PARALLELOPIPED.

SOLID *root*, among botanifts, expreffes the whole *root* to be one uniform lump of matter. See the article ROOT.

SOLEIL *de mer*, in zoology, a name given by the French writers, and by Rondeletius, to a peculiar fpecies of ftar-fifh, of a fmall fize, the legs of which refemble very much the tails of lizards, and are very brittle.

Gefner defcribes alfo a fpecies under the name of the fea-moon, *luna marina*, which he fays is remarkably fragile, and which, from what elfe he has faid of it in its defcription, appears alfo to be the fame creature. The great character, however, of the creature's legs refembling, both in colour and figure, the end of the common brown land-newt's tail, is fo expreffive, that it cannot but be always known by it.

Thefe rays are fo extremely friable, that it is fcarce poffible to touch them without their breaking, and they are not befet with points in the manner of the common rays of the creatures of this kind: their upper furface is rounded, and covered with a fort of circular fcales; the under furface is, in the fame manner, covered with fcales, but it is flat: thefe fcales alfo differ in figure, being only fegments of circles, whereas the others are compleat rings; thofe on the underfide are beautifully arranged, in an alternate order, of two and one all the way along the rays.

The other rays of ftar-fifhes being furnifhed with many hundred legs, and thefe wanting them entirely, it follows, that in this fpecies the rays themfelves muft fupply the place of legs, and affift the creature in walking; and thence its manner of walking muft neceffarily be different from that of any other kind. Thefe rays are five in number, and are inferted very near the mouth of the creature, which is always placed in the center of the ftar: the part where this aperture is fituated, and which may be called the body of

the animal, is of a roundifh figure; the diameter of it is about a third part of the length of the rays; its under furface is flat, and its upper convex; and it is covered, both above and below, with fcales, but they are arranged in different manners. At the infertion of each of the rays, there is placed a triangular membrane, terminating in a fharp point; and thefe membranes only appear, when the creature is immerfed in water, and moves itfelf about.

The common habitation of the fea-ftars, on the rough fhores of the fea, is no place for thefe tender creatures, every dafh of a wave againft a ftone, if they were in the way, would break off their limbs; they have the caution, therefore, to fix their refidence only in calm places, and where the fhore is covered entirely with a deep fmooth fand. They are often buried in the fand, and often, when the water has forfaken them, are feen walking flowly on the fhore; and in this cafe they ufe their rays as fo many legs. As they divide the body of the fifh into equal parts, there is no ray before or behind any where, fo that the creature goes with equal eafe to any fide that it likes. The beft motion they are able to make is, however, very flow, and the ground on which they march ought to be very even; for if they attempt to haften their pace, or if they find any thing uneven in their paffage, one or more of their legs ufually breaks; and this is the reafon why this fpecies is feldom found with its rays perfect. They never bury themfelves deep in the fand, but juft get under it, fo as to be covered; and this they do by advancing two of the rays together, and burrowing carefully with them, and then following them with the reft of the rays and the body. Mem. Acad. Par. 1712.

SOLIFUGA, in natural hiftory. See SOLIPUGA.

SOLIPUGA, in natural hiftory, that name given by the Romans to a fmall venomous infect of the fpider-kind, called by the Greeks *heliocentros*, both words fignifying an animal which ftings moft in the country and feafons where the fun is moft hot.

Solinus makes this creature peculiar to Sardinia; but this is contrary to all the accounts given us by the antients. Pliny tells us of its being common in Ethiopia, and that in fome places there the inhabitants had been all killed by the ferpents and *folipugæ*; and Lucan gives the hiftory of it among the poifonous reptiles of Africa.

Almoft all the hot countries produce this venomous little creature. It lies under the fand, to feize other infects as they go by; and if it can meet with any uncovered part of a man, will bite him, and the wound will prove very painful and envenomed. It is faid that the bite is abfolutely mortal, but probably this is not true. Solinus writes the word *folifuga*, and fo do many others, erroneoufly deriving the name from its flying from the fun's rays, and burying itfelf in the fand.

Pliny fays that it was an ant of the fhape of a fmall fpider, but his accounts of this kind are too confufed to be much depended on. Some of the old commentators wander yet farther from the truth, and call it a kind of fly; but the defcriptions of it, by thofe moft to be trufted, make it a fpider, and it feems to be that called by Ariftotle *phalangium defticum*, the deadly fpider. It is plain that even Pliny, in fome part of his works, has underftood the creature to be this phalangium; for where he has tranflated the old Greek writers on the fubject of the phalangium, he has very frequently rendered the word not phalangium, but *folipuga*: fo that it is wonderful he fhould, in other places, treat of the phalangium, without any mention of the *folipuga*, and of the *folipuga*, in a different part, as not at all allied to the phalangium. It appears from this, and a great many like things, that Pliny wrote his book at different times, and tranfcribed his accounts from different authors; fo that he fometimes forgot what he had before written on the fame fubject under a different name.

SOLLECITO, in the Italian mufic, is fometimes ufed to exprefs that a piece is to be played in a mournful manner, fit to enforce grief upon the hearer; at other times, that it ought to be done carefully and with exactnefs. *Broffard*.

SOLMIZARE, in the Italian mufic. See SOLFEGGIARE.

SOLO, in the Italian mufic, is frequently ufed in pieces confifting of feveral parts, to mark thofe that are to perform alone; as *flauto folo*, *violino folo*.

It is alfo ufed for *fonatas* compofed for one violin, one German flute, or other inftrument, and a bafs: thus we fay, *Coralli's folos*, *Geminiani's folos*, &c.

When two, or three parts, play or fing feparately from the grand chorus, they are called a *doi foli*, a *tre foli*, &c.

Solo is fometimes denoted by *S*.

SOLOMON's *feal*, a plant, called by authors *polygonatum*. See the article POLYGONATUM.

SOLSEQUIUM, a word ufed by fome chemical writers as a name for fulphur.

SOLOS, σολος, in antiquity, an inftrument with which the exercife of the quoit was performed, which fome will have to be diftinguifhed from the difcus, becaufe that was of iron, this of ftone: but others, with more reafon, report that the difference confifted in this, *viz.* that the σολος was of a fpherical figure, and the difcus broad. *Potter*, Archæol. Græc. Tom. I. p. 443.

SOLVENTS (*Cycl.*)—Among the feveral liquors, which are called *folvents* of the metals, there are fome which entirely diffolve them, others which diffolve only a part of them. Common water is the moft general of all *folvents*; it diffolves all metals by attrition alone. Mercury does not eafily diffolve iron, but it readily enough diffolves all other metals. Acids in general alfo diffolve them all; but thefe acids being of different natures, fome of them diffolve fome particular metals, and do not touch the reft. The general divifion of the acid *folvents* is into two kinds, thofe of the nature of aqua fortis, and thofe of the nature of aqua regia. The laft are either the fpirit of fea-falt alone, or any of the other acids, with the addition of fea-falt, or its diftilled fpirit; and the firft are fpirit of nitre, and all other mixed menftruums, in which fpirit of nitre makes a part, provided there be no fpirit of fea-falt, or of that falt in fubftance in them. There is alfo a third clafs, befide thefe, of what are called the fimple acids; thefe are fuch acid liquors as contain neither nitre nor fea-falt, nor any preparation of them; and of thefe fome are obtained from the animal, fome from the vegetable, and fome from the mineral kingdom.

All the *folvents* of the aqua regia clafs diffolve gold, without diffolving filver, and all thofe of the aqua fortis clafs diffolve filver, without touching gold: but the other acid fpirits, and the aquæ regales, and aquæ fortes, all equally diffolve the leffer metals, if made of a proper degree of ftrength for each metal. It was long fuppofed, that mercury was only foluble in the aqua fortis clafs, but Mr. Homberg has proved that the aquæ regales will alfo diffolve it; and the fame accurate chemift has alfo advanced another fact, which more than this contradicts the received opinions: this is, that filver is alfo foluble in aqua regia, if proper circumftances are obferved. The occafion of his advancing this, was the following obfervation. He often made his aqua regia, by diftilling together two parts of falt-petre, three parts of vitriol, and five parts of fea-falt; in the diftillation he ufed to feparate the phlegm which rofe firft, and keep it in a vial by itfelf, and the fpirit that followed in another.

One day having fome gold to diffolve, he by miftake took down the vial which contained the phlegm of the aqua regia, inftead of that which contained the ftrong fpirit; he poured on a quantity of this phlegm to the gold, and fet it in a proper heat for two hours, when taking it out, the liquor was found to be tinged yellow, but the gold was not diffolved. Not recollecting the miftake, he fuppofed he had taken aqua fortis inftead of the aqua regia, and taking out the gold he weighed it, and found it had not loft a grain. On this he put in a piece of filver to the liquor, and placing it again in the fame heat, this metal was foon diffolved into a fort of black mud. In this folution there appeared nothing of that ebullition, which always attends the diffolving filver in aqua fortis; and Mr. Homberg, furprifed at this, was for repeating the operation; when pouring the liquor upon fome frefh filver, it did not appear to diffolve it at all: in enquiring into the caufe of this, he found that the liquor he had taken was not aqua fortis, but the phlegm of aqua regia. On this the event feemed much more remarkable than before, and he repeated the procefs feveral times, and always with the fame fuccefs; but trying it a year afterwards, he found the event exactly contrary, the fame liquor then diffolving gold, and not touching filver: after this making fome of the phlegm afrefh, he found it would diffolve filver, and not gold, as in the firft experiment; and this, when it had been kept a year, again changed its nature, and would then diffolve gold, and not filver. So that, from the whole, there appear three neceffary circumftances for the making aqua regia diffolve filver; the firft, that it be very weak; the fecond, that it have before had gold in it; and the third, that it be frefh diftilled.

This phlegm of aqua regia is pellucid, and colourlefs as water, before it has been poured upon the gold; after this it becomes lightly tinged with yellow, and when after this it is powered upon the filver, it becomes as black as ink. The folution of filver, in this menftruum, is very different from that in aqua fortis; in the laft it is made with great ebullition, and the folution, when perfected, is limpid as water; in the other there is no ebullition, and the folution appears rather a difunion of the parts, for the whole becomes black and turbid, and differs much from a clear folution. Mem. Acad. Par. 1706.

SOLUTION (*Cycl.*)—*Chemical* SOLUTION. The great Boerhaave has fummed up the doctrine of *chemical folution*, by its feveral agents, in the following fuccinct manner.

1. *Solution* is performed by water, by diluting, infufing, boiling, diftilling, mixing, fermenting, putrefying, and feparating.

2. With oil, by diluting, infufing, boiling, diftilling, mixing, feparating, but not by fermenting, or by putrefying.

3. With fire, by calcining, roafting, burning, melting, fubliming, mixing, feparating, and by the promoting feveral other operations.

4. With the affiftance of air, by fermenting, putrifying, agitating, exciting, and adding other parts capable of diffolving.
5. With fermented fpirits, by diluting, infufing, boiling, diftilling, mixing, and making oils thinner.
6. With alkaline falts, by calcining, torrefying, burning, melting, mixing, and feparating, according to the various force of a dry fire employed.
7. By volatile alkaline falts, by fubliming in the dry way, and by diluting, diftilling, and digefting in the moift way.
8. With fixed alkali falts, affifted and moved by water and fire, by digefting, boiling, diluting, feparating, and mixing.
9. With fixed acid falts, as thofe of alum, fulphur, and vitriol; either feparately in a liquid form, or in their calxes, by diluting, boiling, diftilling, digefting; or in a dry form, by calcining, roafting, burning, and diftilling.
10. With volatile acid falts, by diluting, digefting, diftilling, and infinuating.
11. With compound falts and foaps, by calcining, fubliming, diftilling, and digefting, either in a dry or a liquid form.
And 12. with metals, by fufion and amalgamation.
This feems an accurate and perfect table of the whole work of *folution*, and will eafily be underftood in every article, on recollecting the feveral chemical proceffes. *Boerh.* Chem. Part. 2. p. 338. See MENSTRUUM, *Cycl.* and *Suppl.*
No phænomenon in nature is more univerfally known, than the *folution* of falts in common water, but the world has not yet attended to all that might be learned from the obfervations on it.
Mr. Lemery, who examined into this point with great affiduity, has obferved, 1. That the firft effect of water upon a falt, is the reducing it into an inexpreffibly fine powder. 2. That it is merely the confequence of this pulverifation carried greatly farther, that every particle of falt which, while in larger moleculæ, fubfided to the bottom of the water, according to the known laws of hydroftatics, becomes capable of being elevated and fufpended in the water, though in itfelf greatly heavier than that fluid; that while in a proper ftate of feparation in this manner, they remain imperceptible in all the water, and when by certain accidents they again approach one another, they form concretions like their original ones, and again fubfide in that fluid, in which they floated while in form of this imperceptible powder.
In the *folutions* of falts, the fame author obferves, that all the particles of water do not ferve to the fame purpofe; fome officiating only in the keeping the faline particles fufpended, others in the keeping them afunder, and, as barriers, preventing their reunion.
The quantity of water, neceffary to fuftain the particles of all falts in folution, is the fame, but the quantity, required to keep thofe particles from joining again, is different, in regard to every falt. Hence though a quantity of water, equal to the weight of the falt, be fufficient to the fufpenfion of its particles, yet every falt requires its own appropriated quantity of water to keep it in a ftate of folution; that is, to keep its particles from cohering together again. In fuch falts, the particles of which are not fubject to form hard concretions, fuch as the fixed falt of tartar, and the like, there requires no more water for a *folution* than is neceffary to fufpend the particles of the falt; but in thofe which readily form folid concretions, fuch as common falt, nitre, borax, and the reft, there requires a large quantity befide to act as a barrier.
The more the particles of any falt are difpofed to reunite, the more water they require to keep them in a ftate of *folution*; and hence follows a very remarkable phænomenon, which is the *folution* of feveral falts fucceffively in the fame water: this is known to be poffible, and the reafon of the whole is this, that when a given falt, requiring a large quantity of water for its *folution*, is diffolved in that water; the greater part of that water, which in this *folution* ferves only to the fecond purpofe of keeping the particles of the falt afunder, is ftill at full liberty to act as water upon another falt that fhall be thrown into it.
This, however, can be only the cafe in regard to falts which do not naturally ferment with one another, becaufe the whole procefs is difturbed by fuch a fermentation, and, in confequence of it, there is a third falt formed, which is not the fame with either of the two; and the confequence of the formation of this falt, is the precipitation of the metallic, or earthy matter, which was the bafe of one of the other falts. Thus an alkaline falt, added to a *folution* of alum, or faccharum faturni, takes up the acid of either of thefe falts, and becomes, by its mixture with that acid, a new concrete falt, and at the fame time throws down, in precipitation, the terreftrial bafe of the alum, and the metallic one of the falt of lead.
To return to thofe falts which excite no fermentation with one another. In regard to thefe, when a quantity of water has diffolved as much as it can retain of one, it will readily take in and diffolve a fecond; and the particles of this not fermenting with thofe of the falt firft diffolved, will remain fufpended, and the water which diffolves them, and which in the firft *folution* ferved only as an intermedium to keep the particles of that falt afunder, ferve as well to that purpofe, now they are impregnated with this new falt, as they did before.
The reafon hitherto given for this phænomenon was, that the particles of different falts, though fufpended in fuch manner in the fame fluid, that they were every moment coming into contact with one another, yet had no tendency from nature to cohere, or precipitate one another; but that whenever, by future accidents, they fhould be brought to concrete, they would do it feparately, each in its own pure ftate; but this reafon, though true, is an imperfect one. In thefe fucceffive *folutions* of falts in the fame water, the fecond falt produces a remarkable effect, which no body, till Mr. Lemery, feems to have taken notice of; which is, that while this is diffolved in a liquor, which before ferved as an intermedium to keep the particles of another falt afunder, it encreafes by its whole quantity the quantity of that intermedium, and becomes itfelf a fort of intermedium to the particles of the firft diffolved falt; and by this means the liquor, which had before diffolved as much as it could contain of the firft falt, now becomes able to take up fome more of it, and will, in reality, perfectly diffolve an additional quantity: this was an experiment well known, but never underftood before.
It is well known that falt of tartar does not ferment with falt petre, nor does it take any thing from this falt, or at all alter by being mixed with it, which is quite different from the effect on mixing it, as before obferved, with alum, or faccharum faturni; on this principle, and on the known property of falt of tartar being diffolved in a fmaller quantity of water than any other falt; or, in other words, of water's diffolving more falt of tartar than of any other falt, Mr. Lemery refolved on the trial, whether water, which had already diffolved as much nitre as it could contain, would not, on the addition of falt of tartar, diffolve a larger quantity of frefh nitre, than on the addition of fal armoniac, or any other falt: but what appeared very ftrange was, that after two days ftanding of a *folution* of nitre, with about a fourth part of the quantity of falt of tartar added, there was found a white powder at the bottom. The liquor being examined on this, was found to be a lixivium of falt of tartar, and the powder at the bottom, falt petre.
On adding frefh quantities of falt of tartar, new precipitations were afterwards formed, and, in fine, all the falt petre which had been diffolved was feparated. The falt petre being examined, by all trials proved true falt petre, as pure and unmixed as when put in; and the liquor being evaporated, the falt of tartar was found equally pure. Salt of tartar tried afterwards in the fame manner with *folutions* of other falts, with which it does not raife any fermentation, was found to have the fame effect, precipitating all equally out of the *folution*.
In the common precipitations of falts, fuch as alum and fugar of lead, by means of an alkali, the alkali feizes upon the acid of thofe falts, and by that means effects the thing, and therefore itfelf becomes changed into another falt, and the precipitate, robbed of that acid, is no longer the falt it was, but merely its bafe: but here the falts, both alkali and neutral, remain the fame they were before, both pure and unmixed, and the whole procefs feems only one of them taking the place of the other.
The falts which are capable of fucceffive *folutions* in the fame water, and of remaining fufpended together in it, muft be all of the neutral kind; that is, they muft be falts compofed of acids, engaged in fuch manner in the pores of their bafes, as to fill the whole, and leave no void fpaces for the penetration of other acids. But this is by no means the cafe with falt of tartar, which being wholly fpunge-like in its ftructure, readily admits all forts of acids, and ferments with them; and therefore is very capable of divefting other falts of that, on the prefence of which their natural ftate, as falts of a particular kind, depends.
Every alkali falt is, as it were, an effential falt, in part decompounded; that is, it is the earthy part of fuch falt, the acid parts of which have been driven off by fire, and when there is only fo much left, as may give the whole a faline form; for if all the acids were to be driven off, the remainder would not be an alkali, nor yet a falt, but a mere fimple earth; as is the cafe in the caput mortuum of fpirit of nitre diftilled by a retort, the refiduum from this diftillation being a mere dead earth, indiffoluble in water, and altogether different from the fixed alkali produced by burning the fame nitre with charcoal. What proves, alfo, that thefe alkalis are only the matrix of the compound falts divefted of their acids, is, that if fpirit of nitre be poured upon the alkali falt of nitre made with charcoal, true nitre is regenerated. Mem. Acad. Par. 1724.
When *folutions* of falts are congealed, the ice often affords very pretty figures; but it is to be obferved, that the fame falt does not always give the fame figures. Thus the fame *folution* of verdigreafe, frozen by means of fnow and falt, affords

affords a different figure, from what is produced by the natural cold of the air. And the former ice being thawed, and left to freeze in the same vial, did not give the same figures as at first. See *Boyle*'s Works Abridged, Vol. I. p. 168.

SOLUTION, in metallurgy, is distinguished into dry and moist. The dry *solution* is the blending imperceptibly a small quantity of a metal, or mineral, with a very large one of some other body, dry, hard, and not fluid when cold. The moist *solution* is the distributing a body through the very minutest parts of an aqueous, or in great part aqueous fluid, in such manner, that both may turn into a fluid, to appearance, homogeneous, which goes through all filters, without being detained or separated by them, and the smallest part of which contains in it a proportionable quantity of both the menstruum or dissolvent, and of the dissolved body. The *solution* of gold in aqua regia, and of silver in aqua fortis, as also that of any of the salts in water, are *solutions* of this kind. *Cramer*'s Art of Assaying, p. 194.

In the making the several *metallic solutions*, for the necessary processes in chemistry, the operator is subject to great danger in his health, from the noxious vapours. This has been an accident complained of indeed by many, but scarce attempted to be remedied or obviated by any, in a rational way, till Mr. Geoffroy, whose experiments subjected him greatly to the mischief, employed his thoughts for his own sake, as well as that of the world in general, to the effectual preventing it.

The dissolutions of the metals, in the corrosive acid spirits, are those which send out the most copious and most dangerous vapours. The exhalations of quicksilver, of antimony, and of lead and copper, are all in themselves greatly hurtful, as well as the fiery vapours of spirit of nitre, sea-salt, or vitriol; and if either of these is singly so, how pernicious must they need be in those cases, where two of them are joined together in such a manner, as that this union sends up infinitely more vapours than would otherwise arise? in this case, the utmost care is necessary to prevent the chemist from falling a sacrifice to his zeal for his discoveries.

The common way of avoiding this danger, is by making the *solution* either abroad in the open air, or in a chimney; but sometimes these cautions cannot be used, and under some circumstances they are ineffectual. This gave occasion to Mr. Geoffroy to use a method, which he afterwards proposes to the public, of stopping the rise of the vapours entirely, or at least of diminishing them so greatly, that they shall be harmless and unperceived. All that was necessary to this, seemed to him to be the contriving to cover the surface of the fluid with some body, capable of retaining those vapours, yet not capable of disturbing the operation of the menstruum on the metal; and the common expressed oils of fruits, as the oil of olives, almonds, or the like, were found capable of happily performing this effect; and that particularly, as they would easily receive into themselves the acid salts which arise in the conflict. The thing which gave this gentleman the hint of the discovery was, that in the boiling of sugars, honey, or the like substances, when there is any danger of their boiling over the vessel, the pouring in a little oil stops the swelling. In the *metallic solutions* it has the same effect; and that heightened by this good consequence, that by keeping in the fiery vapours of the acid, it returns them back upon the metal, and by this means does, in effect, add greatly to the power of the menstruum.

This method of using oil has indeed three advantages, 1. The preserving the operator from the injuries from the vapours. 2. The greatly moderating that violent rarefaction which is often of ill consequence. And 3. the same quantity of the menstruum, by this means, dissolves more of the metal. The best method of making *solutions* with this advantage is this: first wet the surface of the metal to be dissolved with water, or spirit of wine; then pour a little water, or spirit of wine, into the glass in which the *solution* is to be made, this will prevent the oil from sticking to the surfaces of either; then put the metal into the glass, and pour in the oil upon it; last of all, pour on the menstruum: this being greatly heavier than the oil, will sink to the bottom and work upon the metal, while the oil perfectly covers the whole surface. There is no need to be exact as to the quantity of the oil, but more or less is to be used, in proportion to the greater or less ebullition which the mixture is expected to make.

The air-bubbles, which arise to the surface with great impetuosity in the making of these *solutions*, are here seen to break by degrees as they enter the covering of oil, and generally are quite dissipated before they arise to the surface of it. The few of them which retain their figure till they arrive at the surface, there burst and give a slight exhalation; and one may continually see the drops of the menstruum falling back again out of the oil into it, after being deserted by the bubbles of air which had raised them so far. On the contrary, in the common way of making *solutions*, the air-bubbles push one another up to the surface, where they form a sort of skum, which continually thickens by their fresh rising and supporting one another, till it often rises over the top of the vessel. These bubbles of air seem to be formed of small parcels of air extremely condensed in the pores of the metal, which, when the particles of it are separated for *solution*, find themselves at liberty to dilute and expand, and arise to the surface in their proper form.

If it be thought necessary, in any *solution* which raises a more than ordinary quantity of vapours, to prevent the flying off of that small quantity which may escape through the oil, there is nothing more necessary than to pour a little spirit of wine upon the oil; for the acid vapours which pass the oil will then be received in the spirit, and will be dulcified in it, and instead of a disagreeable odour, will yield only a very sweet and safe one. Spirit of wine alone, used instead of oil, and poured gently on the *solution*, has very great effects; insomuch, that if used to the *solutions* in spirit of nitre, which usually send up very noxious and coarse red vapours, they by this means are made to send up only very fine light white ones, and those of a very agreeable smell: the bubbles raised in this case are very small, and usually burst before they arrive at the surface of the spirit. The only objection to this method, is, that the spirit of wine soon mixes itself with the menstruum, and there are some cases in which this may be of ill consequence to the process. Mem. Acad. Par. 1719.

SONCHUS, *sowthistle*, in botany, the name of a genus of plants, the characters of which are these. The flower is of the semiflosculous kind, being composed of a number of semiflosculės, each standing upon an embryo seed, and all contained in a general cup, which is considerably thick, and becomes of a conic figure when ripe. The embryos finally become seeds, winged with down, and affixed to the thalamus. See Tab. 1. of Botany, Class 13.

The species of *sonchus*, enumerated by Mr. Tournefort, are these. 1. The prickly *sonchus* with undivided leaves. 2. The prickly *sonchus* with leaves jagged in the manner of those of dandelion. 3. The prickly *sonchus* with undivided leaves, in shape resembling those of the lettuce, or of dipsacus. 4. The Cretic jagged prickly *sonchus*. 5. The great tree prickly *sonchus*. 6. The great creeping *sonchus*, called by many the *great creeping hawk-weed*. 7. The smooth *sonchus* with broad jagged leaves. 8. The white-flowered broad-leaved jagged smooth *sonchus*. 9. The smooth *sonchus* with leaves divided into numerous fine segments. 10. The lesser smooth *sonchus* with less jagged leaves. 11. The smooth narrow-leaved *sonchus*. 12. The narrow-leaved sea-*sonchus*. 13. The smooth *sonchus* with poppy leaves. *Tourn.* Inst. p. 474.

The common *sowthistle* is greatly recommended by authors as a refrigerant and attenuant. It is prescribed by many of the old physicians in stranguries, and other disorders of the urinary passages; and is ordered externally, in cataplasms, in all kind of inflammations.

SONTAGE, in our old writers, a tax of forty shillings laid upon every knight's fee, according to Stow, p. 284. *Blount*, *Cowel*.

SOOT (*Cycl.*)—This is an excellent manure, particularly for cold lands, which have been long over-run with moss; but sea-coal-*soot* is much better for this purpose than wood-*soot*. They usually allow forty bushels to an acre, but some lands require more. It produces an extremely fine and sweet grass, and destroys weeds of all kinds. *Mortimer*'s Husbandry.

The chemical analysis of *soot* shews us, that it is composed of several parts; 1. a fetid, oily, bitter spirit. 2. Water. 3. A sharp volatile alkaline oily salt. 4. A sharp alkaline fat oily spirit. 5. A fetid black bitter inflammable, and almost caustic oil, mixed with an oily salt. 6. A true sal armoniac. And 7. a black fixed earth.

Wood-SOOT has been long known as a good medicine in many cases, but the principles upon which it acted as such were never well understood, till Boerhaave gave a regular analysis of it. The directions he gives for the process are these.

Choose the blackest and driest *wood-soot* from the chimney of an oven, where nothing is baked but bread, and nothing burnt but vegetables; gather this in a dry day, and fill with it a glass retort almost up to the neck; clean the neck of the retort, and luting on a receiver, give a fire of a hundred and fifty degrees, and keep it up equably, a large quantity of transparent water will come over with considerable violence. When no more water will come over, cleanse the receiver, and raising the fire to a little above two hundred degrees, there will then come over a whitish fat liquor; this also comes over with great violence, and the fire must be gradually encreased, till no more of this will come. Change the receiver, and raise the fire to a yet greater degree, and a yellow, copious, volatile salt will come over, and stick all over the sides of the new receiver. When no more of this salt will arise, encrease the fire to the utmost that sand can give, and with a heat of suppression there will arise a black thick oil; when this is all come over, and the vessels cooled, there will be found in the neck of the retort a salt, which could be raised no higher, even by that violent fire; and in the

the bottom of the retort there remains a black feculent matter, the upper furface of which is covered with a white faline cruft, which, both in figure, colour, and the ftructure of its ftriæ, refembles the common fal armoniac. If the milky liquor be rectified, it affords a very penetrating volatile fpirit, and fome fharp volatile falt.

Here we are taught what the agitation of an open fire can move, change, expel, and drive through the air by burning; firft in the form of fmoak, then of flame, and laftly of exhalation, and how high it is able to carry them; for a chimney is a kind of ftill-head, converging in an open top, and *foot* is often carried up thirty or forty feet, or more, to the top of thefe, and after this a black fmoak is difcharged out of the orifice, which difperfes in the air, and finally feems to vanifh.

This fmoak and *foot* confift of feveral parts; as 1. a fetid, oily, unpleafant bitter fpirit, refiding in the water that firft comes over, and is afterwards found difperfed alfo through all its other parts; this fpirit feems to be the oily and more fubtile part of the vegetable, acted on by the force of fire. 2. A water, which is here contained in great plenty in this fpirit; in the firft limpid, and in the fecond milky liquor, as alfo in the faline fpirit, and the volatile falt itfelf, and even in fome degree in the oil. This water can fcarce be feparated pure by any art, being always impregnated with the bitter tafte and naufeous fmell of the fpirit. 3. A fharp volatile alkaline oily falt, which firft comes over, and fticks to the fides of the receiver. From this principle we are well affured, that fuch a volatile alkaline falt always ftrongly impregnates the whole air, where wood fuel is burnt. 4. A fharp alkaline fat fpirit, confifting of the falt juft now mentioned diffolved in water, and fo refembling fpirit in fluidity, pungency, volatility, and the other qualities. 5. A fetid black bitter naufeous, and almoft cauftic oil, mixed with an oily falt. 6. A true fal armoniac, raifed to the neck of the retort, and covering the furface of the black matter left at its bottom. If this falt be carefully collected and feparated from the alkaline kind, it proves to be a perfect and genuine fal armoniac; it is of a whitifh colour, fomewhat tranfparent, and makes no effervefcence with acids, and if mixed with fixed alkalis, it eafily yields a volatile falt, wholly agreeing with that from the commom fal armoniac; whence by the by it is evident, that all fal armoniac owes its origin to *foot*. 7. The laft fubftance found in *foot*, is the remaining black earth left at the bottom of the retort: this has an oil which tenacioufly adheres to it, and when this is driven off in a ftrong open fire, there remains a white calx.

By this accurate analyfis of *wood-foot*, we learn what parts of vegetables are volatile, and fly off by an open fire, and what are fixed and remain behind, and finally, what fire throws off from vegetables into the air; and hence, among other things, we may learn that even earth, which appears fo very fixed in the fire when feparated from the other principles, yet when mixed with them is, by the force of fire, thrown up to the height of forty feet, and more, in the air; whence it afcends to yet greater heights, and finally difperfes in form of a thin cloud.

Hence we may alfo learn that *foot*, which contains fo many active principles, muft be qualified for a powerful medicine. Pills of dry *foot* are found very beneficial in all cold diftempers; the volatile falt of *foot* poffeffes the virtues of the volatile falts of animals. The falt which rifes laft is recommended greatly by Hartman for giving relief in cancers; and this is very probable, fince fal armoniac of the common kind, properly applied, is known to be of great ufe in cafes of running cancers. *Soot* of different fuels is not to be fuppofed all to poffefs the fame virtues; that of pit-coal is found to be a fubftance of a very different kind from that of wood, and that of the common turf, or peat, and of the oak wood, have alfo been found, on experiment, to be very different. Boerhaave very juftly obferves, that the *foot* from kitchen-chimneys, where the fmoak muft have been impregnated with the effluvia of the victuals, muft be very different from pure *wood-foot*. *Boerhaave*'s Chemiftry.

The tincture of *foot* is in ufe; and Dr. Cheyne recommends it as a great and fudden relief in vapours. Nat. Meth. of curing Difeafes.

SOPHORA, in botany, the name given by Linnæus to a genus of plants called by Dillenius, in his Hortus Elthamenfis, *ervi fpecies*; the characters are thefe. The perianthium is fhort and campanulated; it confifts of one leaf, divided into five obtufe fegments at the end. The flower is of the five-leaved papilionaceous kind. The vexillum is oblong and ftrait; it grows broader as it approaches the apex, and is bent back at the edges. The alæ are two; they are oblong, of the length of the vexillum, and appendiculated at the bafe. The carina confifts of two petals, of the fize of the alæ, the under edges of which ftand near together, fo that they form a fort of boat. The ftamina are ten diftinct parallel fubulated filaments; they are of the fame length with the flower, and are hid in its carina. The antheræ are fmall and affurgent; the germen of the piftil is oblong and cylindric; the ftyle is of the length and fituation of the ftamina; and the ftigma is obtufe. The fruit is an extremely long and flender pod, it contains only one cell, and is marked with protuberances where the feeds are contained. The feeds are numerous, and of a roundifh figure. This genus of plants agrees with the other papilionaceous and diadelphous genera, except that in this the ftamina are diftinct and feparate. *Dillen.* Hort. Elth. p. 112. *Linnæi* Gen. Plant. p. 177.

SOPHRONISTÆ, σωφρονισταὶ, among the Athenians, were ten officers appointed to take care that the young men behaved themfelves with fobriety and moderation. *Potter*, Archæol. Græc. l. 1. c. 15. Tom. I. p. 84.

SOPHRONISTERIUM, σωφρονιστήριον, among the Athenians, a houfe of correction like our Bridewell. *Potter*, Archæol. Græc. l. 1. c. 25. Tom. I. p. 130.

SOPIO, a name ufed by fome of the old writers for opium, from its foporific virtue.

SOPORARIÆ *arteriæ*, a name given by fome authors to the carotid arteries.

SOPOROUS (*Cycl.*)—SOPOROUS *difeafes*, a term by which medical writers exprefs the *lethargy* and *coma*, and fome others even the *carus* and *apoplexy*.

The firft of thefe, the lethargy, is an idiopathic affection, depending on a congeftion of blood about the head, whence there foon arifes a ftafis both of that and the other humors; the confequence of which is an univerfal oblivion, or forgetfulnefs of all things. The coma is a fymptomatic *foporous* affection, ufually complicated with deliriums, and taking its origin from a reftriction of the fluids about the head in acute fevers. This is the generally received fenfe of the moderns, as to thefe difeafes, though fome invert the meaning of the words, and make lethargy fignify a fymptomatic affection attending perfons in fevers; and the coma to be the idiopathic difeafe, particularly the fleeping coma. To thefe fome alfo add the carus, which they fay is a flighter kind of lethargy; while others will have that difeafe to be a more violent diforder than the lethargy, and of a middle nature between that and the apoplexy, or little better than the laft. *Junker*'s Confp. Med. p. 666.

Signs of them. A lethargy is ufually prefaged by an univerfal laffitude and inaptitude to motion, and a vertigo, or tremor in the head; or an intenfe pain in its hinder part; by a continual inclination and defire to go to fleep, and fleeping more found than ufual; and finally, by a ringing in the ears, and a general hebetude or dulnefs of the fenfes. When prefent, it is known by the patient's falling into a particularly found fleep, out of which it is very difficult to wake him, and when awaked he is wholly forgetful, both of himfelf, and of every thing about him, and has an immediate propenfity to fleep again; the pulfe, refpiration, colour, and heat of the body, are all the while nearly the fame as in health; and when there is a fever attendant on it, it is ever a very flow, and fcarce fenfible one. The coma is of two kinds, the fleepy and the waking, or *coma vigil.* In the fomnolent, or fleepy coma, the patients fall into a long and found fleep, but that not fo profound as in the lethargy; for in this cafe, though they be immoveable, yet they are much more eafily waked than in lethargies, and are not fo perfectly forgetful of all things when waked, as they are in that difeafe. In the coma vigil, or wakeful coma, the patient has an eternal propenfity and defire to fleep, but cannot really get to fleep; with this he is ufually delirious, and commonly keeps his eyes fhut, but is all the time very quick of hearing whatever is fpoken in the room, and opens his eyes immediately on being touched; and fometimes their delirium proceeds fo far, that they endeavour to get out of the bed, and to do feveral mad actions.

Perfons fubject to them. Lethargies principally affect fat people, who are of a fanguineo-phlegmatic habit, and particularly fuch as are advanced in years, and live upon rich and moift diets, and have accuftomed themfelves to fleeping after dinner. Old people alfo, who have been fubject to catarrhs, whether of the head or breaft, and fuch as have been long ufed to have iffues, and have clofed them up, or to regular cuppings at certain feafons of the year, but have omitted them, on account of their advanced age, ufually fall into it. Thofe alfo who have been much ufed to tobacco, whether fmoaked or taken in fnuff, and have fuddenly left it off, very often alfo fall into this difeafe, or into apoplexies. There are alfo many other caufes, from which old men are fubject to lethargies, fuch as long waking, cares and troubles upon the fpirits, the ufe of narcotic medicines, drunkennefs, contufions, or heavy blows upon the head, and, as fome affirm, the being for a long time together expofed to the rays of the moon. Infants alfo, which are fat, are fubject to the fame difeafe, from the ftriking back of any watery humor.

Comas ufually happen to people in acute malignant fevers, and are preceded by violent pains in the head, and raging deliriums, and are very often owing to the improper ufe of opiates, and ftupifying medicines. *Junker*'s Confp. Med. p. 670.

Prognoftics in them. Old perfons, who are fubject to frequent fleepinefs, unlefs they change their courfe of life, and ufe a coarfer

coarfer diet and more exercife, ufually fall into fatal lethargies. In perfect lethargies, in which the patients cannot be wakened at all, they ufually die between the fourth and the feventh day, unlefs an eruption of fome matter from the nofe or ears happen; which is not unfrequently the cafe in perfons who fall into this difeafe, after violent blows on the head. The coma is much the fame in its prognoftics as the lethargy; but in this a cold fweat ufually prefages immediately approaching death. It is much better that a phrenitis fhould happen to perfons in a lethargy, than that a lethargy fhould happen to thofe in a phrenitis.

Method of cure. In a lethargy the fenfes are to be roufed, and the humors deduced from the head to the lower parts by ftimulating glyfters, and acrid fuppofitories, by ligatures on the oppofite parts, by frictions, blifters, and finapifms, or fuch cataplafms as bring on heat and rednefs of the parts, applied to the foles of the feet and the palms of the hands; as alfo by twitching off the hairs in very fenfible parts, by applying volatile falts to the nofe, by pricking with a needle, and by loud calling: and in plethoric habits, immediately after the clyfter, a vein fhould be opened, and after that leeches applied to the temples; and internally, powders of nitre and cinnabar, with the gentle alexipharmics, are to be given; and all forts of camphorated medicines are proper to be applied externally, after fhaving the head. In many cafes, crudities in the primæ viæ have a great fhare in bringing on thefe difeafes, and in fuch vomits and brifk purges are very proper.

In a coma, whether it be of the fomnolent, or wakeful kind, the fever, which is the primary difeafe, is firft to be regarded; but with the antifebrific medicines, the nitrous and cinnabarine fhould be joined, and the camphorated ones ufed externally.

Prefervatives againft them. Every prefervative muft tend to the taking off what may prove the caufes of thefe diforders. For this purpofe, in old perfons of mucous habits, the matter muft be by all poffible means derived from the head, and carried off by fome fafe way. In this intention, brifk purges of jalap and colocynth, and for thofe of very fanguine habits, of black hellebore, are to be given every quarter of a year. To thefe fhould be added the bitters, and fulphureous medicines, with the gum refins, in form of pills: thefe fhould be taken regularly at the equinoxes; and a proper diet muft be obferved, namely, drier foods muft be principally eaten, and the fpices frequently ufed, and the patient advifed not to eat too heartily. Roafted meats, in general, are better than boiled; and wine fhould be drank in moderation, and fome of it impregnated with bitters. *Junker*'s Conf. Med. p. 678.

SOPRANO, in the Italian mufic, fignifies the treble.

SORA, in botany, the name given by the people of Guinea to a kind of fhrub which they ufe in medicine, boiling it in water, and giving the decoction in cafes of pain of any kind.

The leaves of this fhrub are of the fize and fhape of thofe of fena; they ftand upon fhort footftalks, and are woolly underneath. Philof. Tranf. N° 231.

SORBUS, the *fervice-tree*, in botany, the name of a genus of trees, the characters of which are thefe. The flower and fruit refemble thofe of the cratægus, but differing, in that the leaves are winged as thofe of the afh.

The fpecies of *forbus*, enumerated by Mr. Tournefort, are thefe. 1. The common *fervice*. 2. The cultivated *fervice* with a large red fruit of a turbinated form. 3. The cultivated *fervice* with large turbinated pale-red fruit. 4. The cultivated *fervice* with a reddifh middle-fized turbinated fruit. 5. The cultivated *fervice* with a reddifh middle-fized oval fruit. 6. The cultivated *fervice* with a fmall reddifh turbinated late-ripening fruit. 7. The cultivated *fervice* with fmall turbinated fruit. And 8. the wild *fervice*, or *forbus aucuparia*. *Tourn.* Inft. p. 633.

SORE, among fportfmen, denotes a buck of the fourth year.

SOREL, in the language of fportfmen, a buck of the third year. See the article BUCK.

SOREL, in botany. See SORREL.

SOREX, in zoology, the name of a fpecies of wild or fieldmoufe, called the *dormoufe*, or *fleeper*. There are two kinds of this creature, a larger and a fmaller.

The larger *dormoufe* is nearly of the fize of the common rat. Its colour is a brownifh grey, like that of the common moufe, but variegated with fomewhat of a reddifh caft on the fides, and on the head. The ears are large and fmooth; the belly is white; and the inner part of the legs, and the lower part of the tail, efpecially toward the extremity, are of the fame colour. The noftrils and the feet are red; the tail is all over hairy, and is terminated by a thick tuft of white fur. The eyes are large and prominent, and of a fine jetty fhining black. The beard is partly white, and partly black. Round about the eyes, and round the ears, there is a fine blacknefs; the upper part of the tail is alfo black. The fmell of this creature is the fame with that of the moufe, and its dung is of the fame kind. It lives in caverns underground, and fleeps all the winter, as fome affirm. It feeds on vegetables, and is particularly fond of hazel-nuts, which it ufually hoards up, when ripe, for a fcarcer feafon. *Ray*'s Syn. Quad. p. 219.

The fmaller kind is much more common than the larger one. This is of the fize of the common moufe, and in different countries varies much in colour. In Italy Mr. Ray obferved it all over of a reddifh tawney on the upper part, except the end of the tail, and all its under part white, the tail only excepted; the tail covered with long and thick-fet hairs, and looking fomewhat like a fquirrel's. The eyes are very black and prominent. Thofe which the fame author obferved in England were lefs of the reddifh hue on the back, and were not white under the belly, but only on the throat; neither had they the white tip at the end of the tail. Poffibly the Italian and Englifh may be really diftinct fpecies. This creature feeds on nuts and other fuch fruits. It retires into caves in winter, and fleeps much, but not through the whole winter, as has been fuppofed, for it lays up its winter-provifion in its hole in autumn, and feeds on it at that time. *Ray*'s Syn. Quad. p. 220.

The *forex*, according to the Linnæan fyftem, makes a diftinct genus of animals; the diftinguifhing character of which, is, that its dentes incifores, or cutting-teeth, are two in number, and are ferrated, or notched on each fide. *Linnæi* Syft. Nat. p. 40.

SORGLUM, in the materia medica, the name of the grain of the *milium arundinaceum*, called *Indian millet*. *Dale*'s Pharm. p. 262.

SORNI, a name given by fome of the chemical writers to iron. *Caft.* Lex. Med.

SORRANCE (*Cycl.*)—SORRANCE-*water*, a name given by our farriers to a folution of vitriol and fome other ingredients in vinegar, a medicine much efteemed in many of the difeafes of horfes: it is prepared in the following manner.

Take Roman-vitriol and roach-alum of each an ounce and half, verdigreafe an ounce, copperas two ounces; reduce all thefe to powder together, and put them into a two-quart bottle, into which pour a quart of the ftrongeft and beft wine-vinegar; this is to be fet in balneo mariæ. The fhort way of doing which by the farrier, is this: he puts a wifp of hay into the bottom of a kettle, and then tying fome pieces of lead or iron about the neck of the bottle, to make it heavy enough to fink in water, it is fet upon the hay fo, as to ftand very upright; then three notches are cut lengthwife in the cork to give paffage to fome of the vapours when the bottle is heated, that it may not burft. When every thing is thus prepared, fo much cold water is to be put into the kettle, that the neck of the bottle may ftand two or three inches above it; the kettle is then to be fet over the fire, and the water is to be made to boil, and kept boiling about half an hour, the bottle being at times taken out, and thoroughly fhaken. When the falts are thus thoroughly diffolved in the vinegar, the whole is to be kept for ufe.

The method in which they ufe it is this. Take an earthen pan, which will hold about twelve quarts, let this be filled with urine that has been made by found, healthy, and young perfons; the ftaler the urine is, the better it is for ufe, and it ought indeed always to ftand, at leaft, three weeks before it is ufed. It is proper for the farrier, therefore, always to keep a quantity of this ready, and when the *water* is to be ufed, half a pint of it is to be mixed with a quart of the urine, or if it be required ftronger, more of the *water* is to be added: thefe are to be thoroughly mixed together, and the legs, or other affected part of the horfe, bathed with it with foft rags twice a day.

The virtues of this *water* are highly extolled; it is faid to cure the malanders in two, or three times dreffing; it is alfo a fovereign remedy for the mange, either dry or wet, and for the rat-tails, fcratches, gourded, or fwelled legs and heels; and it alfo cures horfes when the greafe is fallen into their heels, as the farriers exprefs it. The farcy is alfo faid to be often cured by a long continuance in the ufe of it, purging the horfe two or three times, at different diftances of time, during the time of his being under cure by the *water*. They alfo find it a good cleanfer and healer of foul ulcers, and that it prevents the breeding of proud-flefh and worms in wounds, and drives away a flux of humours that were falling upon any part. They ufe it alfo in clefts and cracks of the heels, and in windgalls, efpecially in the prevention of the laft by its repellent qualities. The green *water* alone is an excellent remedy for fiftulas, cankers, and the galled backs of horfes; difpofing fuch *forrances*, as they are called, not to fefter, rot, and grow worfe, as all greafy and oily medicines do, but cleanfing them, and laying the way to a very found and ftanding cure.

SORREL, *acetofa*, the name of a genus of plants, the characters of which are thefe. The flower is of the ftamineous kind, being compofed of a number of ftamina arifing from a fix-leaved cup. The piftil, which is furrounded by thefe, finally becomes a triangular feed, wrapt round in a cup: this is compofed of three of the fix leaves of the cup, the other three withering away.

The fpecies of *forrel*, enumerated by Mr. Tournefort, are thefe. 1. The common meadow-*forrel*. 2. The white-flowered

flowered meadow-*forrel.* 3. The meadow-*forrel* with curled leaves. 4. The great mountain-*forrel.* 5. The Pyrenean *forrel* with very long and narrow leaves. 6. The mountain-*forrel* with a broad and roundifh leaf, fomewhat refembling that of arum. 7. The mountain-*forrel* with leaves like thofe of the lemon-tree, and with branched twigs. 8. The mountain-*forrel* with undulated leaves, and not branched twigs. 9. The dwarf mountain-*forrel* with the fagopyrum leaf. 10. The mountain-*forrel* with knotty points. 11. The tuberofe-rooted *forrel.* 12. The *forrel* with pale green arifarum leaves. 13. The mountain-*forrel* with narrow arrow-headed leaves. 14. The marygold-leaved *forrel.* 15. The atriplex-leaved fhining *forrel.* 16. The great Italian *forrel* with round glomerated feeds. 17. The lanceolated field-*forrel.* 18. The tall narrow-leaved lanceolated, or fheep's *forrel.* 19. The narrow-leaved creeping lanceolated *forrel.* 20. The fmall *forrel* with leaves not lanceolated. 21. The Cretic *forrel* with prickly feeds. 22. The fmall Cretic *forrel* with utriculated feeds. 23. The bafil-leaved *forrel.* 24. The American *forrel* with leaves ftanding on very long foot-ftalks. 25. The roundifh-leaved tree-*forrel.* 26. The round-leaved garden-*forrel.* 27. The round-leaved Alpine *forrel.* 28. The round-leaved creeping Yorkfhire *forrel* with leaves finuated in the middle. 29. The creeping fhielded-*forrel.* 30. The little erect *forrel* with multifid leaves. 31. The trifid-leaved Indian *forrel.* *Tourn.* Inft. p. 502.

Sorrel feeds are found to contain a vaftly larger proportion of the active principles this plant abounds with, than either the leaves or the roots. They are efteemed aftringent, and good in diarrhœas, dyfenteries, and hæmorrhages.

We much neglect this plant, becaufe it is common; yet this plant alone has very often proved a remedy for the fcurvy. Mr. Morin, of the Academy of Paris, who in the Hotel Dieu had many hundred fcorbutic patients, cured the greater part of them only by *forrel* boiled and eaten with eggs.

Wood-SORREL, *lujula*, in medicine, is a very grateful acid; in fevers it quenches thirft, and takes off the heat of the ftomach. It is recommended in fevers of all kinds, and the fcurvy; alfo in obftructions of the liver and of the vifcera. It is fometimes given in decoction in fevers, and the expreffed juice is mixed with the juices of the other antifcorbutic plants againft the fcurvy.

Externally, it is extolled againft inflammatory eruptions of all kinds in decoction, which is to be ufed by way of fomentation. There ufed to be a fyrup, but, at prefent, only a conferve of this plant is retained in the fhops.

SORREL, in the manege, is ufed for a reddifh colour. The mane ought to be red, or white, in a horfe of this colour. It is diftinguifhed, according to the degrees of its deepnefs, into a *burnt forrel,* and a *bright,* or *light forrel.* Generally fpeaking, it is a fign of a good horfe.

SORY, in natural hiftory, the name of a foffile fubftance, much fpoken of by the antients, but fuppofed to be now loft: this, however, proves to be an error, for it is plentifully produced in the eaftern parts of the world, and is in common ufe there, only under another name; neither indeed is it peculiar to that part of the world, though the inaccuracy of the late writers of foffils has made them overlook or miftake it.

It is a firm and not brittle fubftance, though of a fpungy and cavernous ftructure, and is confiderably heavy. It is found in maffes of no regular fhape or fize, fome being roundifh, others angular or flatted, and fome of the fize of a wallnut, others of many pounds weight. It feels very harfh and rough to the touch, and is covered with no inveftient coat or cruft, but fhews its natural furface, which is always corrugated or wrinkled, and ufually full of fmall protuberances and cavities, and when broken, is found to be of a rugged and fpungy ftructure within.

Its natural colour is a rufty black, but it is fometimes reddifh, and fometimes bluifh; and is commonly ftained, in different places, with fpots of a bluifh or ruft colour, when black; and of a greenifh hue, when it is of a reddifh colour: in the places where it is free from thefe, it is ufually fomewhat bright and fparkling. It is of an acrid and difagreeable tafte, and of a ftrong and naufeous fmell: put into the fire it burns to a deep purple, and if boiled in water a great part of it becomes diffolved in it; and this may again be feparated from the water by evaporation and cryftallization, and then appears in the form of pure blue vitriol, forming regular rhomboidal cryftals, and tinging iron to a copper colour, on being firft wetted, and then rubbed upon it. *Hill's* Hift. of Foff. p. 606.

It is found in many parts of the Turkifh dominions, particularly in Gallo-Græcia; as alfo in fome parts of Germany. In this country it is boiled for the blue vitriol it contains. In Turky it is mixed with lime, and made into a pafte with water, which is laid on fuch parts of the body as they would eradicate the hair fiom, and effects that purpofe in a very few minutes. In the eaftern nations, where it is thus ufed, it is known by the name *rufma.*

The antients ufed it externally to take off pimples, and put a piece of it into a hollow tooth, as a remedy for the tooth-ach. There can be no doubt of their *fory* being the fame fubftance with this; fince Diofcorides has defcribed it to be blackifh in colour, full of fmall cavities, moift on the furface (as ours always is in moift weather) and of a difagreeable tafte and fmell.

This fubftance, as alfo the chalcitis, mify, and melanteria, are all properly ores of vitriol, the particles of thofe falts being fo perfectly blended in them, as not to be at all diftinguifhable to the naked eye, yet being always regularly feparable from them by water, which is to the faline ores what fire is to thofe of the metalline kind. *Hill's* Hift. of Foff. p. 607.

SOSPIRO, in the Italian mufic, a paufe or reft, equal to the time of a crotchet. See the articles PAUSE, REST, CHARACTER, *Cycl.*

Canone al SOSPIRO. See CANONE *al fofpiro.*

SOSTENUTO, in the Italian mufic, denotes that the found is to be held out in an equal and fteady manner for the whole time of the note. Thus they fay *arcate foftenute.* See *Corelli,* Concerto 8.

SOTIRELLA, a name given by fome to a compound medicine, in form of a hard mafs, and confifting of opium and fome other narcotics, with camphor, wood-foot, and nutmeg. It is defcribed in the Auguftan Difpenfatory, and is intended to be put into hollow teeth, as a remedy for the tooth-ach.

SOUGH, otherwife called an *addit,* in mineralogy, is a paffage like a vault cut out under the earth, to drain the water from the mines. *Houghton's* Compl. Miner in the Explan. of the Terms.

SOUL (*Cycl.*)—SOUL-*fcot,* a certain fee paid by our Saxon anceftors to the prieft on opening a grave. See the article BURIAL.

SOUL-*trees,* in mining. See the article STOWS.

SOUND (*Cycl.*)—Mr. Euler [b] is of opinion, that no *found* making fewer vibrations than 30, or more than 7520 in a fecond, is diftinguifhable by the human ear. According to this doctrine, the limits of our hearing, as to acute and grave, is an interval of eight octaves.—[[b] Tentam. Nov. Theor. Muf. cap. 1. fect. 13.]

SOUND, in the manege. A horfe is faid to be *found* that does not halt. When a jockey fells a horfe, he warrants him *found* hot and cold; that is, that he does not halt either when you mount him, or when he is heated, nor yet after alighting, when he ftands and cools.

SOUNDING (*Cycl.*)—SOUNDING *the pump,* at fea, is done by letting fall a fmall line, with fome weight at the end, down into the pump, to know what depth of water there is in it.

SOUR *land,* in agriculture, a term ufed by the farmers to exprefs a cold and fomewhat wet clayey foil.

This muft have its tilth according to its ftate and condition, when they fet about it. If it have a ftrong fwarth upon it, then they give it a fallow, by turning it up when the fun is in Cancer: this they call a fcalding fallow, and efteem it of great ufe, becaufe it kills the grafs roots, and makes the land fine; but if it be light, and have but a thin fwarth, they leave it for a cooler tillage, and plow it early in the year, when their clay is fallowed.

Pigeon's dung and malt-duft are the moft proper manures for this foil. The malt-duft is to be fown with the winter-corn, and plowed in with it, for then it lies warm at the roots of the corn all winter. *Plot's* Oxfordfhire, p. 246.

SOURDON, in zoology, the name of a bivalve fhell-fifh found on the coaft of Poitou, and other places. It is a fmall fifh, its length being little more than an inch, and its breadth about three quarters of an inch. Its fhells are both confiderably convex, the outer furface is deeply furrowed, but the infide is perfectly fmooth. The fifh buries itfelf lightly in the fand, and has a pipe of communication, which it raifes to the furface; but as this creature never buries itfelf deep, the pipe is neceffarily very fhort; but they are cut into feveral fegments at the extremity, and appear as it were fringed, and have feveral hairs growing from thefe fegments. The *fourdon* is capable of a progreffive motion by means of a limb, fomewhat refembling that of the other chamæ; but more than any approaching to the nature of a leg, as it in fome meafure reprefents, in miniature, a human leg with a clumfy boot upon it: by means of this limb the creature can eafily bury itfelf in the fand, or rife up out of it, or move horizontally on the furface, and that as well backwards as forwards, and that with more fwiftnefs than could be well fuppofed. Mem. Acad. Par. 1710.

SOURIS, in the manege, is a cartilage in the noftrils of a horfe, by means of which he fnorts. See SNORT.

The cutting of this cartilage is called in French *effourifter.*

SOUTHERNWOOD, *abrotanum,* in botany, the name of a genus of plants, the characters of which are wholly the fame with thofe of wormwood, and the plants are only to be diftinguifhed by their very different general face and appearance.

The fpecies of *fouthernwood,* enumerated by Mr. Tournefort, are thefe. 1. The broad-leaved fcentlefs *abrotanum.* 2. The great narrow-leaved male *abrotanum.* 3. The greateft narrow-

narrow-leaved male *abrotanum*. 4. The lesser narrow-leaved male *abrotanum*. 5. The field-*abrotanum* with white stalks. 6. The broader-leaved field-*abrotanum*. 7. The field-*abrotanum* with red stalks. 8. The hoary field-*abrotanum* with the carline smell. 9. The low *abrotanum* with very large yellow tufts of flowers. 10. The sweet-scented flax-leaved *abrotanum*. 11. The Spanish *abrotanum* with pontic wormwood leaves. 12. The sea Spanish *abrotanum* with thick shining and rigid leaves. 13. The lightly hoary male *abrotanum* of Surinam. And 14. the tall hoary *abrotanum* with very thick-set leaves. *Tourn.* Inst. p. 458.

Southernwood is an attenuant, and recommended by some in suppressions of urine, a drachm of it in powder being the dose. Its decoction is good for recovering the hair when fallen off; and its juice is said to cleanse and heal old ulcers. The leaves of this plant dried and powdered, or given in a strong infusion, are good in all obstructions of the liver and spleen; they are also of considerable virtue as antihysterics, and are given in nephritic cases. The good women give the expressed juice, of the tender tops of the plant, as a remedy against worms, and that with success. There are accounts of persons being cured of jaundices solely by the same medicine. Matthiolus recommends the leaves dried, and taken in powder, as a remedy for the fluor albus.

Female SOUTHERNWOOD. See the article SANTOLINA.

SOUTHING, in navigation, the difference of latitude a ship makes in sailing to the southward.

SOW, in the iron works, the name of the block or lump of metal they work at once in the iron-furnace. The size of these *sows* of iron is very different, even from the same workmen, and the same furnace. These furnaces having sandstone for their hearths and sides, up to the height of a yard, and the rest being made of brick, the hearth, by the force of the fire, is continually growing wider; so that if it at first contains as much metal as will make a *sow* of six or seven hundred weight, at last it will contain as much as will make a *sow* of two thousand weight. *Ray's* English Words, p. 126.

SOW, in zoology. See the articles HOG and SUS.

SOW-*bread*. See the article CYCLAMEN.

SOW-*thistle*, in botany. See SONCHUS.

SOWING (*Cycl.*)—One very great article in *sowing* to advantage, is to know exactly at what depth the seed may be planted, without danger of burying it. Seed is said to be buried, when it is laid at a depth below what it is able to come up at. Different sorts of seeds come up at different depths, some six inches, or more, and others will not bear to be buried at more than half an inch. The way to come at an accurate knowledge of the depth, at which every seed will come up best from the *sowing*, is by making gages in the following manner. Saw off twelve sticks of about three inches diameter, bore a hole in the end of each stick, and drive into each a taper peg; let the peg in the first stick be half an inch long, the next an inch, and so on, every peg being half an inch longer than the other, till the last is six inches long: then in that sort of ground, in which you intend to plant, make a row of twenty holes with the half-inch gage, put therein twenty good seeds, cover them up, and then stick the gage at the end of that row. Proceed in the same manner with the eleven other gages, making the holes in the same row all with the same gage, and sticking it at the end of the row: when the seeds begin to appear, it will be easy to see at what depth they come up best, by observing the most flourishing row, and taking up the gage at the end, and seeing what is its length.

By this means we not only know what is the depth in that sort of ground, at which this sort of seed will come up best, but also we are able to judge of the nature of the seed; for by observing how many of the twenty seeds that were *sown* come up, and how many fail, it is easy to calculate how much bad seed there is among any given quantity, and to allow properly for it in the *sowing*, that the field may be neither overstocked with plants, nor too bare of them. The farmer often sustains great losses by *sowing* bad seed, or by burying good seed, and both might be effectually prevented, by making these easy trials. One caution is to be observed in this, that it is not proper to *sow* the seeds of all plants at the greatest depths at which they will come up, because in wheat, and some other grain, a moist ground will rot the roots at this depth. Experience alone, added to these rules, can perfectly instruct the farmer in the certain way of succeeding; the nature of the land, the manner how it is laid, either flat or in ridges, and the season of planting, must all be considered.

The quantity of seed is to be different also, according to the manner of the *sowing*. The proper quantity to be drilled into an acre, is much less than must be *sown* in the common way; not because the hoeing will not maintain as many plants as the other way, for, on the contrary, it will maintain many more, but the difference is upon many other accounts, as that it is impossible to *sow* it so evenly by hand as the drill will do. For let the hand spread it never so exactly, which yet is difficult enough to do with some seeds in windy weather, yet the unevenness of the ground will alter the situation of the seeds, the greatest part of them rebounding into holes, and the lowest places, or else the harrows, in covering, drawing them down thither; so that these low places may have ten times too much seed, and the highest may have much too little, or even none of it, and this inequality lessens in effect the quantity of the seed, because fifty seeds, in the room of one, will not produce so much as one will do; and where they are too thick, without being in these clusters, they cannot well be nourished, their roots not spreading to near their natural extent, for want of hoeing to open the earth, and give them way. In the common way of *sowing*, some of the seeds are buried out of all hope of ever coming up again, and some others are left naked upon the surface, where they become the food of birds, and of vermin: as so many must, therefore, perish in the common way of *sowing*, and so few can be lost in the way by drilling, there is plain reason why the seed, necessary to *sow* any given quantity of ground, should be much less for the drill-way, than for the other. The farmers, in general, know nothing of the proper depth at which they should *sow* their seed, nor of the difference in quantity that is to be observed in different circumstances; they allow the same quantity to an acre of rough ground, as they do to an acre of fine, and forget that what is too little for one, may yet be too much for the other; it is all mere chance-work, and they put their confidence in good ground, and a large quantity of dung to cover their errors.

The farmers in Wiltshire allow more corn for the *sowing*, than in any other part of England; they use sometimes eight bushels of barley to an acre, so that if it produce four quarters for an acre, there is but four grains for one encrease. This is sown on land plowed once, and double dunged, the seed only harrowed into the hard and stale ground, so that it is very probable that not so much as two bushels out of the eight take place, or come to any thing. Sometimes, in a very dry season, an acre scarce produces four bushels at the harvest.

Instead of all this uncertainty and loss in the common way, in drilling all the seed lies just at the same depth, not one grain of it being placed deeper or shallower than the rest. As none of the seeds, therefore, can be lost by being buried, or by being exposed on the surface to vermin, no allowance is to be made for these accidents; all that is to be allowed for in the *sowing*, is the mischief that may happen from the worm, the frost, or the like unavoidable accidents, common to all seeds.

When a man has (by the use of the gages, and the growth of the seeds planted in the rows marked by them) proved the goodness of the seed, and found the depth it is to be planted at, he is to calculate what number of seeds a bushel, or any other weight or measure, contains; for one bushel, or one pound of small seed, may contain double the number of seeds of a bushel, or a pound of large seed of the same species. This calculation is made by weighing an ounce, and then calculating the number of seeds this ounce is composed of; then weighing a bushel, and multiplying the number of seeds in an ounce by the number of ounces in the bushel, and the product will give the number of seeds in the bushel with sufficient exactness. When this is known, the seeds are to be proportioned by the Rule of Three to the square feet in an acre; or else it may be done, by dividing the seeds of the bushel by the square feet in an acre, and the quotient will give the number of seeds for every foot. Then the farmer is to consider how near he intends to plant the rows, and whether single, double, treble, or quadruple; for the more numerous the rows are, the more seed will be required. The narrow spaces between double, triple, or quadruple rows, suppose seven inches, the double having one, the treble two, and the quadruple three, are called *partitions*. The wide space, suppose of five feet, between any two of these double, treble, or quadruple rows, is called an *interval*.

Examine next what is the produce of one middle sized plant of the annual, but the produce of the best and largest of the perennial sort, because that, by hoeing, will be brought to its utmost perfection; proportion the seed of both to the reasonable product, and when it is worth while adjust the plants to their competent number with the hand-hoe after they are up, and plant perennials generally in single rows. Lastly, plant some rows of the annual thicker than others, which will soon give experience, preferable to all the rules in the world, for the quantity of seed necessary for the drilling.

The distances of the rows is one extremely material point in the obtaining a good crop; but as a much larger distance is to be allowed in these, than common practice has been used to, it is very difficult to persuade the farmer to venture a trial at such distances as he may have experience from. There is a method of planting the rows by the drill at very near distances, and in this work one horse may draw a drill with eleven shares, making the rows at three inches and a half distance from each other, and at the same time *sowing* in them three different sorts of seeds, which do not mix, and these at different depths. Thus the barley-rows may be

be seven inches asunder, and the barley four inches deep; a little more than three inches above that, in the same channels, clover-seed; and betwixt every two of these rows, a row of saint foin seed covered half an inch deep.

Mr. Tull, who tried this method, obtained the first year a very good crop of barley, the next year two crops of broad clover, where that was *sown*; and where hop-clover was *sown*, a mixture of that and of saint foin, and every year afterwards a crop of saint foin. But the same gentleman was afterwards so fully convinced of the folly of these, or any other mixed crops, and of *sowing* with these narrow spaces, that he never practised it afterwards.

Every row of vegetables to be horsehoed, ought to have an empty space, or interval, of thirty inches, on one side of it at least, and of near five feet in all sorts of corn: this will seem a monstrous allowance to those who have not experienced the good effects of it, but all who have will readily come into the practice of it ever afterwards. The line of corn is called one row, though it be double, triple, or quadruple, because when four of these rows grow up in the spring, they unite, and seem to be all one row. Wide intervals are necessary for perfect horsehoeing, and the largest vegetables have generally the greatest benefit by them, though small plants may have considerable benefit from much narrower intervals than those of five feet.

In handhoeing there is always less seed, fewer plants, and a greater crop, *cæteris paribus*, than in the common *sowing*; yet there the rows must be much nearer than in horsehoeing, because as the hand moves many times less earth than the horse, the roots will be sent out in a like smaller proportion; and if the spaces, or intervals, where the broad hoe only scratches a little of the surface, should be wide, they would be so hard and stale underneath, that the roots of perennial plants would be a great while in running through them, and the roots of annual plants would not be able to do it at all. The advantage of the horsehoeing is principally owing to the depth to which it stirs the ground, and familiar instances have proved, that the stirring it to a like depth, by whatever instrument, is of the utmost advantage to whatever plants are set in the place. A poor fellow in Wiltshire was observed to have always his cabbages much larger and finer than his neighbours, though his ground was no better, and he could afford less dung; but the reason was, that instead of clearing away the weeds between them with a handhoe, he used to dig between with a spade, which goes as deep as a horsehoe, and comes the nearest answering its purposes of any instrument whatever. *Tull*'s Horsehoeing Husbandry. See the article INTERVALS.

Man has found out many advantageous ways of propagating, whether by *sowing* or planting such trees and herbs as he best knows the uses of, but nature as much excels him in this article as in all the rest, when any comparison can be made; and it appears evident to the naturalist, that she has taken more care to propagate and *sow* the most trivial weeds, as we esteem them, than we can employ in regard to the choicest plant. It is owing to this care, that no one species of plant has ever been lost, notwithstanding all the accidents they are daily subject to.

There is not, perhaps, a more eminent instance of this care of nature, than in that plant, commonly known in America under the name of the *wild pine*, and called by botanists *viscum caryophylloides*. This is a large plant with leaves like the pine-apple, and it grows on the boughs of other trees, as misletoe does with us, but that its roots do not pierce into the substance of the wood, as is the case in this plant, but only spread themselves upon the surface. The seeds of this plant are small and light, and they have a very long and fine down adhering to them, by means of which, as soon as they are dislodged from the capsules, they are taken up by the winds, and supported in the air till they strike against some branch of a tree which is proper to give them a place of growth: here the downy fibres become of a second use, in that they hold fast the seed, and will not let it drop down, but it remains thus supported till the time of its striking root, which it does from many points at once, and consequently a number of roots are immediately propagated, in different directions, over the surface of the bark. Philos. Transact. N° 251. p. 116.

It is necessary, to the support of this plant, that it should always have a quantity of water within itself to supply its juices. This water is retained in the center of the leaves, which are hollow within, and form a sort of bulb for this purpose; but as it cannot be preserved, unless the plant stands erect, and as the seeds, in their various flight before the wind, are as often struck against the lower, or side parts, as against the upper surface of a bough, so the plant generally begins to shoot in a wrong direction; but so provident is nature, that it immediately turns itself up, whether from the side, or from the very bottom of the branch. This reservatory is not only of use to the plant, but serves also to the birds, and to several small animals, who, in times of scarcity of water, go to it, and seldom fail of finding enough there: nay, Dampier tells us that himself and his sailors, when on shore in some of the American islands, and in distress for water, have been often relieved by it; for that, on striking in a knife a little above the root, the water always came out in large quantities, and they used to catch it in their hats, and drink as much as they had occasion for.

The fastening of the seeds of this plant to the branches of trees, on which they are to grow, is not a single instance of the providence of nature in propagating vegetables: we see in the sea fucuses something of a like kind. The proper place of growth of these is on rocks and stones, and accordingly, as the seeds of the viscum are made light, that they may fly in the air, and ascend to the places where they are to grow, so those of the fucuses are made heavy, that they may descend even in water, and fall upon the stones that are to give them support. This peculiar gravity is given to the seeds of the sea plants, by means of a glutinous jelly with which they are surrounded while in the capsule, and which falls out with them; and is not only of use in carrying them to the bottom, but also in fastening them to the stones on which they alight, otherwise they would easily roll off again, and be tossed about, and lost among this immense bed of waters; but by means of this jelly they are firmly kept in their place, till they have made such shoots as are sufficient to support them against the washing of the waves; then the jelly dries away, and leaves the water free access to them, to nourish them.

The mosses have been by former ages supposed to have no seeds at all; but it has of late been found that they have immense numbers, and those of the only kind that could be of service to their propagation; that is, such as are extremely small and light. It is necessary that the seeds of these minute plants should often be carried upward, in order to their being placed on trees, walls, and other eminences: this is easily performed by the winds, when the seeds are so small, that, on being dislodged, they look like smoak, not like any solid substance; but it could not have been so well executed, had they been larger. The common cup-seeding mushroom produces, on the contrary, large and solid seeds; these cannot grow in any season but a very moist one, and nature providing for this, has so ordained it, that the cup remains closed, and the seeds firm in its bottom, in dry weather; but as soon as a shower of rain falls the cup opens, and the seeds are washed out and thrown upon the wet ground, where they immediately grow. Philos. Trans. N° 251. p. 118.

Many of those plants, whose seeds strike well from the surface, and do not require to be buried as others do, are furnished with a downy substance to every seed, which makes the whole so light, that it floats in the air, and is carried to great distances; by this means every seed is carried a vast distance its own way, and if one falls on an improper soil, another succeeds better. We have a very remarkable late instance of the spreading of plants, from this process of nature, in the small Canada fleabane with toad-flax leaves. This plant was, some years after the settlement of the French in America, brought into Europe, and first *sown* in the gardens of France, and then in those of England; out of both which its downy seeds were wafted by the winds into the fields, and there produced the plant, which thence became a wild inhabitant, both of France and England, and continues so to this day, thriving as well with us as in its native soil.

Other plants, which are destined to grow at some small distances from one another, have been provided by nature with elastic, or springy seed-vessels, which throw their seeds to a distance, without the help of man. The yellow arsmart, and some of the cardamines, called for this reason *noli me tangere*, are of this kind, as also our wild wood-sorrel, and many others. In all these plants, as soon as the seed is perfectly ripe, and fit for *sowing*, the seed-vessel bursts at the first rude shock of wind, and tosses out its seeds to three feet distance in some cases. This distance is also encreased by the action of the wind, which bursts the capsule, and the separated seeds are often carried thus to five, six, or seven feet distance from the mother plant, and scattered different ways, some falling by the way, and the rest spreading abroad as they go along.

There is one remarkable instance of the care of nature of one plant in this way, which is the *spirit weed* of Jamaica. The seeds of this plant can only grow in a wet season; and in consequence of this it is so provided, that the pods containing them can only open in wet weather; they will remain ever so long whole upon the plant in a dry time, but as the first shower falls, the seed-vessels being wetted, burst open, and scatter their seeds several ways, and every one immediately strikes root and grows.

The lychnises, poppies, and snapdragons, all have their seed-vessels open at the top only, and in these the seeds lie securely till a windy season happens, then they are dislodged; and do not fall all together, as they otherwise would, in one spot, raising a cluster of young plants to starve and spoil one another; but they are, according to the same great intent of nature, scattered to such distances, that every one may produce a plant

a plant in fuch circumftances as it may thrive under. Philof. Tranf. N°251. p. 120.

SPA (*Cycl.*)—SPA-*water*. The contents of this *water*, by means of which it is able to do fuch great things in many chronical cafes, are underftood by the following experiments and obfervations.

1. When the *Spa-water* is carried to any diftant place, though ever fo well ftopped down, they always, after a time, will precipitate a fmall quantity of a yellow ochreous earth.

2. If a fingle grain of galls be put into an ounce of *Spa-water*, it tinges the whole with a beautiful purple; but if the *water* be heated before the galls are put in, there will not be the leaft change of colour produced in it.

3. Mixed with milk they do not coagulate it, but when mixed with wine they make a great ebullition, and throw up a large quantity of air-bubbles with a peculiarly pleafing fmell.

4. The *waters* drank at the fpring caufe a fort of drunkennefs, but it does not laft above a quarter of an hour.

5. A fmall vial being filled up to a certain height with *Spa-water*, and afterwards exactly to the fame height with pure diftilled water, and weighed, when filled with each, in a nice balance, was found, when the *Spa-water* was in it, to weigh three ounces, four drachms, and forty grains, and with the other, three ounces, four drachms, and forty one grains; fo that the *Spa-water*, notwithftanding its mineral particles, is fomewhat lighter than the pureft common water.

6. And finally, a pint of the *Spa-water* evaporated over a very gentle fire, leaves behind only a grain and half of a white powder.

Hence it appears, that the *Spa-waters* are the lighteft and moft fubtle of all the mineral waters; and the fmall quantity of earth, and large portion of fubtle mineral fpirit they contain, befpeak their poffeffing the moft exalted virtues of all the mineral waters.

One very remarkable virtue of this *water* is, that it greatly relieves in all diforders of the kidneys, ureters, and bladder, whether occafioned by ftone, gravel, or ulcerations. It poffeffes, befide, all the virtues of the other mineral waters, and is of the greateft fervice in edulcorating fharp, and dividing vifcous humours, and removing all difeafes arifing from thefe caufes, by difpofing them to pafs off by the proper emunctories.

SPADE, (*Cycl.*) is an inftrument for digging up the ground; the handle, or fhaft, is about three feet long; the head of it is all of iron, the upper part being flat, for the workman to fet his foot on to force it into the ground; the length of the head is a foot, or fifteen inches, and the breadth fix or eight.

SPADO, among the Romans, differed from an eunuch only in this, that the latter was deprived both of the penis and teftes, but the *fpado* of the teftes only. *Hofm.* Lex. univ. in voc. See EUNUCH, *Cycl.*

SPAGIRIC *art*, *ars fpagirica*, a name given by authors to that fpecies of chemiftry which works on the metals, and is employed in the fearch of the philofopher's ftone.

SPAGNUOLA, in the Italian mufic, denotes a guitar.

SPANIEL. This fort of dog is of great ufe, but fubject to many diftempers; among thefe the mange is a very frequent one, and is the moft pernicious of all others to his quiet and his beauty, and is very apt, when one dog has it, to fpread to others that come in its way. The beft cure is a decoction of a large quantity of brimftone, with fome common falt and wood-afhes, in water and urine, of each equal quantities; this is to be ufed three or four times a day, wafhing the creature well with it before the fire, or in the warm fun. If this is not ftrong enough, the fame ingredients, with the addition of a confiderable quantity of wood-foot, are to be boiled in ftrong vinegar, and the liquor ufed in the fame manner; but this muft never be ufed in cold weather, as it would then endanger the creature's life.

When this difeafe is not in a violent degree, it may be cured by the herb agrimony internally taken. The method is to pound the roots, leaves, and feeds of this plant in a mortar, and mix them with a large quantity of wheaten-bran; they are to be then made into dough in the common way, and baked in an oven; the dog is to have no other bread but this for fome time, but he is to eat of this as often, and as much as he will: this, without any farther care, has cured many.

Another very troublefome diforder in this creature, is what is called the *formica:* this infefts only the ears, and is caufed by flies, and by the dog's fcratching for them. The beft medicine for the cure of thefe is this: take a quantity of pure and clean gum tragacanth, infufe it in white-wine vinegar; let as much vinegar be ufed as will ferve to foften it, and when it has lain a week in it, let it be taken out and ground on a marble, as the painters grind their colours, adding to it roach-alum and galls, reduced to powder, of each two ounces; all this is to be well mixed together, and the matter, if it grows too ftiff in the grinding, is to be moiftened with fome of the vinegar in which the gum was foaked: when all is thoroughly mixed, and ground fine, it is to be put by in a gallypot, and a fmall quantity of it applied to the creature's ear every night till the complaint is removed.

The fwelling of the throat is another difeafe very common to *fpaniels*, but the cure of this is eafy, there needs only to bath it well with oil of camomile, and afterwards wafh it with a mixture of vinegar and falt; this done night and morning will, in a few days, wholly remove the complaint. *Spaniels* will fometimes, when they have much reft and good food, lofe their fenfe of fmelling, but this is recovered by a brifk purge and repeated airings; a very common dofe, on this occafion, is a drachm of jalap, and two drachms of fal gem, mixed up into a bolus with oxymel of fquills: this is to be rubbed over with fome butter, and will be got down in that manner pretty eafily, and will work brifkly.

SPAR, (*Cycl.*) in natural hiftory. *Spars* are defined to be foffils not inflammable, nor foluble in water. When pure, pellucid and colourlefs, and emulating the appearance of cryftal, but wanting its diftinguifhing characters; compofed of plane and equable plates, not flexile nor elaftic; not giving fire with fteel; readily calcining in a fmall fire, and fermenting violently with acids, and wholly foluble in them.

Of this clafs of bodies there are ten orders, and under thofe twenty one genera, many of which, from their accidental admixtures, deviate greatly in appearance from the natural ftate of pure *fpar*.

Of the firft order are the pellucid cryftalliform and perfect *fpars*, compofed of a column terminated at each end by a pyramid.

Of the fecond are thofe compofed of two pyramids joined bafe to bafe, without any intermediate column.

Of the third are the cryftalliform columnar *fpars*, adhering by one end to fome folid body, and terminated at the other by a pyramid.

Of the fourth are the pyramidal cryftalliform *fpars* without columns.

Of the fifth are the *fpars* of a parallellopiped form.

Of the fixth are the *fpars* externally of no regular form, but breaking into rhomboidal maffes.

Of the feventh order are the cruftaceous *fpars*. Thefe are of a cryftallino-terrene ftructure, or debafed from their native pellucidity by an admixture of earth, and formed into plates or crufts of a ftriated figure within.

The eighth order comprehends the cruftaceous terrene *fpars*; bodies fo highly debafed with earth, as to appear merely earthy, of an irregular ftructure, and not ftriated within. Thefe often encruft fiffures of ftone, and fometimes vegetable and other extraneous bodies in fprings.

Of the ninth order are the *fpars* formed into oblong cylindric bodies, known by the name of *ftalactitæ*, or ftony icicles.

And the tenth comprehends thofe formed into fmall round figures, compofed of various crufts enclofing one another, and generally known by the name *ftalagmitæ*; and adding to thefe the *fpars*, influenced in their figures by metalline particles, we have the whole feries of thefe bodies. Thefe are, 1. the *cubic*, owing their figure to lead. 2. The *pyramidal* with four planes, owing their figure to tin. 3. The *rhomboidal*, confifting of fix planes, owing their figure to iron. *Hill*'s Hift. of Foffils, p. 201.

The genera of thefe feveral orders are thefe.

Of the firft there are three. 1. The *triexahedria*, thofe which are compofed of a hexangular column, terminated at each end by a hexangular pyramid. 2. The *tripentahedria*, thofe compofed of a pentangular column, terminated at each end by a pentangular pyramid. And 3. the *enneahedria*, which are compofed of a trigonal column, terminated at each end by a trigonal pyramid.

Of the fecond order there are three genera. 1. The *dioctahedria*, *fpars* compofed of two octangular pyramids joined bafe to bafe. 2. The *diexahedria*, compofed of two hexangular pyramids joined bafe to bafe. And 3. the *ditrihedria*, which are compofed of two trigonal pyramids joined bafe to bafe.

Of the third order there are alfo three genera. 1. The *hexaedroftyla*, which are hexangular columns, terminated by hexangular pyramids. 2. The *pentaedroftyla*, compofed of a pentangular column, terminated by a pentangular pyramid. And 3. the *triedroftyla*, compofed of a trigonal column, terminated by a trigonal pyramid.

Of the fourth order there are only two genera. 1. The *hexapyramides*, *fpars* in form of hexangular pyramids without columns. And 2. *tripyramides*, thofe in form of trigonal pyramids without columns.

Of the fifth order there is only one known genus, the *parallelopipedia*, *fpars* of a regular parallellopiped figure, as well in their whole maffes, as in their conftituent particles.

Of the fixth order there is alfo only one known genus, the *anomorhomboidia*, *fpars* of no regular external figures, but breaking into rhomboidal maffes.

Of the feventh order there are two known genera. 1. The *placagnodiaugia*, femipellucid, and of a ftriated texture within, and

and of cruftaceous external figures. And 2. the *placagnofcuria*, opake cruftaceous *fpars* of an irregular ftructure within.

Of the eighth order there are two genera. 1. The *cibdeloftracia*, terrene *fpars*, found in form of thin plates on the furfaces of fiffures in ftone quarries. And 2. *cibdeloplacia*, terrene *fpars*, ufually found coating over vegetable, or other extraneous matter in fprings, &c.

Of the ninth order there are two genera. 1. The *ftalactagnia*, cryftalline *fparry* ftalactitæ. And 2. *ftalacto-cibdela*, cryftallino-terrene, *fparry* ftalactitæ.

And of the tenth order there are alfo two genera. 1. The *ftalagmodiaugia*, or pellucid *fparry* ftalagmitæ. 2. *Stalagmofcieria*, dull and opake *fparry* ftalagmitæ. *Hill's* Hift. of Foffils, p. 203.

The obfervation that *fpar* is continually formed at this time in caves and grottos under ground, has given birth to many different conjectures as to the origin of that fubftance. We have accounts from Swifferland, and other places, that the fnow by long lying on the earth, and being fubject to repeated freezing, is at length hardened into *fpar*: this is much of the nature of that opinion of the antients concerning cryftal, that it was water frozen by fevere colds to a fort of ice, much harder than the common kind; both are equally erroneous and abfurd. But more rational conjectures, as to its origin, are, that it is produced either by effluvia alone, or by the joint force of effluvia iffuing up from the depths of the earth, and mixing with water ouzing out of rocks into their cracks and cavities, or by the fame water or effluvia paffing through beds of this *fparry* matter contained in clay. In the firft place we are to obferve, that *fpar* is capable of being diffolved either by water or vapour, and fufpended imperceptibly in either; and that though it remains fufpended a long time, yet there are occafions of its feparating itfelf from either of thefe vehicles, fuch are long ftanding ftill, and evaporation. What is called the growth and formation of *fpar*, therefore, is properly perhaps only the change of place in this fubftance, and all that thefe agents, water and vapours, do, is only to wafh it out of the ftrata of earth or ftone, in which it lay in fcattered particles, and bring it together into the cracks and crevices of ftones, where it may again feparate itfelf, and become more pure and perfect. The operation of nature, in this cafe, is very like that of art in the extracting of falts from the various bodies they are mixed with; and *fpar* in its two ftates, when blended in the ftrata of ftone, &c. and when pure, and in form of cryftals in the cracks, may be compared to alum, for inftance, in its bed, and when purified. The alum in the common ftones, from which it is made, is not perceptible to the eye, but lies in fcattered particles; water being added to this takes up the falt, and when it has been managed by evaporation and reft, yields it again purified and alone, and it forms fuch cryftals on the fides of the veffel as the other does on the fides of the fiffures of ftone, which are the veffels where the water, out of which it was formed, was fet to evaporate, and to reft a proper time. That fome *fpars* grow from vapours alone, is evident from the *ftalactitæ*, or ftony icicles, hanging down from the roofs of our caverns, which, though they grow downwards, yet have many times little plants of the fame fubftance growing out at their fides, and ftanding upwards, contrary to the growth of the other, and evidently formed of the matter feparated from the vapours in their afcent, as the ftalactitæ themfelves are from fuch as have afcended to the roof, and there been condenfed into water, and fent down again in drops. Nor is the *fparry* matter alone thus raifed in vapour, for even the metals, and other bodies, as little likely as thofe to be thus raifed, yet are found to form ftalactitæ. The mundics in general, though they never form regular ftalactitæ, yet often are found adhering to the fides of them, and the metals, particularly iron and lead, form regular ftalactitæ; the iron ones very common, and very perfect; the lead lefs perfect, and more rare; and Dr. Brown gives us abundant inftances, of *fpars* growing entirely from vapours in the baths of Buda in Hungary. Phil. Tranf. N° 129.

Mr. Beaumont [b] is of opinion, that earth by degrees will ripen into *fpar*; but this is an error. He founds his opinion on certain ftalactitæ, and ftalagmitæ, found in caverns, partly earth and partly *fpar*, and fuppofes, that the whole would in time become *fpar*; but there is nothing in nature to warrant this conjecture.—[b Phil. Tranf. ibid.]

Mr. de Juffieu has given us, in the Memoirs of the Paris Academy, a very remarkable account of the recryftallization, or reproduction of the parts of *fpar*, after folution, in the following inftance.

There are found in the mines near St. Bell, where they dig copper-ore, a fort of ftones, which ufually cover the vein of the ore; thefe are compofed of feveral flat plates laid evenly on one another, as our rhomboidal and parallellopiped *fpars*, and thefe, as the diftinctions of foffils were not at that time eftablifhed, the author called, from their eafy calcination, a fort of gypfum, which he diftinguifhed from the reft by their plated ftructure. They are white on their outfide, and greyifh within; and their internal part being heavy, and full of fparkling points, they were fuppofed to contain fome copper, and were thrown into the furnace ufed for roafting the other ftones in which copper was lodged. The calcination reduced thefe ftones into a fort of plafter, or gypfum. After this thefe calcined ftones, which were now as red as colcothar of vitriol, were thrown into tubs, and large quantities of water were poured on them; this took up their cupreous, their vitriolic, and their *fparry* particles. From thefe tubs the impregnated liquor was let out into a bafon, in the midft of which were placed feveral pieces of iron; thefe were all immediately changed in appearance into copper by the liquor. The liquor fent up all this while a thick white vapour, which covered all its furface, and arofe to the height of a foot above the edge of the bafon. This vapour by degrees diffipated itfelf into air; but where it had touched, not only the fides of the bafon that were above the furface of the liquor, but alfo the earth about the edges, were covered with fmall regular cryftals, of a figure approaching to a parallellopiped, and of an infipid tafte, in fome degree tranfparent, and very thin and flat in proportion to their breadth or length. Thefe were the fingle cryftals, but the continual formation of them, one upon another, at length formed of them concrete maffes, refembling large cakes of tartar. Thefe were like the other a true *fpar*, being indiffoluble in water, and eafily calcining in the fire, and having all the other qualities of the ftones from which they were originally obtained. This procefs is the more fingular, as calcination is a very ftrange method of procuring the cryftals of a body, and in this fubftance feems entirely to deftroy them in their original ftate; fo that chance alone could have difcovered a property of their rifing in vapour from this, and again affuming their proper form; but it would deferve a trial whether the common *fpars*, which will recryftallize after folution in the acid menftrua, will alfo do it after calcination. Mem. Acad. Par. 1719.

SPARS, in medicine, have from the earlieft times been recommended in nephritic complaints. Some have ufed one kind, fome another, as the *lapis judaicus*, the *fparry* incruftations of caverns, petrified oyfter-fhells, and water in which large quantities of *fpar* are fuftained. After all, the nephritic virtues of *fpar* want fufficient proof; fome even fufpect its ufe to be more hurtful than beneficial. See CRYSTAL.

It were to be wifhed, that whoever attempts to afcertain this point, would choofe for the experiment fome determinate kind of *fpar* in its natural form, rather than under appearances, whereby its efficacy may be confounded with that of other bodies. See the articles BELEMNITES and OSTRACITES.

SPARAGUS, or ASPARAGUS, *fperage*, in botany. See the articles ASPARAGUS and SPERAGE.

SPARGANOSIS, a word ufed by fome to exprefs a milk-tumor in women's breafts.

SPARGUS, in ichthyology, a name given by Gaza to the common fparus, which he calls alfo *fluta*.

Artedi calls it the plain yellow *fparus* with an annular fpot near the tail. See SPARUS.

SPARLING-*fowl*, in zoology, a name given in fome places by the country people to the female merganfer, called more ufually the *dundiver*. This fo much differs from the male of the fame fpecies, as to have deceived the generality of authors into thinking it a different bird.

SPARRING, or SPARING, among cock-fighters, a term ufed to fignify the fighting of a cock with another to breathe him; in which fights they put hotts on their fpurs, that they may not hurt one another. Sportfm. Dict. in voc. See the article HOTTS.

SPARROW, in zoology. See the article PASSER.

SPARROW-*grafs*, in botany, &c. See ASPARAGUS.

SPARSE-*leaves*, *fparfa folia*, among botanifts. See LEAF.

SPARTIUM, in botany, the name of a genus of plants, the characters of which are thefe. The flower is of the papilionaceous kind; the piftil, which arifes from the cup, finally becomes a fhort roundifh turgid pod, which ufually contains a kidney-fhaped feed.

The fpecies of *fpartium*, enumerated by Mr. Tournefort, are thefe. 1. The yellow-flowered *fpartium* with a kidney-fhaped feed. 2. The white-flowered Spanifh *fpartium*. 3. The prickly ebony-like purfelain-leaved American *fpartium*. And 4. the climbing citron-leaved American *fpartium* with white flowers growing in clufters at the joints. *Tourn.* Inft. p. 645.

SPARTOPOLIAS *lapis*, in natural hiftory, a name given by fome authors to a whitifh agate, variegated with long and flender ftreaks of grey difpofed in a varioufly undulated order, and refembling grey hairs.

SPARUS, in the Linnæan fyftem of zoology, the name of a genus of fifhes of the general order of the acanthopterygii, the characters of which are, that the opercula of the gills are fcaly, and the mouth is furnifhed with grinders covered with lips. Of this genus are the fargus, cantharus, melanurus, &c. *Linnæi* Syft. Nat. p. 54.

In the Artedian fyftem of ichthyology, the characters of this genus of fifhes are thefe. The coverings of the gills are fcaly. The teeth are covered with lips, as in quadrupeds. The

The teeth in the jaws resemble the dentes canini of men. The molares, or grinders, are like those of quadrupeds. The teeth are placed only in the jaws and fauces, their palate and tongue being smooth. There is but one back fin. The eyes are covered with a lax skin, and the tail in most of the species is forked. The intestines are long, and they are twisted in spiral forms, and often fixed to the mesentery. The appendices to the pylorus are large, and few in number, from three to seven being the usual numbers.

Of the *spari* some have acute and cylindric teeth; of these the following are the species of them. 1. The *sparus* with a very acute back, and an arched yellow spire between the eyes. This is the *aurata*, or gilt-head. 2. The silver-eyed *sparus* with yellow parallel longitudinal lines on each side. 3. The red *sparus* with silver eyes. This is the *rubellio* of authors. 4. The reddish *sparus* with the skin formed into a sinus at the root of the back fin and the pinna ani. This is called the *brama marina*, or sea-bream. The tail is forked, and the mouth has granulous tubercles in it. 5. The variegated *sparus* with an acute back, and with four large teeth. This is the *dentex* and *synodon* of authors. 6. The *sparus* with four longitudinal parallel lines, of a golden and silvery colour. This is the *boops* of authors. 7. The variegated *sparus* with a black spot in the middle of each side, and with four large teeth. This is the *mana* of authors. 8. The *sparus* with a black spot on each side, and with the pectoral fins and the tail red. 9. The *sparus* with the upper jaw longest, and with two transverse black lines on each side. 10. The *sparus* with the second bone of the belly fins extended into a long hair. This is the *chromis* of authors. 11. The variegated *sparus* with an equal tail, and a black spot in it near the end. This is the *orphus* of authors. Its head is reddish. 12. The yellowish *sparus* with a single annular spot in the tail. This is the *sparus* of authors, Artedi only having used the name in this extensive generical sense. 13. The *sparus* variegated with yellow transverse lines, with a large and remarkable spot at the tail. This is the *sargus* of authors. 14. The *sparus* variegated with longitudinal lines, with a black spot on each side of the tail. This is the *melanurus* of authors. 15. The *sparus* with eleven lines on each side, which are gold coloured, and run longitudinally and parallel to one another. This is the *salpa* of authors. Thus have the several fishes, which are only so many species of the same natural genus, been treated of under almost as many generical names, to the great confusion of those who apply to this study. *Artedi*, Gen. Pisc. p. 28.

The *sparus* is common in the Adriatic, and some other seas, and esteemed a very delicate fish. *Aldrovand.* de Pisc. lib. 2. cap. 18. *Gesner*, Paralip. p. 1056.

The name *sparus* is of Greek origin, being derived from the verb σπαιρειν, to palpitate, or tremble; and was given to this fish from its remarkable quality of trembling or palpitating all over the body, as soon as taken out of the water.

SPARUS, among the Romans, a kind of rustic weapon, bent backwards like the foot. It was likewise used for a small dart, or missive weapon. *Pitisc.* in voc.

SPASM (*Cycl.*)—A *spasm* may be either universal, extending itself over the whole body, which is a very rare case; or partial, occupying only some one part of the body: these are very frequent, and seize at times on every part, from the head to the foot.

Of the nature of the universal *spasms* are, 1. the *tetanus*, which seizes upon the whole body, and makes it stiff and rigid in every part. 2. The *emprosthotonos*, which bends the body forwards, so that the head is brought to meet the knees. 3. The *opisthotonos*; this enclines the whole body forcibly backwards. And 4. the *catalepsis*, which seizes the whole system in a moment, and fixes it rigidly and unalterably in that posture in which it finds it; so that the position of every limb, and the very turn of the countenance, and look of the eyes, is the same as when the patient was seized. This is a very rare case.

To the class of particular and partial *spasms* belong 1. many of the arthritic complaints. 2. The *incubus*, or nightmare, which is a *spasm* of the breast. 3. The *convulsive asthma*. 4. The *cynic spasm*, which is a peculiar distortion of the face, resembling that of a person while laughing. This endures usually many hours, and is often of very fatal consequence, frequently terminating in an apoplexy, or in the most terrible convulsions. 5. The *sardonic laugh*, which only differs from the former in that it is attended with an absolute delirium, which is not the case in the other. 6. The *priapism*, which is an involuntary and painful erection of the penis. 7. The spastic contraction of the colon in flatulent colics. 8. The *fixt spasms* of Paracelsus, which the author describes as often afflicting podagric and arthritic patients. *Junker's* Consp. Med. p. 608.

Spasms in general, beside these distinctions, are divided by authors into the sudden, or instantaneous, which seize upon any muscle in a moment, and keep it for a considerable time in a painful state of contraction, and the slow ones. The *slow spasms* are also divided into two kinds. 1. The *muscular* and *tendinous*. And 2. the *fibrillary*. In the first of these the whole muscle is affected with tensive pains, and the limb becomes finally contracted. In the other, the separate fibres in the muscle are only affected. This is usually the case in *spasms* in arthritic cases, which seize a few fibres only at first, but finally fasten upon more, and extend themselves over the whole muscle, in which case the pain usually becomes less. A tensive pain in the neck, occasioned by sitting or lying in an uneasy posture, usually called a *crick in the neck*, is also to be enumerated among the partial *spasms*; and finally, these affections are not restrained wholly to the external parts, but often seize also upon the internal, as the œsophagus, the stomach, the bladder, &c.

It is a common error to confound the word *spasm* with *convulsion*; their difference is evident, the one being stationary and immoveable, the other erratic, and flying from one part of a muscle to another, and from one muscle to another; the convulsion also usually extends itself farther than the *spasm*, and is greater in degree; and finally, the *spasm* is a much less dangerous complaint than the convulsion. Men are more subject to *spasms* in general than women, and among them, such as are of a sanguine and plethoric habit, are most of all subject to them. The general cause of *spasms* is an abundance of blood in a body where the vessels are small, and nature is endeavouring to throw off the load of the plethora from vessels, where it is troublesome to her, by this means; which, though an erroneous one, is therefore not without its end.

Prognostics in SPASMS. The universal *spasms* are greatly the most dangerous, as they are frequently attended with internal inflammations; and the partial *spasms* too often degenerate into convulsions. If *spasms* are very frequent in young people, they are to be suspected of threatening arthritic complaints in old age; and when persons have been free from *spasms* in their youth, and become subject to them when old, it is much to be feared that they portend apoplexies, palsies, and suffocative catarrhs: and in general all *spasms*, as they are in reality no other than the incomplete attempts of nature to free herself of somewhat that offends her in particular parts, portend some worse mischief, when they are observed to return frequently, and with violence. *Spasms* happening in acute diseases, and from wounds, are all very dangerous symptoms, and threaten convulsions, and other mischiefs.

Method of cure. The means to be used, when the fits are off, are bleeding in any manner, by the lancet, by leeches, or by cupping, as may be most proper in regard to the part principally affected, and other circumstances; after this the primæ viæ are to be cleared by purges from any foulnesses that may adhere to them; and finally, such medicines are to be given, as are known to attenuate the blood; and with all this, gentle exercise is of great service. In the time of the fit, lenient and paregoric medicines of this kind are amber, and the spirit of hartshorn: to these are to be added the acrid vegetables, such as the more temperate carminatives, and the emulsive diluent medicines, with nitre and cinnabar. This last drug is famous alone in all these cases, and indeed in all emotions of the blood; but neither this, nor any of the others, will take effect till after bleeding, if the *spasm* be violent. The volatile alkalis also succeed best when mixed with a fixed one; such as the spirit of hartshorn with the tincture of salt of tartar, or of antimony. *Junker's* Consp. Med. p. 612. See CONVULSION, *Appendix*.

SPATAGOIDES, in natural history, the name of a genus of the *echini marini*, the characters of which are; that it has the aperture for the anus on one side of the upper surface, and has a large furrow on the back, which makes it of a cordated form; but has no furrows on the vertex, but only four or five smooth rays, made of a number of slight transverse striæ. See Tab. of Testaceous Animals, N° 14.

SPATANGI, in natural history, the name of a genus of the *echini marini*, including all those which are marked in the shape of a heart, and have the aperture for the anus in one of the sides of the upper superficies. These have all a remarkable furrow on the back; their base is nearly flat, and they have several furrows on the vertex. By these characters they are distinguished from the brissi, with which they have in common the marks of two lips to their mouth, and want the teeth the other kinds have. See Tab. of Testaceous Animals, N° 11. *Klein's* Echin. p. 35.

SPATHA, is a word used by different authors in various senses; some express by it a rib; others the instrument called by surgeons a *spatula*, and used for spreading ointments and plasters; and Celsus calls a sort of incision-knife by this name. It is also used for the external covering of the fruit of the palm-tree, and by others for a sword. This last is indeed its proper signification, and all the others are only metaphorical applications of it to different things, which bear some resemblance to a sword.

SPATHA, among botanists, expresses that sort of cup which consists of a simple membrane growing from the stalk. This kind of cup is of various figures; often diphyllous, or divided into two parts; often simple; sometimes more divided: it incloses sometimes a single flower, sometimes several flowers

flowers together, and these have often no perianthium. The *spatha* is of very different texture, and consistence, in different plants.

SPATHA, among the Romans, is sometimes taken for a broad sword, sometimes for a sort of ladle used by cooks, and also for a surgeon's instrument. *Pitisc.* in voc.

SPATHALIUM, among the Romans, an ornament which the women wore about their hands, not unlike the coral ones of the moderns. *Pitisc.* in voc.

SPATHESTER, the name of a chirurgical instrument used to draw the prepuce over the glands.

SPATHINUS, in natural history, a name given by the Greeks to the stag, or deer, when in its second year.

In the first it was called *nebrus*; in the third year *dicrotus*; and after this *cerastes* as long as it lived.

SPATHOMELE, a word used by some to express the spatula, and by apothecaries and surgeons in mixing and spreading ointments and plasters.

SPATLING-*poppy*, a name given to the common field-lychnis, from the white froth found on it in the spring. See the article FROTH-*spit*.

SPATULA, (*Cycl.*)—The use of the *spatula* is to depress the tongue, in order to examine the state of the tonsils, uvula, and fauces, when they are affected with any disorders. It is also used to suspend the tongue, when the frænum is to be divided; for which purpose it has a fissure at its extremity, and should rather be made of silver than of any other metal. These *spatulæ* are made of different shapes. Vid. *Heister's* Surg. Introd. sect. 36. and Plate I. P. Q. R.

SPAX, a name given by some authors to the common tænia, a small fish of the anguilliform-kind, frequent on the shores of Italy. *Rondelet.* de Pisc. p. 112.

SPEAR, in the manege. The feather of a horse, called the *stroke of the spear*, is a mark in the neck, or near the shoulder of some Barbs, and some Turky and Spanish horses, representing the blow or cut of a *spear* in those places, with some resemblance of a scar. This feather is an infallible sign of a good horse.

SPEAR-*hand*, or *sword-hand* of a horseman, is his right hand.

SPEAR-*foot*, of a horse, is the far-foot behind. See the article FAR, *Appendix*.

SPEARWORT, the English name of the *ranunculus flammeus*. See the article RANUNCULUS.

This is with us generally esteemed a poison, but the Scotch use it as a medicine. They beat it, and squeeze out the juice, which they take as a purge, drinking a little melted butter or oil before and after it, to prevent its taking the skin off from the throat. It operates very violently, but with their robust constitutions it does very well.

They use it also externally in cases of pain in the head, or any other part of the body. They bruise the leaves to a sort of paste, and apply them to the part; they soon raise a blister, and a large quantity of water is discharged, after which the pain goes off. This is a short way of blistering, and answers as safely, and as well as ours by the cantharides: but it is a wonder that people, who see this quality in the plant, should dare to take it into their mouths and stomachs.

SPECIES (*Cycl.*)—It has been generally allowed to be true, that no *species* of animal, once created, ever became extinct, or ever will be: but though this may be true in general, yet it does not follow, but that a whole species of animals may be extinct in some particular place by various accidents.

This seems to have been the case with the great moose-deer, now found only in America, which was certainly once an inhabitant of Ireland, though now extinct there, and that so long ago, that no historian mentions its ever having lived there.

There are many animals, as well as trees and plants, common to America and to Ireland. The horns of the moose-deer are found with the bones of the head, and sometimes with other bones, in immense quantities, to this day, in that kingdom, buried in strata of marl at great depths. The writers of fossils, who are fond of resolving every thing into the effects of the deluge, affirm, that these horns were brought from some other country by the waters of the flood; but they seem to be as improbable things to be brought by the sea, and left uninjured in other countries, as can well be conceived; and they are too little altered, and too well preserved, to suffer an unprejudiced observer to agree to this account.

We find numerous instances of the surface of the earth altering, in length of time, in many parts of this kingdom; and it is no forced judgment to determine, that the soil, in which these horns are now found buried, was once the surface of the country, though other substances have been since piled upon it, and made a surface over it. The creatures, whose horns we find buried, probably lived on the island when this was the surface; and as they live in herds, so dying in herds, or at least several together, their bodies were left in heaps upon the surface, where they were afterwards consumed and wasted, only the tough substance of the horns preserving them, they have remained, and being covered with the superadded strata, are now found in this fossile state. In countenance of this opinion it is to be observed, that the deer-kind in general are subject to contagious diseases, which often carry off great numbers of them. The rein-deer in Lapland are sometimes almost all destroyed by these diseases; and it is not impossible that such a distemper, raging longer and more violently than ordinary, might destroy the whole *species* in this place. The inhabitants might also promote the destruction by their hunting; for we see by the destruction of the wolves, once so frequent in this kingdom, that this cause alone may be sufficient to extirpate, or extinguish the race of an animal in one kingdom: Phil. Tranf. Nº 27. p. 501.

What the accurate Artedi has given, as the definition of the *species* in ichthyology, is not confined to fishes alone, but, with proper regulations, may be made the basis of real distinctions of *species* in all other natural bodies. Every fish, which differs from all the other fishes of the same genus in some external part, whether that difference be in excess or defect, in number or in proportion, or even in colour, provided that the difference be fixed and invariable, is properly to be called a distinct *species*. *Artedi's* Ichthyolog.

The specific differences of fishes are to be drawn from these circumstances; but it is not to be supposed that every *species* differs in all of them, sometimes only one, sometimes more, occasion the variation. See SPECIFIC *names*.

If any one fish, in regard to all the others of the same genus, is found to be possessed of some external part which they all want; as for example, if it have cirri, tubercles in the shape of horns on the head, spines or prickles in the head, or on any other part of the body, the fish is then to be esteemed a distinct *species*. If one fish differs from the others of the same genus in the number of any parts, as fins, spines, or tubercles, it is then also a distinct *species*. If one fish differs from another in the proportion of any essential part, as in the having longer jaws, longer teeth, or the like, it is also to be esteemed a truly different *species*. If one fish differs from another in the figure of some essential part, as of the snout, the back, the teeth, or the tail, or the lineæ laterales, it is to be esteemed a distinct *species*. If one fish differs from another of the same genus in the excess of parts, having some part that is deficient in the other; or if in the number, proportion, or figure of some of the essential parts; the distinction will be the more evident as the greater number of parts differ, and the *species* will easily be found to be truly distinct. *Artedi's* Ichthyolog.

If a fish differs from all the others of the same genus in colour, while it has no other distinction from some of them, then it is to be examined whether the colour is always permanent and invariable; if not, there is no distinction of *species* to be founded upon it; but if it be, it remains a matter of doubt whether it may be esteemed a specific difference, colour being one of the least essential characters, and, according to Linnæus, what no distinction of *species* can be founded on. As the colour of fishes is very apt to vary, even in the same *species*, and to be sometimes more intense, sometimes more remiss, this is to be considered in a due light, before any judgment is formed on it; and it is to be observed whether the colour, that makes the difference, be wholly of another nature, or only different in degree. The *perca fluviatilis* of Bellonius will be sometimes pale yellow, sometimes deeper, and sometimes even black, according as the water is clear or more muddy; and thus whatever differences are only in degree of the same colour, or in the changes from that degree toward black, without the intermixture of any other colour, are not to be at all depended upon. *Linnæi* Fund. Bot. 27.

We are not to expect the same precision in the differences of the truly distinct *species* of all the genera of fishes: in some they are found so obvious, and so great, that the first look distinguishes them; but there are some other genera, in which the several *species* are so alike one to the other, in the essential characters, that though there is a general external face, in which they all vary, yet it is not easy to say in what the distinction between *species* and *species* consists. Thus, among the several *species* of salmons, the number and figure of the essential parts is the same in all, and their proportion, in regard to the bulk of the fish, differs but little; the jaws are in some indeed wider, and in others longer, but it is not much. The colours and spots vary indeed greatly, in the different *species*, but then it must be allowed, that they also differ in the several individuals of the same *species*: so that, upon the whole, there is no genus of fish, in which the *species* are so difficultly distinguished. The very bones of the fins, which differ in the several *species* of the same genus, in almost all other fishes, are the same in these. The number of the vertebræ is almost the only mark in which the real difference of these consists: this is a troublesome thing to count, but in the boiled fish it is best done, and is always certain, the number being the same in all of the same *species*, of whatever size, and the several *species* all differing as to this number. Great care is to be taken in the counting of these, and by that means the smallest fish and the largest will be found to have the same number, if of the

fame *fpecies*. There are fome few inftances of the different *fpecies* of the fame genus having the fame number of vertebræ, but this is very rare. Artedi tells us that he never obferved it but in a few of the cyprini; and thofe which have no diftinction in this character, he obferves, have fuch very remarkable external differences, that it is not needful to look for others.

Species *aromaticæ*, a new name given in the late London Difpenfatory to the compofition ufually called *fpecies diambræ*. The College obferved, that the intention of this medicine was beft anfwered, by compofing it of fuch fpices as the daily experience of the table fhews were moft grateful to the ftomach, and by avoiding all ingredients which, though of the aromatic kind, are accompanied with any thing naufeous and difguftful in their flavour; and therefore have ordered it to be now made in the following manner. Take cinnamon two ounces, cardamom feeds, ginger, and long pepper, of each an ounce; make all together into a fine powder. *Pemberton's* Lond. Difp. p. 318.

Species *e fcordio*, the ingredients of the diafcordium electuary in a dry form. The recipe is fumething altered in the late London Pharmacopœia, and ftands thus: take bole armenic four ounces, fcordium two ounces, cinnamon an ounce and half, ftorax, roots of tormentil, biftort, gentian, dittany of Crete, galbanum, and gum arabic and red rofes each an ounce, long pepper and ginger each half an ounce, opium three drachms; this may be left out at pleafure; and all are to be beat to a fine powder. *Pemberton's* Lond. Difp. p. 319.

Species, in mufic. Here, as in other arts, *fpecies* denotes the fubdivifions of the genus. The antients had three genera, the *enharmonic*, *chromatic*, and *diatonic*. The *enharmonic* had no fubordinate *fpecies*. The *chromatic* genus was divided into three *fpecies*, viz. the *molle*, *fefquialterum*, and *toniæum*; or, as others call them, *molle*, *hemiolium*, and *tonicum* [c]. And laftly, the *diatonic* genus was fubdivided into the *molle*, and the *intenfum*; fo that the antients had fix *fpecies*, or divifions of the fourth in ufe. Some of thefe are alfo in ufe among the moderns, but others are unknown, as yet, in theory or practice [d].—[[c] *Wallis's* Append. Ptolem. Harm. p. 164. [d] Vid. Phil. Tranf. N° 481. p. 271, feq.] See the articles Enharmonic, Chromatic, and Diatonic. See alfo Genus.

Species is alfo applied, in antient muficians, to the different difpofitions of the tones and femitones in a fourth, fifth, or octave. Hence they fay there are three fpecies of fourths, four of fifths, feven of octaves. *Wallis's* Append. Ptolem. Harm. p. 171.

The Grecians expreffed this fenfe of the term *fpecies* by εἶδος, or by σχῆμα [e]. The Latin word, *figura* [f], has alfo been taken in the fame fenfe.—[[e] *Ariftox.* p. 6, 74: Ed. Meib. [f] *Wallis*, ibid. p. 170.]

Change of Species. The *change of fpecies* is a term ufed in hufbandry to exprefs an expedient the farmer often has recourfe to, in order to procure good crops: this is the fowing firft one kind of plant, then another, and then a third, and fo on, upon the fame land: by this means the moft is made of the foil; and it is found, when it will no longer give a good crop of the firft corn planted on it, it will ftill give a good one of fome other *fpecies*; and finally, of peafe after all. After this laft *change of fpecies*, it is found neceffary, in the common method of hufbandry, to renew the land with fallowing and manure, in order to its producing any thing again. See Soil.

This *change of fpecies* has been a practice of the farmers of all times, and is recommended, and judged neceffary, by moft of the writers on this fubject; but Tull, in his New Syftem of Horfehoeing Hufbandry, proves, that it is not neceffary, and that the land only wants proper tillage, when exhaufted by one fort of corn, to enable it to produce as good crops of the fame corn again. The three fundamental propofitions he lays down to prove this, are, 1. That plants of the moft different nature feed on the fame forts of food. 2. That there is no plant but what muft rob every other plant, within its reach, of a part of its nourifhment. And 3. that a foil, which is once proper for any kind of vegetable, will continue to be always proper for it, in refpect to the fort of food it gives. If only any one of thefe propofitions were true, it would follow, that there is no need of a *change of fpecies* from year to year; and as they are all fo, this truth is yet the more inconteftible, and experience proves it yet more evidently, for the fame land will produce crops of wheat every year, without any change, only by the practice of the horfehoeing hufbandry, inftead of the common. *Tull's* Hufbandry. See the articles Food *of plants* and Husbandry.

SPECIFIC (*Cycl.*)—Specific *operation of medicines*. Dr. Martin endeavours to defend the doctrine of the *fpecific operations* of cathartic medicines, from the different nature of the drugs, and by an appeal to experience. See his Eff. Phyf. and Medic.

Specific *gravity of metals*. See Metals.

Specific *names*, in natural hiftory, are thofe epithets compofed each of one or more terms, and placed after the generical name, in the denomination of any fpecies of plant, animal, or mineral, expreffing thofe characters by which it differs from all the other fpecies of that genus.

The more accurate of the modern naturalifts have, in their feveral provinces, fet about the reformation of the *fpecific* names of things. They firft obferve, that many of the *fpecific* names of the antients no way anfwered the intent of their formation, but expreffed the more trivial diftinctions, or accidents, while they omitted the realities, and more effential grounds of diftinction. On this foundation the critical writers of our times diftinguifh the old *fpecific* names into the genuine, or true, and the fpurious, or falfe ones.

The genuine names are thofe which exprefs thofe characters, by means of which the thing becomes a different fpecies; thefe are invariable, and by thefe names the thing is, in fome fort, defcribed. The falfe ones are thofe *fpecific* names which do not, nor cannot diftinguifh the fpecies, called by them, from the others of the fame genus, which may as well belong to fome other fpecies as to that, and which therefore are of no ufe to the ftudent. The true formation of thefe names is on the real characters of the body to be named; but inftead of this thefe falfe ones are formed, from the following accidental, or variable diftinctions.

1. From the fifh being common, or fcarce. On this difference are founded the diftinctions of fifh, for inftance, in their *fpecific* names, into *vulgaris* and *rara*; and thus authors abound with *acus vulgaris*, *lupus vulgaris*, *boops rara*, and the like. Names are meant to convey fome idea of the nature of the thing, but what do thefe convey? or how is the perfon, who is fhewn a fifh he does not know, to find out whether it be fcarce or common?

2. From the number of the fpecies of fome genus. Thus we find *acus prima*, and *acus altera*, and the *afellus primus*, *fecundus*, *tertius*, and fo on, in many other genera: thefe convey even lefs than the former.

3. Some of the *fpecific* names of the antients are formed of the place, or habitation of the creatures. Of this nature are the *alburnus lacuftris*, the *apua phalerica*, the *brama marina*, the *lampetra fluviatilis*, and a thoufand others; either alluding to the nature of the water, or peculiar place where the fifh firft met with, of this genus, chanced to be found.

4. Some are formed on the value or bafenefs of the fifh. Of this kind are the *falmo nobilis*, the *albula lauta*, the *afellus lufcus*, the *falmo fpurius*, fo called, from its not having the fine flavour of the other; and fo on.

5. The different bignefs is another foundation of thefe names: thus we have the *acus major*, *albula parva*, *bugloffus maximus*, *harengus minor*, and the like.

6. The colour, though very variable, or only confined to one part of the fifh, has given occafion to others; and in thefe it has been expreffed, as if generally diffufed over the fifh. Thus the *albula cærulea* has only a part blue, though the name feems to exprefs that the whole is fo: the *afellus flavefcens*, and *virefcens*, are names of the fame kind, the yellow and green expreffed in them not being general, but only partial: the *torpedo maculofa*, and *non maculofa*, feem to exprefs two fpecies different only in the fpots, whereas thefe fpots appear and difappear at times in the fame *fpecies*. All thefe, and many hundred others, founded on the fame principles with thefe, are falfe and fpurious, and not at all anfwering the intent of *fpecific* names, nor diftinguifhing the fifhes one from another. An unknown fifh carries no figures of 1, 2, 3, &c. marked on it, to fay whether it be the firft, fecond, or third of the author who defcribes it; nor can it be known, at fight, whether it be a native of falt or of frefh water, whether it lives in rivers or in ponds, and whether it be of American, Afiatic, or European origin; neither can the tafte, the nature, or the manner of life of the fifh, be feen on the outfide of its body: all thefe, therefore, are to be banifhed from the names, though they make a proper part of the hiftory of the fpecies. On firft meeting with a fifh, can any man judge whether it be the greateft, the middle, or the fmalleft of its kind, or fay whether it is longer or broader than the reft, before he knows them? nor can the mention of a colour fignify any thing, when it is not faid what part of the fifh is tinged with it. As the properties, on which thefe *fpecific* names are founded, cannot be known till the fifh is well known, and as the ufe of the name is the leading the perfon, yet ignorant, to know it, it follows that all thefe names are falfe, frivolous, and abfurd, and yet thefe are the names by which almoft all the old authors have called them.

The true, and genuine *fpecific* name, on the other hand, is that which diftinguifhes the fifh called by it, at firft fight, from all the others of the fame genus; or which, if it require thought and deliberation, yet requires no perfon's knowledge of the fifh.

Thefe *fpecific* names are to be taken from fome external part, which in that peculiar fpecies differs from thofe of all the others, either in regard to excefs, defect, number, proportion, or invariable colour.

 The

The *fpecific* names, taken from the excefs of the parts, or from fome particular parts which that fpecies has, and which the others want, are preferable to all others. The principal parts, which fometimes are in excefs, fometimes are deficient, and therefore give the proper origin to thefe names, are thefe. The *cirri*, or long-fhaped flefhy filaments hanging from the mouth; the tubercles, which in the heads of fome fifhes imitate horns; the prickles which are on the heads, and other parts; and the prominences, and other foft apophyfes; and other fuch remarkable things, in whatever part of the body. Inftances of proper *fpecific* names, founded on the excefs or defect of thefe parts, are thefe. *Gadus ore cirrato*, and *gadus c'rris carens. Cottus cornubus quatuor in capite. Cottus cornubus capitis carens*, &c.

After thefe, the beft names are thofe which are taken from the number of certain parts differing in excefs, or fmall numbers, in the feveral fpecies. The fins, and their bones, and the prickles of them, are parts which give thefe names, as alfo the fpines on the heads and bodies of fome fifhes, and the *lineæ laterales*, or fide lines, and the teeth.

Of this kind are thofe expreffive *fpecific* names of the *gadus dorfo dipterygio, gadus dorfo tripterygio, gafterofteus aculeis decem*, &c.

Others of thefe names are taken from the proportion of fome two parts one to another. The difference of this kind is generally in regard to length; and the parts alluded to, are the jaws, the teeth, *&c.* Of this fort are the *clupea mandibula fuperiore longiore*, and the like. In the fquali, and fome other cartilaginous fifhes, the upper part of the tail is always longer than the under part; but as this holds in all the genus, there can be no ufe made of it as a *fpecific* character.

Others of thefe names are made from the figure of fome particular part, different from the reft of the genus. The parts alluded to in thefe names are generally thefe; the fnout, the back and belly, the tail, the lateral line, and the fixed fpots and colours. The fnout of any fpecies, when different from that of the others of the fame genus, in being conic, depreffed, or compreffed, or long and cylindric, gives great opportunity of good names of this kind. Thus we have the names of *coregonus roftro conico*, and *coregonus roftro depreffo*, and the like. The back and belly, when plane ridged, or carinated, give occafion to *fpecific* names in the fame manner; the cyprini in particular give us inftances of this. The tail gives alfo occafion to many names, as it is cufpidated, rounded, ftrait, lightly hollowed, or forked; and the lateral lines give the fame occafions of names, as they are ftrait, crooked, fingle, double, *&c.* The fpots, provided they are permanent, are good for the bafis of *fpecific* names, expreffing whether they are round or long, large or fmall, ftrait, or tranfverfe. The fituation of the fins, and other parts, is generally fo regular in all the fpecies of the fame genus, when that genus is naturally eftablifhed, that very little can be done in the making names from them as *fpecific* ones; but this fituation of the parts is of the utmoft ufe in the generical diftinctions.

All *fpecific* names, founded on thefe characters, are genuine and proper, and fupply real notes for the diftinguifhing the fpecies; and whoever will examine together all the fpecies of any one genus, however badly named by the old authors, will find, in all the really diftinct fpecies, marks fufficient for the making fuch names as are here prefcribed. No fifh can want thefe, fince its being a diftinct fpecies from the reft confifts in fome of the articles, on the defcription and diftinction of which that name is to be formed. *Artedi*'s Ichthyology.

SPECTABILES, among the Romans, a title of honour given to the fecond rank or degree of nobility under the Roman emperors, being unknown in the time of the republic. There were other two degrees; the firft had the title of *illuftres*, and the third that of *clariffimi*. *Pitifc.* in voc.

SPECTER, in conchyliology, a name given by the French naturalifts to a fpecies of *voluta*, on which there are feveral reddifh broad bands, compofed of loofe and irregular figures; the ground colour is a fine white. They are called by Latin writers *concha fpectrorum*. See CONCHA.

SPECTRORUM *candela*, in natural hiftory, a name by which fome have called the belemnites. See the article BELEMNITES.

SPECULA, among the Romans, were places whence a good view might be had of what was doing at a diftance. The word is particularly ufed to fignify watch-towers and beacons. *Pitifc.* in voc.

SPECULARES, in natural hiftory, the name of a genus of foffils of the clafs of the talcs.

The word is derived from the Latin, *fpeculum*, a looking-glafs; the bodies of this kind being naturally of bright gloffy and polifhed furfaces, and in the thicker maffes not tranfparent, but reflecting the images of things.

The *fpeculares* are talcs, compofed of vifibly feparate plates of extreme thinnefs, and each fiffile again into a number of others yet finer. See Tab. of Foffils, Clafs 1.

The bodies of this genus are the common Mufcovy talc; the *fpecularis lucida fufca*, or brown talc, a fpecies little inferior to the former in beauty, and found in Germany and England; and the *fpecularis amethyftina*, called *talc rouge*, or red talc, by the French. This is found in Mufcovy and Perfia, and no where elfe, as far as is yet known, and is often imported into France in maffes, which are of a beautiful purple: we have of it brought into England, but only in thin flakes, fit for the covering miniature pictures. In thefe flakes it has none of the rednefs natural to it in the lump, but is the fineft and moft tranfparent of all the talcs. *Hill*'s Hift. of Foffils, p. 71. 74.

Pliny, and other of the antient writers, as well as feveral of the moderns, ufe the term *fpecularis lapis* for that fpecies of talc, commonly known by the name of *ifinglafs*, or *Mufcovy glafs*.

This has been a fubftance in great ufe among mechanics, from the earlieft times we have any accounts of. It is found in broad flat maffes of ten or twelve inches in breadth, and from half an inch to three inches in thicknefs; and is compofed in thefe of an almoft infinite number of broad and beautifully even plates, or flakes, laid with a perfect regularity on one another, and feldom parting naturally from each other, though by art they may be divided, almoft without end, into broad and extremely thin laminæ. Thefe are very flexile and elaftic, and make no effervefcence with aqua fortis. By the laft of thefe properties they are diftinguifhed from the plated fpars which fome have confounded with them, and by their elafticity from all other foffile bodies.

It is found in many parts of the world. The ifland of Cyprus abounds with it. It is very common alfo in Ruffia, and has of late been difcovered to abound in the Alps, the Apennines, and many of the mountains of Germany. It is imported in large quantities into England, and is ufed by the lanthorn-makers inftead of horn, in their nicer works; by the painters to cover miniature pictures; and by the microfcope-makers to preferve fmall objects for viewing by glaffes. The antients ufed it inftead of glafs in their windows. *Hill*'s Hift. of Foffils, p. 72.

SPECULARIA, among the Romans, a kind of window-cafements, which were ufed before glafs was introduced for this purpofe. They confifted of tranfparent ftones, called *lapides fpeculares*. *Pitifc.* in voc. See SPECULARIS *lapis*, *Cycl.* and *Suppl.*

SPECULARIS *lapis*. See SPECULARES, fupra.

SPECULATION (*Cycl.*)—SPECULATION-*fhell*, in natural hiftory, a name given by the French writers to a very beautiful fpecies of the *voluta*, ufually called by us the *Guinea-fhell*, from its being brought from that part of the world. See the article VOLUTA.

SPECULATIVE (*Cycl.*)—SPECULATIVE *mufic*, called by the Italians *mufica fpeculativa*, or *theorica*, that which treats only of the founds, examines their natures, properties, and effects, without regard to the executive part.

SPECULUM (*Cycl.*)—SPECULUM *linguæ*, a chirurgical inftrument. See GLOSSOSPATHA.

SPECULUM *indicum*, an affected term ufed by fome chemical writers to exprefs filings of iron.

SPEEDWELL, *veronica*, in botany. See the article VERONICA.

We have feveral of the exotic kinds of this plant propagated in the gardens of the curious. They may all be raifed from feeds, but their roots encreafe fo faft, that they are ufually propagated by parting them. The beft feafon for doing this is in September, and the fummer following they will produce their flowers in full perfection. They will grow in any fituation, but they thrive beft in a frefh foil, that is not too wet. They require no care but the being kept clear from weeds, and having their roots parted every autumn, otherwife they multiply too faft, and both choak up themfelves, and injure whatever is near them. *Miller*'s Gard. Dict.

SPEISSE, in mineralogy, a name given by the Germans, and other workers on cobalt, to a fort of impure regulus of bifmuth, fometimes occurring in their proceffes.

It is not uncommon for ores of bifmuth to be mixed with the cobalt in the fmalt-works. Both this ore and the cobalt yield the blue vitrifiable earth of which fmalt is made, but in one of them it is blended with arfenic, and in the other with the bifmuth. The feparating it from thefe two minerals requires different proceffes, and the workmen therefore feparate the two minerals, and work each by itfelf; but it fometimes happens that the ore of bifmuth is fo like to the true cobalt, that it cannot be diftinguifhed by the eye, and fo intimately mixed with it, that it cannot be feparated from it; in this cafe the whole is expofed to the fire together, and after the arfenic is fublimed in form of meal, there remains a coarfe and impure regulus of bifmuth, which having mixed itfelf with the earth of the cobalt, and other extraneous fubftances, is of a reddifh white colour, and very impure and friable. This gives them the trouble of a fecond operation, by which they feparate the pure regulus of bifmuth, and the remainder being a mixture of its earth and that of the cobalt, is run together into the blue glafs, called *fmalt*, the earth of bifmuth ore being of the fame nature with that of cobalt. Philof. Tranf. N° 396. p. 199.

SPELTA, in the materia medica, a name ufed for the grain of the zea dicoccos, commonly called *fpelt corn.* *Dale*'s Pharm. p. 261.

SPELTER (*Cycl.*)—This mineral has been applied lately to fo large a work as the cylinder of a fire-engine, by Mr. Ford of Colebrook Dale in Shropfhire: it runs eafier, and cafts as true as brafs, and bores full as well, or better, when warmed a little. While cold it is as brittle as glafs, but the warmth of the hand will make it fo pliant, that a fhaving of it may be wrapt round the finger like a bit of paper. This metal never rufts, and therefore works better than iron; the ruft of which, upon the leaft intermiffion of working, refifts the motion of the pifton. Philof. Tranf. N° 482. fect. 6.

SPENT, at fea. The feamen fay a fhip hath *fpent* any maft, or yard, when it is broken down by foul weather, or any fuch accident; but if it be done by an enemy's fhot in a fight, they fay, *fuch a yard*, or *maft, was fhot by the board.*

SPERAGE, *afparagus*, in botany. See ASPARAGUS.

The propagation of this ufeful plant is from feed; and as much of the fuccefs depends upon the goodnefs of the feed, it is much better to fave it than to buy it at the fhops. The manner of faving it is this: mark with a ftick fome of the faireft buds, and when they are run to berry, and the ftalks begin to dry and wither, cut them up; rub off the berries into a tub, and pouring water upon them, rub them about with your hands, the hufks will break and let out the feed, and will fwim away with the water in pouring it off; fo that in repeating this two or three times, the feeds will be clean wafhed, and found at the bottom of the tub. Thefe muft be fpread on a mat to dry, and in the beginning of February muft be fown on a bed of rich earth: they muft not be fown too thick, and muft be trod into the ground, and the earth raked over them fmooth; the bed is to be kept clear of weeds all the fummer, and in October, when the ftalks are withered and dry, a little rotten dung muft be fpread half an inch thick over the whole furface of the bed.

The fpring following the plants will be fit to plant out for good; the ground muft therefore be prepared for them by trenching it well, and burying a large quantity of rotten dung in the trenches, fo that it may lie at leaft fix inches below the furface of the ground: when this is done, level the whole plot exactly, taking out all the loofe ftones; this is to be done juft at the time when the *afparagus* is to be planted out, which muft be in the beginning of March, if the foil is dry, and the feafon forward; but in a wet foil, it is better to wait till the beginning of April, which is about the feafon that the plants are beginning to fhoot.

The feafon being now come, the roots muft be carefully taken up with a narrow-pronged dung-fork, fhaking them out of the earth, and feparating them from each other, and obferving to lay all their heads even, for the more convenient planting them, which muft be done in this manner.

Lines muft be drawn, at a foot diftance each, ftrait acrofs the bed, thefe muft be dug into fmall trenches of fix inches deep, into which the roots muft be laid, placing them againft the fides of the trench with their buds in a right pofition upwards, and fo, that when the earth is raked over them, they may be two inches under the furface of the ground. Between every four rows a fpace of two feet and a half fhould be left for walking in, to cut the *afparagus*. When the *afparagus* is thus planted, a crop of onions may be fown on the ground, which will not at all hurt it.

A month after this the *afparagus* will come up, the crop of onions muft then be thinned, and the weeds carefully cleared away. About Auguft the onions will be fit to pull up. In October following cut off the fhoots of the *afparagus* within two inches of the ground, clear well all weeds away, and throw up the earth upon the beds, fo as to leave them five inches above the level of the alleys. A row of colworts may be planted in the middle of the alleys, but nothing muft be now fown on the beds. In the fpring the weeds muft be houghed up, and all the fummer the beds kept clear of weeds. In October they muft be turned up, and earthed again, as the preceding feafon.

The fecond fpring after planting, fome of the young *afparagus* may be cut for the table. The larger fhoots fhould only be taken, and thefe fhould be cut at two inches under ground, and the beds every year managed as in the fecond year. *Miller*'s Gard. Dict.

SPERMACOCE, the name of a plant which, according to the Linnæan fyftem of botany, makes a diftinct genus, the characters of which are; that the calyx is a very fmall perianthium, divided by four notches at its extremity, placed on the germen, and remaining when the flower is fallen. The flower confifts of one leaf, which forms a tube longer than the flower, with its extremity divided into four fegments, fomewhat bent back, and obtufe. The ftamina are four pointed filaments, fhorter than the flower. The antheræ are fimple. The germen of the piftil is roundifh, flatted, and fituated below the receptacle. The ftyle is fingle, but bifid at the top. The ftigmata are obtufe. The fruit is compofed of two oblong capfules growing together, convex on one fide, and flat on the other, obtufe, and each furnifhed with two horns. The feeds are fingle and roundifh. *Linnæi* Gen. Plant. p. 25.

SPERMATOPŒA, a name given to fuch medicines as are fuppofed to encreafe the femen.

SPERVERIUS, in zoology, a name by which Bellonius, and fome other authors, have called the fparrow-hawk, more commonly known by the names of *nifus*, and *accipiter fringillarius*. *Ray*'s Ornitholog. p. 52. See the article FRINGILLARIUS *accipiter*.

SPHACELUS (*Cycl.*)—In cafes of a perfect *fphacelus*, or mortification, where the parts are become abfolutely dead, and wholly without fenfe, and foft, fo as to retain the impreffions of one's fingers ends, and are plainly fetid and corrupted, all the medicines in the world will be ineffectual to reftore the part to its life and fenfe again; and all that remains to be done, is the one miferable remedy of preferving the reft of the body, by cutting off that part, to prevent the mortification from fpreading farther. A different method is to be taken, however, in this operation, according to the degree of the fymptoms, and nature of the part affected.

If only fome extremity of the foot, tarfus, metatarfus, or inftep, or only the bare fkin and fat are *fphacelated*, which is fometimes the cafe, the whole foot is not to be amputated in that cafe, but preferving the limb entire, the furgeon is only to remove that part which is vitiated; and that is frequently beft of all done by fuppuration, or if not to be effected by that means, may be attempted by the cauftic. When it is to be done by fuppuration, that is to be brought on as faft as poffible, and when it is done, the cruft or efchar of the ulcer is to be feparated from the found parts with proper caution.

To haften effectually a fuppuration in thefe cafes, nothing is fo ferviceable as the making numerous long and deep fcarifications near the found parts; and afterwards the incifed parts are to be well anointed with the common digeftive ointment, and after that treated with the balfamic cataplafms and fomentations, in common ufe on the like occafions.

A fomentation, alfo very ferviceable in thefe cafes, is made by mixing, in a quart of a decoction of fcordium, or of barley-water, vinegar of rue fix ounces, fpirit of wine with Venice treacle four ounces, and an ounce, or two ounces of common falt: this is to be applied hot with compreffes to the part, and frequently repeated, till it is feen that the diforder fpreads no farther; which is known to be the cafe, when we fee the tumor of the vitiated parts fubfide, and the edges of the found parts become tumid all round; and on the fecond or third day after this a fuppuration is ufually formed, and the found parts gradually become feparated from the vitiated. After this, to foften and promote a fpeedy feparation of the efchar, the following cataplafm is always found highly ferviceable. Take of fcordium two handfuls, mallows, marfhmallows, and henbane, of each one handful, lavender-flowers half a handful; let thefe be boiled to the confiftence of a cataplafm in vinegar, or oxycrate, and then in that ftate add to them three ounces of flour of linfeed, one ounce of linfeed oil, and two ounces of fal armoniac. This is to be applied warm over the whole, and retained in a proper degree of heat, as long as fhall be found neceffary, by means of a brick boiled in water, and applied wrapped in a linnen cloth, or fome other like means. After thefe methods have been ufed, and the whole furrounding fkin is gently tumefied with rednefs, a cruft, or efchar is then formed by degrees, and the found flefh begins to feparate from the reft: by this we know that the diforder has done fpreading, and that an entire feparation of the vitiated parts will very fhortly follow.

When this feparation fhews itfelf beginning, it muft be promoted as much as poffible, by dreffing the part with the common digeftive, either alone, or mixed with Venice treacle, which muft be retained on between the found and dead parts. To make way for this, it is fometimes neceffary to divide them a little by the lancet; and when that is done, and the dreffing has been applied, the before defcribed cataplafm fhould be again laid on warm; and in all the fucceeding dreffings, whatever is found loofe of the dead part muft be carefully removed. And if it be neceffary, from the adhefion of the vitiated parts to the found, to ufe the fciffors, or fcalpel, to divide them, this is always to be done with very little, either of pain or of danger; it will then be proper to drefs the part with the digeftive, and a plafter of diachylon, or the like, over it, till the corrupted parts are entirely caft off, and the ulcer appears perfectly well cleanfed, and then the cure is eafily perfected in the common way.

This is the gentler, and more common method; fome furgeons, however, from the tedioufnefs of it, have recourfe directly, in thefe cafes, to the cauftic. They anoint either the edges only, or elfe the whole of the corrupted part, every day, with butter of antimony, or the cauftic ftone liquefied, till the living parts are furrounded by a fort of efchar, applying afterwards the cataplafms before defcribed, or others

others of the fame kind, to prevent the diforder from fpreading; and to make the corrupted parts feparate from the found, the corrofive lixivium of Boerhaave is greatly in repute, and much ufed on thefe occafions. It is made of three ounces of very ftrong quick-lime, mixed with nine ounces of pot-afhes, firft ground feparately to powder, and afterwards mixed, adding a little water, they are then to be put into a glafs veffel, and fet in a cellar to run by deliquium.

As foon as they are found to become fluid, the matter muft be put into a filtre of coarfe paper, and the clear liquor that runs through muft be kept for ufe. It is to be ufed by dipping a brufh or feather into it, and rubbing it over the part affected once or twice a day; or fine linnen-rags may be wetted with it, and applied all over the part; not forgetting, however, at the fame time, the ufe of the before ordered cataplafm: this application is to be continued till the corrupted part begins to caft off in crufts or fcales; and when this is the cafe, it muft be dreffed with the common digeftive, and when perfectly cleanfed, healed with a vulnerary balfam.

Another cauftic, highly commended by Bellofte in thefe cafes, is made by diffolving one part of crude mercury in two parts, either of fpirit of nitre, or of aqua fortis. This is to be rubbed over the parts as the former, and will occafion a fpeedy feparation. Several great authors, however, advife the ufing the knife, and actual cautery in thefe cafes, dividing and burning down to the found parts; but the cruelty of this method, and the pain, and fometimes danger that attend it, make the methods of cure by fuppuratives, and mild cauftics, much to be preferred: indeed, the furgeons in general are not now fo fond of calling in the actual cautery as formerly.

Finally, when the *fphacelus* is fo deeply affixed in any part of the upper or lower extremity, that it has penetrated thro' the mufcles as far as the bone, and has either refifted the force of all medicines, or the proper time for the applying them has been neglected; in this cafe, to preferve the reft of the body, the injured part muft be amputated. *Heifter*'s Surgery, p. 217.

SPHÆCULÆ, among the Romans, were tickets of wood, *tefferæ ligneæ*, by which the emperors fcattered their prefents to people of both fexes in the theatre, or *circus*. *Pitifc.* Lex. Ant. in voc.

SPHÆROMACHIA, Σφαιρομαχια, in antiquity, a particular kind of boxing, wherein the combatants had balls of ftone or lead in their hands, which were called σφαῖραι. *Potter*, Archæol. Græc. lib. 2. cap. 21. Tom. I. p. 448. See the article BOXING.

SPHAGITIDES, a name given by fome authors to the jugular veins.

SPHAGNUM, in botany, the name of a genus of moffes, the characters of which are thefe: They produce heads or capfules only of one kind, which differ alfo from thofe of all the other moffes, in that they have no calyptra, or other covering: thefe ftand on very fhort pedicles, and are therefore fo guarded by the leaves, as not to need any other covering. The *fphagna* are divided into two orders, the one comprehending the branched kinds, and the other the unbranched ones: thefe are diftinguifhed by fome by the terms *cauliferous* and *acaulous*. See Tab. of Moffes, N° 8. *Dillen.* Hift. Mufc. p. 242.

Of the firft order there are nine known fpecies. 1. The larger foft and hollow-leaved bog-*fphagnum*. This grows in wet places in vaft beds, and rifes to a foot high, with clufters of leaves at the heads of all the branches. 2. The foft bog-*fphagnum* with finer leaves. This is as tall, or more fo, than the former, but is much flenderer, and the leaves much fmaller and finer. The firft is ufually of a dead white, and this laft of a fomewhat reddifh hue. 3. The bright green-pointed *fphagnum* with oval heads. This grows in large tufts in the boggy places on the Welch mountains. 4. The rough *fphagnum* with red heads. The ftalks of this are not above an inch long, and not branched, but folded, and interwoven one with another into thick tufts. It ufually grows upon rocks, but fometimes on the ftumps of old trees. 5. The hoary nodofe *fphagnum*. This is all over hairy, the ftalks are fomewhat longer than thofe of the former kind, and the heads are ripe in December. This ufually grows on the ftumps of old trees. 6. The *fphagnum* with numerous heads, all bending one way. This is very common on the ftumps of old trees, and produces its heads in November. It is of a very lively and pleafant green. 7. The plain-feathered *fphagnum*. This is an elegant fpecies, and grows on the bodies of old trees in Patagonia. 8. The wavy-feathered *fphagnum* with hairy heads. This is of the fame country with the former, and grows to three or four inches in length. 9. The wavy-feathered *fphagnum* with fcaly heads. This is found on the trunks of trees in the woods of Germany. *Dillen.* Hift. Mufc. p. 253.

Of the *fphagna* of the fecond order, or thofe which have no branched ftalks, there are only four known fpecies. 1. The dwarf hair-leaved *fphagnum*. This is the fmalleft and fineft of all the plants of this clafs, and is common in fmall tufts about way-fides in many places. 2. The larger dwarf bulbous *fphagnum*. This grows only to the height of a few lines, and is compofed of numerous leaves, furrounding one another fo, as to form feveral bulbs. The heads are eafier to be diftinguifhed by the touch than the fight, for they lie hid between the leaves, and are fmaller than poppy-feeds. 3. The leffer dwarf bulbous *fphagnum*. The leaves of this are much fmaller than thofe of the preceding kind. 4. The largeft dwarf *fphagnum* with briftles. The capfules of this fpecies, as well as the leaves, are much larger than thofe of any other of the acaulous kinds, and the middle rib of every leaf runs out into a kind of briftle.

SPHENOIDES (*Cycl.*)—The *fphenoidal*, or cuneiform bone, is fituated in the lower part of the cranium, a little toward its forepart, making the middle or bafis of the fkull, and thence taking its name of *os bafilare*.

It is of a very odd figure, its greateft extent is tranfverfe, and it may in fome manner be faid to reprefent a bat with its wings extended. Its pofterior, or thickeft part, by which it is joined to the apophyfis of the os occipitis, may be called its body; the reft of it is wholly made up of eminences and cavities. And in order to examine thefe methodically, the bone muft be divided into two fides, the one external, the greateft part of which may be feen in one entire fkull, the other internal, which does not appear till the fkull is opened.

The eminences on the outfide are thefe. Two temporal apophyfes, which are the largeft of all the proceffes of this bone, and at the greateft diftance from each other, called *the great wings of the os fphenoides*, and thefe are fometimes, though rarely, feparated from the reft of the bone by tranfverfe futures. Two orbitary apophyfes, which form a confiderable portion of the orbit next the temples. A fmall fharp procefs, formed like a bird's bill between the orbitary apophyfes. Two pterygoide apophyfes, each of which is divided into two alæ: one internal, which is the largeft, the other external, the lower end of which is in the fhape of a hook; and each of thefe alæ is again divided into two fides, the one internal toward the palate; the other external toward the temples. Two fpinal apophyfes. A little anterior eminence above the fharp procefs, for the articulation of this bone with the os ethmoides; but in fome fubjects, inftead of this eminence, there is only a little notch.

The external cavities of this bone are two portions of the temporal foffæ; two pterygoide foffæ; the lower ends of thefe are divided by a little notch, or flit, of an irregular figure, which may be called the *fiffura palatina*: a little oblong foffula at the root of the internal ala; two fuperior orbitary, or *fphenoidal* fiffures; a little notch at the end of each of thefe fiffures, for the paffage of an artery of the dura mater; two temporal notches; two maxillary notches, the edges of which help to form the two inferior orbitary fiffures, which may be called *fiffuræ fpheno-maxillares*: two holes for the fuperior maxillary nerves; two other holes on one fide of the former, called *pterygoide*, which, in an entire fkull, are hid by the other bones: two oval holes, for the inferior maxillary nerves; two little fpinal holes, each of which tranfmits an artery of the dura mater, but fometimes thefe are only notches; a little hole between the two maxillary holes; and a little groove on one fide of the fpinal apophyfis, which forms part of the euftachian tube.

The internal eminences are two thin fharp tranfverfe apophyfes, which form the fuperior orbitary fiffures, called *the little wings of the fphenoidal bone*; a little procefs, in fome fubjects, between thefe two thin apophyfes, for the articulation with the os ethmoides, which in fome other fubjects is a notch. Four clynoide apophyfes, two anterior, two pofterior; which laft are fometimes united in one, and fometimes run forward all the way to the anterior proceffes, forming a kind of bridge, under which the internal carotid artery paffes at its laft curvature. This paffage has alfo fometimes been found divided into two by a thin bony feptum, befide other varieties; one or two fmall productions where the internal carotid enters the cranium; two little ftyloide proceffes, or hooks, which in fome fubjects join the extremity of the os occipitis, before the perfect union of thefe bones.

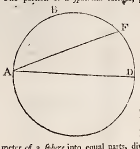
The internal cavities are two portions of the large middle foffæ of the bafis cranii; two fuperior, orbitary or *fphenoidal* proceffes; two optic holes; a fmall fuperior, orbitary hole, near the end of each *fphenoidal* fiffure, which is often no more than a notch; a fmall groove at the extremities of the fame fiffures; a depreffion between the clynoide apophyfes, called *fella fphenoidalis*, *fella turcica*, and *foffa pituitaria*. Here are alfo feen almoft all the holes mentioned on its outfide, and it appears that the fuperior maxillary hole ought more juftly to be called a fhort canal. Befide thefe, there are alfo two very confiderable cavities, called the *fphenoidal finufes*, fituated in the thick portion of this bone, under the anterior part of the fella turcica, and middle fpace between the two optic holes, reaching as far as the fharp procefs, or bill, already defcribed; thefe are commonly divided by a bony feptum, and they open before on each fide of the fharp procefs,

proceſs, juſt behind the ſuperior conchæ of the noſe, or oſſa convoluta ſuperiora.

The figure, ſize, openings, and ſeptum of theſe vary greatly; ſometimes one is wanting, ſometimes both are ſo; ſometimes there are ſeveral cells without any ſeptum, and ſome times the ſeptum is placed more on one ſide than the other. The ſubſtance of this bone is for the moſt part compact, having very little diploe; and what there is of this lies in diſtinct parts of the bone, *viz.* in the thick portion behind the ſella turcica, toward the ſymphyſis with the occipital bone, and in the orbitary apophyſes in a ſmall quantity. It is articulated with all the other bones of the cranium, with the oſſa malarum, oſſa maxillaria, oſſa palati and vomer. *Winſlow's* Anatomy, p. 26.

SPHERE (*Cycl.*)—A *ſphere* is equal to four times the cone, the baſe of which is equal to the generating circle, and the height of which is equal to the radius. Or a hemiſphere is equal to twice the cone of the ſame baſe and height. And a cylinder, of the ſame height and baſe, being triple of the cone, it follows, that the hemiſphere is two thirds of the cylinder, and conſequently the whole *ſphere* two thirds of the circumſcribing cylinder. *Archim.* de Sph. et Cyl.

The portion of a *ſpherical* ſurface, generated by the revolution of an arch ABF, about the diameter AD of a circle, is equal to the area of a circle deſcribed with a radius equal to the chord AF.



The ſurfaces therefore generated by arches, terminated at A, are as the ſquares of their chords, or as their verſed ſines.

Hence parallel planes, which divide the diameter of a *ſphere* into equal parts, divide the ſurface of the *ſphere* into equal parts at the ſame time. *Archim.* de Sph. et Cyl.

SPHERICAL (*Cycl.*)—SPHERICAL *numbers*. See CIRCULAR *numbers*, *Cycl.*

SPHEROID (*Cycl.*)—Dr. Halley has demonſtrated, that in a ſphere Mercator's nautical meridian line is a ſcale of logarithmic tangents of the half complements of the latitudes[b]. But as the earth has been found to be a *ſpheroid*, this figure will make ſome alteration in the numbers reſulting from Dr. Halley's theorem. Mr. Mac Laurin has therefore given us a rule, whereby the meridional parts to any *ſpheroid* may be found with the ſame exactneſs as in a ſphere. We have alſo an ingenious treatiſe of Mr. Murdoch's on the ſame ſubject—[[b] See Phil. Tranſ. N° 219. Mr. Cotes has alſo demonſtrated the ſame propoſition, Harm. Menſ. p. 20, 21.] A ſphere, whoſe diameter is equal to the great axis of a *ſpheroid*, is to that *ſpheroid* in the duplicate ratio of the axis to its conjugate. Hence the *ſpheroid* is quadruple of a cone, the height of which is the ſemi-axis, and the baſe of which is equal to a circle deſcribed upon the conjugate axis as its diameter. *Mac Laurin's* Fluxions Introd. p. 16.

SPHINCTER (*Cycl.*)—SPHINCTER *cutanea*, in anatomy, a name given by Laurence, and ſome others, to the muſcle of the anus, called by Albinus and Winſlow *ſphincter internus ani*.

SPHINCTER *inteſtinalis*. See INTESTINALIS *ſphincter*.

SPHINCTER *labiorum*, in anatomy, a name given by Douglas, and ſome others, to the muſcle of the mouth, called by Riolanus and Albinus *orbicularis*, and *orbicularis oris*, and by Cowper *conſtrictor labiorum*.

SPHINCTER *palpebrarum*, in anatomy, a name given by Molinet, and ſome others, to the muſcle of the eyelids, called by Winſlow and Albinus the *orbicularis palpebrarum*, and *orbicularis*. See the article ORBICULARIS.

SPHINX, (*Cycl.*) in the hiſtory of inſects, a name given by Mr. Reaumur to a very ſingular ſpecies of caterpillar deſcribed in the ſecond volume of his hiſtory of inſects.

The reaſon of the author's having given it that name, is, that when it is not eating it erects its head, and with it more than a third part of its body, into a perpendicular ſituation upon the leaf on which it was before laid all along; it keeps itſelf a long time in this ſituation, looking around it with a ſeeming air of fierceneſs. There are alſo a ſeries of broad belts upon the body, which contribute ſomething towards its reſemblance to the figure of that imaginary monſter.

This caterpillar has a horn on the hinder part of its body, which ſeems to be of no ſort of uſe, but merely a trouble to the creature. It is hollow, and encloſes, in the manner of a ſheath, the new horn which is to appear when the creature changes its ſkin. This the author found to be the caſe by cutting it ſeveral times, and always finding within it the new horn cut off alſo at the ſame place, and had often obſerved the great difficulty the animal had in changing its ſkin, when it came to the horn. *Reaumur*, Hiſt. Inſect. Tom. 2.

SPHONDYLIUM, *cow-parſnep*, in botany, the name of a genus of plants, the characters of which are theſe. The flowers are diſpoſed in umbels, and are of the roſaceous kind, being compoſed of ſeveral petals of a heart-faſhioned ſhape, irregular in ſize, and diſpoſed in a circular order round a cup, which afterwards becomes a fruit, compoſed of two large, flat, oval ſeeds, ſtriated, and uſually marginated at the end, and which frequently depoſit their covering, and are marked with black ſpots on the ſides where they touch one another.

The ſpecies of *ſphondylium*, enumerated by Mr. Tournefort, are theſe. 1. The common hairy *ſphondylium*. 2. The hairy *ſphondylium* with purple flowers. 3. The great *ſphondylium*, called by authors *panax Heracleum*, or Hercules's all-heal. 4. The curled-leaved *ſphondylium*. 5. The hairy *ſphondylium* with narrower leaves. 6. The narrow-leaved *ſphondylium* with blackiſh purple flowers. 7. The little Alpine *ſphondylium*. 8. The ſmooth Alpine *ſphondylium*. *Tourn.* Inſt. p. 319.

The common *cow-parſnep*, which is frequent in our meadows and paſtures, and flowers in July and Auguſt, is recommended by Dr. Willis, and many others, as one of the beſt nervous ſimples our nation produces, and it is pity that it is not brought more into practice. The ſeed is the part in which its virtues are contained in greateſt perfection, and is a very good medicine in hyſteric caſes, given in powder or infuſion.

SPHONDYLUS, in ichthyology, a name given by Pliny, and others of the old authors, to a peculiar ſpecies of the ſyngnathus, or *acus Ariſtotelis*. It is the ſpecies, called by Artedi *ſyngnathus corpore medio hexagono cauda pinnata*; and by other authors the *acus ſecunda ſpecies*; and by Bellonius and Geſner *typhle marina*. *Pliny*, lib. 32. cap. 11.

SPHONDYLUS is alſo uſed by ſome authors, for the ſtones or bones found in the head of a mullet.

SPHRAGIS, the ſeal-ſtone, a name given by ſome authors to the ſingle joints of the aſteriæ, when found looſe, not joined into a column. See the article ASTERIA.

SPHRAGIS is alſo uſed by ſome of the old Greek naturaliſts, to expreſs the ſpots on the back and ſides of a panther.

The ſkin of this creature is of a pale colour, and theſe ſpots are all dark and round, and look like ſo many regular impreſſions of a ſeal, whence the name *ſphragis*. The Romans called any thing, that was variegated in this manner, *pantherina*; and we meet with the phraſe *menſæ pantherinæ*, uſed to expreſs tables found of ſome wood, which was variegated with round ſpots, in the manner of thoſe *ſphrages* on the back of the panther.

SPHYGMICA, in medicine, a term uſed by ſome for that part of the judgment of the phyſician, which regards the differences of the pulſe.

SPHYRÆNA, in zoology, a name by which ſome authors have called the *ſudis*, or *lucius marinus*, the ſea-pike. *Willughby*, Hiſt. Piſc. p. 273. See the article SUDIS.

SPHYRÆNA *altera*, in ichthyology, a name given by Appian, and ſome other of the old Greek writers, to the *eſox*, or common pike. See the articles ESOX and LUCIUS.

SPICCATO, in the Italian muſic, ſignifies that every note ſhould be well ſeparated from others, and diſtinctly ſounded. It is particularly uſed with regard to inſtruments played with a bow; and denotes that every note muſt have a diſtinct bow from that preceding, or ſucceeding.

SPICULUM, in Roman antiquity, a kind of weapon which ſome will have to be the ſame with the haſta, or ſparus. *Hofm.* Lex. in voc.

SPIDER, *araneus*, in zoology, an inſect of which we have a great number of ſpecies common among us, which all agree in the general marks and characters.

They all have weapons iſſuing out of the mouth, but theſe are of two kinds, according to the two principal diſtinctions of the *ſpiders*. They conſiſt, in ſome, of two ſpiculæ, in the manner of a forked hook: this is their ſtructure in all the kinds which have eight eyes. In others they are compoſed of two forcipated arms, or are divided into two claws, in the manner of the legs of a crab: theſe are the weapons of all thoſe *ſpiders* which have only two eyes.

The bodies of all *ſpiders* are covered with a ſort of cruſtaceous coat, but it is tender and brittle; and in the males of all the ſpecies, the forceps, or weapons at the mouth, are larger and ſtronger than in the females.

All *ſpiders* have two antennæ, placed in the forepart of the head over the mouth: theſe are compoſed like the legs of a number of joints. The head of a *ſpider* is not ſeparated from the ſhoulders by any inciſure, but remains fixed to them as all of one piece.

The eyes of the *ſpider* differ greatly in number, ſituation and figure, in the different ſpecies; and ſometimes the different eyes of the ſame *ſpider* are of different ſizes.

All *ſpiders* have eight legs, which are all inſerted into the breaſt, but in the length and figure of theſe there is as much variety as in the eyes in the different ſpecies of *ſpiders*:

they have all three joints in each leg, but in ſome the foremoſt pair are the longeſt, in others the hinder pair are ſo, and in others ſome of the intermediate pairs.

The belly of the *ſpider* is remarkably divided from the head and ſhoulders, ſo as to adhere only by a thread: this is the caſe in all, except the two-eyed kinds, and in the different ſpecies the body is variouſly painted. The appendages near the anus are very obſervable, they ſerve to ſpin the threads out at. Among the many ſpecies of theſe inſects, ſome are ſmooth, others are hairy, and ſome have a harder, ſome a tenderer ſkin. *Ray's* Hiſt. Inſect. p. 12.

Among the great number of ſpecies of this inſect, theſe are the principal diſtinctions among thoſe which have eight eyes. Some ſpin webs for the catching of flies of a rounded figure; theſe have all their eyes of the ſame ſize and figure; they have four middle ones placed in a quadrangular figure, and the other four beſide theſe, but ſtanding ſomewhat obliquely. The firſt pair of legs of theſe *ſpiders* are always the longeſt, the ſecond pair are the longeſt next to theſe, then the fourth pair, the third being much the ſhorteſt of all. Theſe *ſpiders* are always ſmooth, or nearly ſo, and are elegantly figured on the buttocks. Of theſe ſome always live in the center of the web, others have their habitation in a neighbouring corner. Of the firſt of theſe ſorts we have five ſpecies. 1. The yellowiſh *ſpider* with white back and ſides, and a white head with large pellucid black eyes. This is of a middle ſize, and its legs are variegated with brown and white. The males in this ſpecies are ſlenderer than the females, and of a more reddiſh colour; and in both ſexes the head and ſhoulders are ſomewhat pellucid. 2. The hazel *ſpider* with a croſs on its back, and tubercles on the belly. This ſpecies ſpins very large nets. 3. The ſlender green and gold ſpider with a long body. This is of a middle ſize, and its fore-legs are extremely long. 4. The grey wood-*ſpider* with the body terminating in a three-cornered point. This is a ſmall ſpecies, but it ſpins very large webs. Its belly is black.

Of the ſecond kind of *ſpiders*, which ſpin round webs, and have their habitation at a corner of the web, not in its center, there are five principal ſpecies. Theſe are, 1. the grey full-bodied *ſpider* with various delineations on the back. This is a very large kind; its ſhoulders are hoary, its legs thick, not long and ſpotted. 2. The ſmooth black croſs *ſpider* with an oval body. This is of a middle ſize, its legs are ſhort and ſpotted. It is very common among ruſhes and water plants. 3. The yellow *ſpider* with four great white ſpots, and many ſmall ones. This is one of the largeſt *ſpiders*, and generally builds its habitation on the tops of plants. This is called by Mouffet, and ſome others, the *Colcheſter ſpider:* and there are two other ſpecies which much reſemble it; the one diſtinguiſhed by having a cheſnut-coloured head, and a black belly; the other, by a large brown ſtreak running from the ſhoulders to the tail. 4. The black *ſpider* with figures like oak leaves upon its buttocks. It is a very large *ſpider*. 5. The grey round-headed *ſpider* with foliaceous lines on the buttocks, undulated at the edges. This is a middle-ſized one, and is common about houſes. *Ray's* Hiſt. Inſect. p. 24.

Another genus of *ſpiders* are diſtinguiſhed by their building conglobated webs; theſe are all ſmall, and have the fore-legs longeſt of all, next theſe the hinder pair, and then the ſecond, the third being the ſmalleſt of all.

Of theſe there are ſix principal kinds. 1. The black ſmooth houſe-*ſpider*. This is the largeſt of this genus, and has elevated ſhoulders. 2. The white *ſpider* with an oval body, ſurrounded with a ſcarlet ring. 3. The brown *ſpider* with a round body, ornamented with foliaceous figures. 4. The reddiſh brown wood-*ſpider* with a round body, marked with the figure of a ſtar. 5. The ſmall grey *ſpider* with a black ſpot upon its buttocks. And 6. the ſmall livid *ſpider* with denticulated figures on the rump. This uſually erects its conglobated nets on the top of the branches of furze buſhes.

A third genus of *ſpiders* are diſtinguiſhed by the thickneſs and cloſeneſs of the webs; ſome of theſe inhabit the bottom, or funnel-end of their webs, others live near them, but not in them. Of the firſt genus there are two remarkable ſpecies. 1. The yellowiſh hairy long-legged houſe-*ſpider*. This is of a middle ſize, and its eyes are very black and ſparkling. 2. The great grey *ſpider* with the appendices of the anus very remarkably prominent. This is a very large kind, and is of a livid colour.

Of the ſecond kind of theſe, which live at a diſtance from their webs, there are alſo two principal kinds. 1. The ſmooth cheſnut-coloured, or blackiſh *ſpider* with elegant ſnow-white ſpots. This is of a middle ſize, and has long and ſlender legs. 2. The black *ſpider* with white ſhoulders, and a denticulated white mark upon the back. This is of the middle ſize. Its legs are hairy.

To theſe is to be added the cave-*ſpider* of Mouffet. This is a large black *ſpider* with a very large ſpot, of a deeper and more ſhining black upon the ſhoulders.

A fourth genus of *ſpiders*, is diſtinguiſhed by the ſmallneſs of the webs they build: theſe are, however, of a very cloſe texture, and the creature always lives within them. Of the *ſpiders* of this kind there are three principal ſpecies. 1. The grey woolly *ſpider* with a broad black ſpot on the belly. 2. The plain livid, or yellowiſh *ſpider*. This is ſometimes of the one, and ſometimes of the other of theſe colours, but never has any variegations. 3. The yellowiſh cylindric-bodied *ſpider*. This is a large *ſpider*, and has ſix eyes. This has a long ſeries, or chain of ſpots on the back, and a yellowiſh line or ſtreak on each ſide. *Ray's* Hiſt. Inſect. p. 30. See the articles LUPUS and PHALANGIUM.

The *ſpider* affords to the ſagacious obſerver, as well without as with the aſſiſtance of glaſſes, a great many extremely curious particulars. As the fly (which is the *ſpider's* natural prey) is an animal extremely cautious and nimble, and uſually comes from above, it was neceſſary the *ſpider* ſhould be furniſhed with a quick ſight, and an ability of looking upwards, forwards, and ſideways; at the ſame time; and the microſcrope ſhews, that the number, ſtructure, and diſpoſition of its eyes, are wonderfully adapted to the ſerving all theſe purpoſes.

Moſt *ſpiders* have eight eyes: two on the top of the head or body, for there is no diviſion between them, the *ſpider* having no neck; theſe look directly upwards: there are two more in front, placed a little below theſe, and diſcovering all that paſſes forwards, and on each ſide: a couple more, one whereof points ſideways forward, and the other ſideways backward; ſo that it can ſee almoſt quite round it. All kinds of *ſpiders* have not, however, this exact proviſion; for in ſome we find ten, and in others only ſix, or four. The eyes of the *ſpider* are not pearled; and the field-*ſpiders*, or long-legs, have no more than two eyes.

Whatever be the number of the *ſpider's* eyes, they are however all immoveable and tranſparent, and are ſituated in a moſt curious manner. The beſt way of viewing them with the microſcope, is to cut off the legs and tail, and leave only the head for examination.

All *ſpiders* have eight legs, which they employ in walking, and two ſhorter, called *arms*, which they uſe in ſeizing their prey. All the legs are thickly beſet with hairs; each has ſix joints, and ends with two hooked claws, which are ſerrated on their inſide; by means of theſe teeth, or jags in their claws, they ſeize very faſt hold of any thing, and behind theſe there is a ſort of ſpur, which is perfectly ſmooth. Beſide theſe, nature has allotted to this creature, for the ſeizing its prey, a pair of ſharp crooked claws, or forceps, in the forepart of its head. Theſe ſtand horizontally, and when not exerted for uſe, are concealed in two caſes contrived for their reception, in which they fold like a claſp-knife, and there lie between two rows of teeth, which are likewiſe employed to hold faſt the prey.

Each of theſe claws, or pincers, has a ſmall ſlit near its point, according to Lewenhoek, like that in a viper's tooth, through which he ſuppoſes that a poiſonous juice is, in like manner, thrown out. But Dr. Mead, in his Eſſay on Poiſons, diſſents wholly from this opinion, having never been able, on repeated examinations, to diſcover any ſuch opening, not even in the claws of the great American *ſpider*; which being above fifty times bigger than any of the European *ſpiders*, would more eaſily have diſcovered this opening, if nature had allotted any to this part of the animal. Beſides, repeated obſervations alſo convinced him that nothing dropped out of the claws, which were always dry, while the *ſpider* bit any thing, but that a ſhort white proboſcis was, at the ſame inſtant, thruſt out of the mouth, which inſtilled a liquor into the wound. And the ſame author obſerves, that the quantity of liquor, emitted by our common *ſpiders* when they kill their prey, is viſibly ſo great, and the wounding weapons ſo minute, that they could contain but a very inconſiderable portion thereof, if it were to be diſcharged that way. *Baker's* Microſcope, p. 196.

Spiders frequently caſt their ſkins, which may be found in their webs perfectly dry and tranſparent; and from ſuch ſkins the forceps, or claws, for they are always ſhed with the ſkins, may eaſier be ſeparated, and examined with much greater exactneſs, than in the common *ſpider* while living.

The *ſpider's* manner of weaving its web is very wonderful. The creature has five little teats, or nipples, near the extremity of the tail; from theſe there proceeds a gummy liquor, which adheres to every thing it is preſſed againſt, and being drawn out, hardens inſtantly in the air, and becomes a ſtring, or thread, ſtrong enough to bear five or ſix times the weight of the *ſpider's* body. This thread is compoſed of ſeveral finer ones, which are drawn out ſeparately, but unite together at two or three hairs breadth diſtance from the creature's body. Theſe threads are finer or coarſer, according to the bigneſs of the *ſpider* that ſpins them. Mr. Lewenhoek has computed, that a hundred of the ſingle threads of a full grown *ſpider* are not equal to the diameter of the hair of his beard; and conſequently, if the threads and hair be both round, ten thouſand ſuch threads are not bigger than ſuch a hair. He calculates farther, that when young *ſpiders* firſt begin to ſpin, four hundred of them are not larger than one which is of a full growth; allowing which,

which, four millions of a young *spider*'s threads are not so big as the single hair of a man's beard.

The eggs of some *spiders* are a very pleasing microscopic object; they are round at one end, and flattish at the other, with a depression in the center of the flattish end, and a yellowish circle round it. The colour of these eggs is a pearly or bluish white, and when the young *spiders* hatch, they come out in their perfect form, and run about very nimbly. The female *spider* deposits her eggs, to the number of five or six hundred, in a bag composed of her own web, which she either carries under her belly, or hides in some very safe recess. Philos. Transf. N° 272.

The young *spiders* are always very beautiful objects for the microscope. The current of the blood may be easily discovered in their legs, and part of their bodies; and many other curious particulars occur in their dissection.

There are two or three species of this animal, peculiarly worthy the attention of the curious in microscopic discoveries. 1. A little white field-*spider* with short legs. This is found plentifully among new hay, and its body appears like white amber with black knobs, out of which grow short but sharp prickles. The eyes of these may be very distinctly seen, being very brisk and lively, and some have six, some eight of them: each eye has a pupil of a violet blue, which is beautifully clear and transparent, and is surrounded by a circle of pale yellow. 2. The wandering, or hunting *spider*, that spins no webs, but runs and leaps by fits. This has two tufts of feathers fixed to its fore-paws, which make a very beautiful appearance before the microscope. The variety and beauty of colouring also, all over this little creature, afford a very pleasing sight. 3. The *long-legs*, or shepherd-*spider*. This is a most wonderful creature: it has two fore-claws at a great distance from the head, tipped with black like those of a crab, and opening and shutting like the scorpions; these are serrated or indented on their inside. When all the legs are cut from this *spider*, and it is examined by the microscope, it will be seen that the protuberance on the top of its back is furnished with two fine black eyes. *Power*'s Microf. Obs. p. 13. *Hook*'s Micrography. p. 200.

The venom of many kind of *spiders* is greater than usually supposed: we have, in the Philosophical Transactions, an account of a person in New-England who was bitten by a small *spider* a little above his ankle; he perceived the creature biting, and crushed it to death upon the wound, between his stocking and his leg; in half an hour he felt a pain in that leg, which in another half hour extended itself to the groin, and at the same time he had a creeping pain in the calf of his other leg; and in a quarter of an hour after this it affected his stomach, his back, and his head. The pains were not constant and fixed, but erratic, and very acute, and his pulse was extremely low and heavy. He was relieved, by taking internally spirit and salt of hartshorn in viper-wine, and applying a cataplasm of garlick to the part, and in three or four days wholly recovered.

Boccone mentions a species of large *spider*, common in the island of Sardinia, whose bite proves mortal within the space of a few hours; the whole body usually swells almost immediately, in consequence of this bite. The cure is performed by oil of olives, in which the creature is infused over the heat of a stove. This is a medicine they always keep ready in the house, and while they use this externally, they give large doses of Venice-treacle inwardly, dissolved in strong wine: but many die of this bite, either from the want of power in the remedies, or from their being used too late. *Boccon*. Mus. de Fis.

When *spiders* ascend and descend by their thread, they do not spin a new one at every descent; but whenever they ascend, they wind the thread with their feet into a sort of coil, and when they descend, they only unravel it again. Phil. Transf. N° 482. sect. 16.

Some think the white matter, we often find floating in the a irtowards the end of the summer, is produced by *spiders*. Ibid. See the articles *Air*-THREADS, OPILIO, PHALANGIUM, &c.

SPIDER-*wort*, in botany. See PHALANGIUM.

SPIEI, in the glass trade, an iron instrument, hooked at the end and pointed, with which the workmen take the metal up out of the melting-pots for proofs or essays, to see whether it be fit to work. *Neri*'s Art of Glass, p. 241.

SPIGNEL, in the materia medica, &c. the English name of the plant called by botanists *meum*. See MEUM.

SPIGOLA, in ichthyology, a name given by Paulus Jovius, and some others, to that species of pearch which is generally called the *lupus marinus*. See the article LUPUS.

It is a genuine pearch, and is distinguished from the others by Artedi, by the name of the *pearch* with the thirteen rays in the second back fin, and fourteen in the pinna ani. Authors have called two different fish by this name *lupus marinus*, which conveying no distinct idea of the characters of the fish, was applicable to either as much as the other; but this name of Artedi admits of no equivocation, and must always distinguish the fish.

SPIKE, or *Oil of* SPIKE, a name given by our druggists to an essential oil, much used by the varnish-makers and the painters in enamel; and of some use in medicine.

This *oil*, when genuine, is brought from Provence, and some other parts of France, and is there made of lavender. This plant is called in Provence *aspic*, and thence came the name *oil of aspic*, which afterwards degenerated into *oil of spike*.

The manner of making the *oil* upon the spot is this: when the flowers are perfectly ripe, they put them into an alembic with a great quantity of water, and this they distil after several days maceration: there arises with the water a large quantity of an oil of a fine pale amber colour, and this separated from the water, is the true and genuine *oil of spike*.

The flower of this plant is the part which yields the largest quantity of oil; as is the case with all the plants with galeated flowers, of which the husk or flower-cup usually contains almost all the oil of the plant. The aromatic plants, in general, yield indeed but a small quantity of oil, but the vast abundance of this plant, in these places, makes the expence of gathering it so small, that the *oil* is very cheap. The quantity required on several occasions is, however, much greater than what all the lavender of the country can yield; and the price it is expected to be sold at is so small, that it is not to be wondered that there are several common adulterations of it.

The most usual ways of sophisticating it, however, are two; the one with the spirit of wine, which is esteemed the least hurtful, and the *oil* thus sophisticated is often called the very best of the country. The method Mr. Geoffroy took to discover the cheat was this: he procured a long and narrow vial, of an equal diameter all the way up, into this he first put an ounce of fair water, and to this he added an ounce of the *oil*; he marked the height of the water in the vial, then shook the two liquors together, and they became milky, and heated on the mixture, which alone would have been a sufficient proof that there was spirit of wine in the *oil*. After some standing the liquor became clear, and the *oil* floated at the top, but in a much smaller quantity than might have been expected, there being not more than a quarter of an ounce of it, the rest having been spirit of wine, which mixed with the water, and thus left all the true *oil*, which was only one fourth of the quantity, to float alone on the water, which was greatly encreased in height in the vial. A pint of this *oil of spike*, therefore, contains only four ounces of the genuine *oil*, and twelve ounces of plain spirit of wine.

The second method of adulterating this *oil*, which the same gentleman had suspected, was easily discovered next: for on mixing this quarter of an ounce of pure *oil of spike* with three quarters of an ounce of oil of turpentine, there was produced an ounce of a liquor, which appeared wholly the same with the *oil of spike* commonly sold in the druggists shops. And indeed, much of what is usually sold is worse than this, being no other than oil of turpentine scented with a small quantity of the true *oil of spike*.

The ready way of discovering the *oil*, counterfeited with oil of turpentine, is to wet a paper in it, and set it on fire; the turpentine will here be discovered by the thick smoak it yields, it being, of all vegetable oils, that which yields greatly the thickest cloud in burning: and, on the contrary, that which has been adulterated with spirit of wine, will be distinguished by the same trial, by its yielding a much finer and thinner smoak, and burning with a bright blue flame. If they be tried by firing them in a spoon, that which is adulterated with spirit of wine will burn very bright, and yield no fume at first; but as it grows near the bottom, it will smoak a little, and finally will leave no residuum, except that it varnishes over the inside of the spoon: that adulterated with the oil of turpentine will burn more vehemently, smoak more, and leave a coarser varnish upon the spoon; and if it be of the coarsest kind, that is, if it have been adulterated with badly-rectified oil of turpentine, the fume will be the more abundant, and there will be left in the spoon a fetid matter, resembling melted pitch.

Mr. Geoffroy tried whether, in the business of varnishing, the oil of turpentine alone might not do as well as the *oil of spike*; he found that it dried perfectly well, but that it left a stinking smell upon the work, which never went off; whereas the mixture of this oil, with that of *spike*, makes a smell like neither, and which soon goes off.

An ounce of oil of turpentine, with only twenty drops, either of our common oil of lavender, or the pure *oil of spike*, makes a liquor tolerably well scented, and which serves for the purposes of *oil of spike*. If two drachms of our oil of lavender be added to six drachms of spirit of wine, they immediately mix, and this afterwards mixed in a small proportion with oil of turpentine, makes a sort of *oil of spike*. The most regular method, however, that the artificer can use, if he can get the genuine *oil of spike*, is to mix one ounce of it with three of oil of turpentine, which perfectly fits it for his purpose, and makes it the same with that in common use. The method of making this perfectly pure, is to redistil it in a balneum mariæ; there will thus be pro-

cured an oil highly rectified, and pellucid as water, which will dry away as soon as touched on any thing. The great disadvantage attending the *oil of spike* adulterated with spirit of wine, is, that it will not readily mix with all the sorts of varnish.

Having gone through the properties of *oil of spike*, in regard to varnish, it remains to enquire into them in regard to its other great use in enamel, and to consider the effects of the two usual methods of adulterating it in this work.

The *oil of spike* which wants body, is not at all fit for enamelling, because it dries too suddenly, and does not at all assist the natural dryness of the enamel, which is only a sort of powder of glass; and the particles of this powder, with a fluid of too little body, are not manageable by the artists, so that the colour never is brought to a due consistence: and when the *oil* has too much body, the mixture becomes too tenacious, and is as unmanageable in that extreme as in the other; and this fault is attended with another very great mischief, which is, that the fume raised by this *oil*, when heated, is often so gross, as to destroy the beauty of the colours. In short, thick oil of turpentine is always destructive of enamels by its smoak.

The true composition for enamelling is *oil of spike* mixed with spirit of wine, but the proportions must be nicely regulated from repeated trials: for if the quantity of the spirit be too large, it is apt to separate itself from the *oil* and colour in the drying, and this always spoils the gloss and beauty of the work. Artificers observe, that *oil of spike* does best for their purposes, after it has been kept two or three years. But this is only owing to the *oil*'s being adulterated with spirit of wine, and usually containing too large a proportion of the spirit when first sent over, it becomes better for use when a part of that spirit has had time to evaporate in the keeping. It would be a better way for these curious works, to procure the *oil* pure, and then occasionally mix it with such a proportion of spirit of wine, as experience shews to be the most proper. Mem. Acad. Par. 1716.

SPIKENARD, in botany. See the article NARDUS.

Ointment of SPIKENARD. See NARDINUM *unguentum.*

SPIKES, or, as the seamen call them, SPEEKS, in a ship, are large long iron nails with flat heads. They are of divers lengths, some a foot, or two long, and some are jagged, so that they cannot be drawn out again. They are used to fasten the planks and timbers. They call also a kind of small fidd, which serves them to open and splice small ropes, a *marling spike.*

SPINA (*Cycl.*)—SPINA *bifida*, in anatomy, a parting of the *spinal* processes into two rows. The existence of such a case is doubted. See SPINE.

SPINA *burgi*, in botany, a name used by some authors for the *alaternus*, or ever-green privet, a garden shrub, the fruit of which is a mild astringent. *Park.* Theatr. p. 1445.

SPINA *ventosa*, is properly a species of corruption of the bones, which takes its rise in their internal parts, and by degrees enlarges the bone, and raises it into a tumor.

The antients were strangers to this name for this disorder, and called it *sideratio*, *gangræna*, or *cancer ossis*, and sometimes expressed it by the word *teredo*. Some among the French call it also an *exostosis*, though this is a term more properly denoting certain eminences, or preternatural acuminated excrescences in the bones, which happen after fracture, or other accident, and are some.imes attended with a caries.

The name of the disorder seems to have been borrowed from *spina*, a thorn, from the resemblance the eminences of the bone in this case bear to thorns, continually pricking the flesh, and producing the most grievous pains; and the epithet *ventosa* is added, because the tumor seems, to the touch, to be filled with air, though this is very rarely the case. This seems to have been the origin of the name *spina ventosa*, which some after-writers barbarously distorted into *spinæ ventositas*. When this disorder happens to children, Severinus, and many others, call it *pædarthrocaces*.

In the *spina ventosa* the caries, or erosion of the bone, is occasioned by a depravity of the contained fluids, and generally arises spontaneously, or without any external cause, and does not begin upon the surface of the bone, but between its lamellæ, or else in its internal cavity; from whence extending itself by degrees to the external parts, it at length either affects the whole bone, or a greater or smaller part of it, expanding itself to different widths, and rising to a tumor, which is sometimes hard, and without pain, and at others feels as if it were filled with wind, and is attended with a greater or lesser degree of pain, pricking and shooting, and at last grows red, and is attended with other bad symptoms, till the disordered bone being by degrees corroded, the common integuments, and other softer parts that lay over it, remaining at first entire, but at last partaking of the disorder, foul ulcers of a very terrible sort break out. When tumors of the bone are hard, and the soft parts about them not inflated, and are free from redness, inflammation, and pain, as is very frequently the case in ricketty disorders, the bad symptoms just described seldom come on. This is properly the pædarthrocaces, but the painful, red, inflated tumors happening equally to children, and to adults, are properly the *spina ventosa.*

It differs from a caries by being attended with a tumor, and from the rickets by its being accompanied with pain and erosion. It generally begins about the heads, or epiphyses of the larger bones, where they are most tender and spungy, and where the noxious matter may not only have sufficient room to lodge in the cellular substance, but where it will also meet with the least resistance in softening and expanding the parts. Sometimes, however, it also arises in the middle of the bones, between their lamellæ, especially in the tibia. The os frontis is also subject to disorders of this kind in venereal cases, and it is frequently situated in the bones of the face, neck and breast; though those of the arms, legs, fingers, carpus, meta-carpus, tarsus, and meta-tarsus, are more frequently the subjects of it.

Though this disorder usually arises from internal, yet it is sometimes found to be owing to external causes; especially in persons constitutionally addicted to a disorder of this kind, when the vessels between the lamellæ of the bone, or in the medulla itself, are by a blow, fall, or other external violence, injured, or torn, and their fluids extravasated, and by degrees putrefy, corrupt, and destroy the medulla, and soften the very substance of the bone, and corrode it; whence proceed pain, tumors, ulcers, and fistulas of the bone, and adjacent parts, and all the same train of mischiefs which attend these disorders, when begun spontaneously from internal causes.

The proximate cause of this disorder is a collection, or congestion, either of a viscid and thick, or of an acrimonious and corroding humor, or an inflammation arising in the medulla, or in the cellular substance of the bone, degenerating into an abscess, and forming matter, or ichor. As these stagnating fluids can find no discharge from the bones, especially from their cavities, they continue confined there till they putrefy, and become acrimonious, and corrode and destroy the neighbouring parts, converting them, particularly the medulla, into a kind of sanies; and at length they attack the bone and destroy it. The collection of viscid and pituitous humors, and the expansion of the bones, sometimes happens without pain, as in ricketty cases, but the erosion of the parts can never happen without the most acute pains.

When the internal parts of the bones only are affected by this disorder, the pain does not encrease upon external pressure; when the pain encreases upon external pressure, the external parts are brought into consent; and when this happens, the periosteum, and parts which surround it, with the substance of the bone and tunica cellularis, enlarge, from whence a sensation frequently arises, as if the parts were filled with air, or wind. But when the tumor is opened, either spontaneously, or by the knife, the bone, if it lies bare, is found full of small erosions, resembling a spunge or pumice-stone.

Of this terrible disorder there are properly three degrees: the first is, when the patient complains of a continual grievous pain in the bone, which seems to him to proceed from the marrow, and torments him so, that he can have no sleep, and all this while there is no external pain or tumor; in this case the disease is confined to the internal part of the bone. The second degree is when a tumor appears to be arisen on the surface of the bone, and is attended with external pain, more or less. The third degree is when, after the former symptoms, an ulcer is formed in the tumor, which discharges a fetid ichor, or purulent matter, smelling like rank butter or lard.

There are two methods of treating this disorder, one suited to the milder, the other to the more violent state of it, in which the bones, and the parts surrounding them, are entirely corroded and destroyed. In the milder stages, the acrimony of the blood must be endeavoured to be corrected by large draughts of the decoctions of the woods, with the China and sarsaparilla roots. The parts affected should also be fumigated with the steam of decoctions of aromatic herbs, and twice a day, in the intermediate times, the part may be rubbed over with a mercurial ointment, and afterwards covered with the common mercurial plaster. Mercurial medicines should also be given internally, according to the strength of the patient, and sometimes a salivation is necessary.

Mercurial remedies seem indeed so peculiarly appropriated to this case, that nothing is to be done without them; and it hence looks very suspicious, that something venereal is always in the case, or else that the disorder is of itself very much akin to that disease. By diligently pursuing this method for some weeks, the first and second stages of this disease may be cured even where there are bony tumors formed; and the tumors may either be reduced, or at least brought to that state, that they will remain as they are without farther encrease, or without pain, or any farther inconveniency.

But when these tumors are so far advanced, as to be out of the reach of the remedies, the pain and tumors encreasing, and abscesses forming; as there is great reason to fear the

the entire destruction of the bone, if the abscess does not burst of itself, the surgeon should not stay for its maturation, but lay the bone bare in the lowest, or in the most painful part. When the abscess is already burst, if the opening be too small, it must be enlarged with a knife, or if the patient too much dreads the knife, the caustic may supply its place; and after this several small holes must be made in the bone with a small piercer, perforating it into the medulla, to give way for the discharge of the confined matter; and when these small holes are not sufficient, a larger must be made by the trepan, if the bone will admit it: this will not only make more way for the discharge of the matter, but will also give room for the proper application of remedies better than any other method.

While this is under cure, the patient must use internally the decoctions of the woods, and mild mercurial, and antimonial medicines; and externally the wound must be treated with cleansing, and balsamic remedies, such as decoctions of agrimony, sanicle, St. John's wort, or birthwort, and essence of myrrh and aloes. These should be injected warm with a syringe twice every day, as may also a solution of mercurius dulcis made in plantane-water, or in lime-water. Honey of roses should be added in a small quantity to either of the decoctions, used as essences; and after the use of them, the wound should be dressed with the before-mentioned essences, or with those of mastich or amber, spread upon lint, and covered with a mercurial, or other plaster: this method is to be continued till the parts are healed. The actual cautery is sometimes necessary to root out the disorder, especially when it is only between the lamellæ of the bone, for in other cases there is no getting to the bottom with it.

But when all these methods are unsuccessful, and the part is already too much corroded and destroyed, there is no hope of saving it, nor indeed of saving the life of the patient, by any other means than the taking off the limb. When the disorder is situated, however, in some small bone, as on the carpus, tarsus, meta-carpus, or meta-tarsus, or fingers, it will not always be necessary to take off the whole limb, that is to say, the finger, foot, or hand, but it will frequently suffice to remove the corrupted bone alone. In larger bones, where the whole bone is not affected, but only a part of its external surface is disordered by either a caries, or *spina ventosa*, the whole limb is by no means to be taken off, but the diseased part of the bone only removed: but when a large bone, as the os humeri, tibia, or femur, or an entire joint of the arm, knee, or foot, is diseased, there is no remedy but amputating it in the sound parts just above. *Heister's* Surgery, p. 264.

Dr. Schlichting affirms, that the *spina ventosa* may be cured by rubbing the tumor twice a day with ung. Neapolit. preventing salivation by gentle cathartics. Phil. Trans. N° 466. sect. 10.

It appears likewise, from a case related in the Philosophical Transactions, that amputation of the limb is not always necessary. Vid. Phil. Trans. N° 480.

SPINACHIA, *spinach*, in botany, the name of a genus of plants, the characters of which are these. The flowers are of the apetalous kind, consisting only of a number of stamina. These flowers are also barren, and the embryo seeds are found on such parts, or different plants of *spinach*, as have no flowers. These finally become seeds of a turbinated form, and are contained either in a capsule of the same figure, or else in a cornuted or angular one.

The species of *spinach*, enumerated by Mr. Tournefort, are these. 1. The common *spinach* with prickly seed-vessels. 2. The common barren *spinach*. 3. The procumbent Cretic *spinach* with echinated capsules. And 4. the common *spinach* with smooth capsules. *Tourn.* Inst. p. 533.

The common *spinach*, intended for winter use, should be sown on an open spot of ground in the latter end of July, observing to do it, if possible, when the weather is rainy. When the young plants are come up, the weeds must be destroyed, and the plants left at about five inches asunder. The ground being kept clear of weeds, the *spinach* will be fit for use in October. The way of gathering it to advantage, is only to take off the longest leaves, leaving those in the center to grow bigger; and at this rate a bed of *spinach* will furnish the table for the whole winter, till the *spinach* sown in spring is become fit for use, which is common in April. *Miller's* Gard. Dict.

SPINACHIA, in zoology, a name given by some authors to our common stickleback, or barnstickle, more usually known among writers by the names *pugnitius*, or *aculeatus pisciculus*. *Gesner*, de Aquatil. See the article PUGNITIUS.

SPINALIS (*Cycl.*)—SPINALIS *cervicis*, in anatomy, a name given by Albinus to a muscle of the neck, called by Fallopius the *tertium par musculorum dorsi*, and by Cowper and Morgagni *spinalis colli*.

This is the muscle which the French anatomists call *les vertebraux externes du demi-epineux, ou le transversaire epineux du col.* See TRANSVERSALIS, &c.

SPINALES *colli minores*, muscles lying between the six *spinal* apophyses of the neck, and between the last of the neck and first of the back; being inserted in these apophyses by both extremities on one side of the posterior cervical ligament, which parts them from those of the other side. They are likewise termed *interspinales*. Vid. *Winslow's* Anat. p. 244.

SPINALIS *dorsi*, in anatomy, a name given by Albinus to a muscle of the back, figured by Eustachius Tab. 37. and called by Fallopius *quintiparis dorsi musculorum pars implantata in spinas vertebrarum thoracis*.

Others, as Spigelius, have called it a part of the *semispinatus*, and others a part of the *longissimus dorsi*. The French have named it *le grand epineux de dos*. See the articles SEMISPINATUS and LONGISSIMUS *dorsi*.

SPINALIS *dorsi major*, a pretty long and slender muscle, lying upon the lateral part of the extremities of the *spinal* apophyses of the back. It is composed of several muscular fasciculi of different lengths, which crossing each other, are inserted laterally by small tendons in the *spinal* apophyses from the second, third, or fourth vertebræ of the back; and sometimes, though seldom, from the last of the neck, or first of the back, all the way to the first or second vertebra of the loins, with several irregular decussations, which vary in different subjects. The longest fasciculi are all a little incurvated, and the whole muscle terminates in points at its ends, but is considerably broad in the middle. It communicates by some fibres with the longissimus dorsi, and *semispinalis*, and sends off fasciculi to several transverse apophyses of the back, from the fourth to the eleventh. It is called by some *semispinalis*, but very improperly. *Winslow's* Anatomy, p. 247.

SPINALES *dorsi minores*. These muscles are of two kinds; some go laterally from the extremity of one *spinal* apophysis to another, being often mixed with the short fasciculi of the *spinalis* major; the rest lie directly between the extremities of two neighbouring *spinal* apophyses, being separated from those on the other side by the *spinal* ligament. These are smaller and thinner than those of the neck, and are properly enough termed *interspinales*. *Winslow's* Anatomy, p. 248.

SPINALES *et transversales lumborum*. There are some fasciculi which run up from the superior false *spines* of the os sacrum to the lower *spinal* apophyses of the loins, which may be looked upon as so many *spinales lumborum majores*; and there are also some *spinales lumborum minores* between the *spinal* apophyses of the loins, and *transversales minores* between the transverse apophyses, which are sometimes of a considerable breadth. *Winslow's* Anatomy, p. 249.

SPINARELLA, in ichthyology, a name given by Bellonius, and some other authors, to the little fish called by us the *lesser stickleback*, and distinguished by Artedi by the name of the *gasterosteus* with ten spines on the back. See the article GASTEROSTEUS.

The size is an uncertain mark, but this number of the spines wholly determines the species, the common *gasterosteus*, or stickleback, having only three.

SPINATUS, in anatomy, a name given by Riolanus, and others, to a muscle of the neck, called by Albinus *spinalis colli*, and by Winslow, and the other French writers, *les vertebraux externes du demi-epineux, ou transversaire epineux du col.* See the articles SPINALIS and TRANSVERSALIS.

SPINDLE (*Cycl.*)—SPINDLE, in mining, is a piece of wood fastened into either stow-blade. *Houghton's* Compleat Miner in the Explan. of the Terms. See the article STOWS.

These stows give a miner, or any other person that owns them, as good a right to a meer or meers of ground, (so that every meer have a pair of stows set on them) as a deed of conveyance doth to any purchaser. *Houghton*, ibid.

SPINDLE, in ship-building, a part of the capstan. See the article CAPSTAN, *Cycl.* and *Suppl.*

SPINE (*Cycl.*)—This takes in all that order of bones which follow one another without interruption, from the os occipitis downward along the posterior part of the trunk.

It represents a very compound folding pillar, round on the foreside, and on the backside stuck full of prickles or points, representing so many *spines*. It has a canal in the middle through its whole length, into which a great number of holes open on each side. When it is viewed directly on the foreside or backside, it appears strait, and to be made up of different portions of pyramids, in a contrary situation to one another; but viewed sideways, it presents several different curvatures. The pieces which compose the *spine* are of two kinds, one simple, the other compound; the single pieces are generally twenty four in number, called by the name of *vertebræ*; the compound pieces are two, the os sacrum and os coccygis. The single species are also called *true vertebræ*, to distinguish them from the portions which compose the other two, which are called *false vertebræ*. The true vertebræ are divided into three classes, *viz.* seven of the neck, twelve of the back, and five of the loins; and to these are given the names *cervical*, *dorsal*, and *lumbar*. *Winslow's* Anatomy, p. 53.

This bone, when felt through the integuments, seems sometimes divided, and has given rise to the notion of a *spina bifida*, or bifurcation of the *spine*. But some doubt of the existence

exiftence of fuch a cafe, as a perfect *fpina bifida*, fuppofes the very canal and *fpinal* marrow to divide into two branches, and the *fpinal* proceffes to divaricate into two rows. We have a cafe in the Philofophical Tranfactions, where the *fpinal* marrow of an infant was found bare, without any bony covering, and which was taken for a *fpina bifida*. See Phil. Tranf. N° 472. fect. 2. and N° 366. p. 98.

See, in the Mem. de l'Acad. Royale des Sciences anno 1730, fome curious obfervations, by Mr. Winflow, on the motions of the *fpine*.

Cartilages of the SPINE. The cartilages of all the vertebræ in general are of two kinds, one proper to each vertebra, the other common to two vertebræ which lie next one another; the firft may be termed the *cartilages of articulation*, the latter the *cartilages of fymphyfis*.

The proper articular cartilages of each vertebra of the whole *fpine* are thofe four which cover the furfaces of the four fmall articular apophyfes. In the natural ftate they are very white and fmooth, and much thicker than in the dried bones. Their circumference is the fame with that of the articulated fides of the apophyfes, except in thofe places where there are fmall fuperficial notches. The vertebræ of the back, befide the four cartilages of their fmall apophyfes, have others which do not belong to their articulations with one another, *viz.* thofe which cover the lateral foffulæ in the bodies of thefe vertebræ, and the foffulæ in their tranfverfe apophyfes, by both of which they are articulated with the ribs.

The cartilages of the fymphyfis lie between the bodies of the vertebræ, one of them being contained between, and clofely joined to the lower furface of one vertebra, and to the upper furface of the next under it; the breadth and circumference of thefe anfwer exactly to thofe of the furfaces between which they are contained, but their height, or thicknefs, is different in each clafs of the vertebræ. In the vertebræ of the loins they are, according to the ftature of the fubject, a quarter or a third of an inch thick, in thofe of the neck they are not fo thick, and thinneft of all in thofe of the back. Neither are they of equal thicknefs in all their parts, thofe of the neck and loins appear to be thickeft on the forefide, and thofe of the back rather thickeft on the contrary part; but thefe differences are moft remarkable in the vertebræ that lie near the middle of each clafs.

The internal ftructure of thefe cartilages is different from that of all the other cartilages of the body, and indeed they refemble the reft in nothing but in whitenefs and in elafticity. When we view their circumferences only, they appear to be one uniform mafs like the reft, but when divided by an incifion, parallel to the furface of the vertebræ, we fee that they are made up of a great number of concentric cartilaginous rings, contained within each other, with a fmall fpace left between them. Thefe are clofeft and thinneft near the center, and about the middle feem to degenerate into another fofter kind of fubftance. Thefe rings do not form an entire circumference, being turned inward on the backfide, anfwerably to the pofterior flope in the body of each vertebra. They lie horizontally, one edge being fixed to the lower fide of one vertebra, and the other to the upper fide of the vertebra next below the former.

The interftices between the rings are filled with a mucilaginous fubftance, lefs fluid than that of the joints, and their breadth, or heighth, is proportionable to the diftance of the vertebræ between which they lie.

Each cartilaginous lamina taken feparately is very pliable, according to its length, but taken all together they are not fo eafily bent, partly becaufe of their circular figure, and partly becaufe of their proximity and multiplicity. They yield, however, in the inflexions of the *fpine*, and without any inflexion to the weight of the head and upper extremities; but this is done by very fmall degrees, and moft of all, when the upper part of the body is loaded with any foreign weight. After thefe compreffions they reftore themfelves, merely by being freed from the preffure; fo that a man is really taller after lying fome time, than after he has carried a burthen for a great while. Thefe fingular obfervations of the different heights of the fame perfon, at different times, which were firft made in England, and afterwards confirmed at Paris by Mr. Morand, are moft naturally and eafily accounted for, merely by the different ftate of the intervertebral cartilages.

The intervertebral cartilages of the neck lying, for the moft part, between the convex fide of one vertebra, and the concave fide of another, are of a greater extent, in proportion to the fize of thofe vertebræ, than thofe of the back and loins. The os facrum has no cartilage, except that between the upper fide of the firft falfe vertebra, and the laft vertebra of the loins; and thofe by which it is connected to the offa innominata, already defcribed as the cartilages of that bone. The cartilages, which join the different portions of the os coccygis, are preferved in fome fubjects to a very great age, but in others they very foon become entirely bony. *Winflow*'s Anatomy, p. 145.

Ligaments of the SPINE. The vertebræ are ftrongly connected to each other by three kinds of ligaments. Each vertebra is connected to thofe above and below it by a great number of very fhort and ftrong ligaments, which crofs each other obliquely, and are fixed round the edges of the body of each vertebra. Thefe crucial ligaments cover the circumference of the intervertebral cartilages, and adhere clofely to them.

The bodies of all the vertebræ, from the fecond of the neck to the os facrum, are covered by ligamentary half vaginæ on the convex fide, in which thefe vaginæ are fixed, furrounding all the crucial ligaments, and made up of ligamentary filaments partly oblique, but for the moft part longitudinal. All the vertebræ are likewife ftrongly connected by a ligamentary tube, which lines the inner furface of the medullary canal from the occipital hole to the os facrum; it reprefents a long flexible funnel, its cavity at the upper part being equal to that of the occipital foramen, and ending in a point at the os facrum. The firft vertebra is fixed to the os occipitis befide this, by a diftinct and very ftrong ligamentary covering; the fecond has two ligaments peculiar to it, one which connects the apophyfis dentiformis to the os occipitis, and another tranfverfe, which confines this apophyfis within the anterior portion of the cavity of the firft vertebra. The firft may be called the occipital, and the fecond the tranfverfe ligament of the odontoide apophyfis. Along the whole bony canal of the *fpine*, between the bafes of each *fpinal* apophyfis, lies a flat and very elaftic ligament, of a yellowifh colour, which fills up the pofterior great notches of the vertebræ, adhering to their edges, and to the neighbouring portions of the inner ligamentary tube.

Between the extremities, or apices of the *fpinal* apophyfes, are fmall ligamentary ropes, which go from one *fpine* to the next, which are all really double, though they appear fo only in the neck, being there fixed feparately to the forked extremities of the *fpines*. Between all the *fpinal* apophyfes, from their apices to the middle of their bafes, lies a ligamentary membrane, going between each two; and there is a ligament of a like kind between the two tranfverfe apophyfes in all.

The articular ligaments of the *fpina* dorfi are thofe which tie the glenoide cavities of the firft vertebra to the condyles of the os occipitis; thofe that join the cartilaginous furface of the apophyfis dentiformis to the anterior cavity of the firft vertebra, and thofe by which all the oblique, or articular apophyfes, are connected together. Thefe are all fmall, fhort, and ftrong. The vertebral ligaments of the ribs, or thofe which connect the ribs to the vertebræ, are of the fame kind, and are inferted round the cartilaginous foffulæ in the body, and apophyfes of each vertebra. Befide all thefe ligaments of the *fpine*, there is one which goes in form of a membrane from the os occipitis, all the way to the laft two vertebræ of the neck: this is a true intermufcular ligament, and may be properly called the *ligamentum cervicale pofterius*. There are alfo two lateral ligaments of the fame kind, fixed to the tranfverfe apophyfes of the vertebræ of the neck. *Winflow*'s Anatomy, p. 147.

SPINES *of echini*, in natural hiftory. Thefe in their foffile ftate make a great appearance in the cabinets of the curious, and in the works of the learned, and are of an almoft infinite variety of kinds; and many of them are of the fame figures and dimenfions with thofe of the echini now living in our own and other feas, and well known to us. But hefide thefe there are an almoft infinite variety of others, which though allowed on all hands to be truly *fpines* of fome echini or other, yet evidently differ from thofe of all the known recent fifh of that name, and have certainly belonged to fpecies of it which we have not yet the leaft knowledge of. Thefe, however different in fhape from one another, yet all agree in their texture and conftituent matter, both with one another, and with the foffile remains that fupply the places of the fhells of the other fpecies fo common in our chalk-pits, all being compofed of a plated, or tabulated fpar. Both thefe fhells and the *fpines*, though they retain every outer lineament of the bodies they owe their form to, yet have they nothing of their interior texture, nor any the leaft refemblance of it, but are compofed of plates fet edgewife, or aflant, in the fhells, and in the *fpines* always obliquely to the axis of the body; fo that all the foffile *fpines of echini* break regularly in an oblique direction, and always fhew on each part a perfectly fmooth and gloffy flanting furface.

Of the foffile *fpines of echini* fome are long and flender, tapering from a broader bafis to a fine point, and fometimes from a thick part, at or near the middle, to an obtufe point at each end: thefe are ufually ftriated, ridged, or furrowed, and often elegantly granulated, though fometimes they are fmooth. Thefe moft refemble the *fpines* of the more common fpecies of recent or living echini we are acquainted with; others of them are of very different and very ftrange figures; fome are of the fame length with the common long ones, but are very flat, and are ridged more or lefs high, or covered with tubercles of different fhapes; others are ragged, and varioufly jagged, and knotted like a rough branch

branch of fir ſtript of its leaves, or that ſort of fucus called the *ſea ragged ſtaff*. Another very common kind in ſome parts of the world, eſpecially in Syria, but leſs frequent with us, is the body called by authors *lapis judaicus*: theſe are ſuppoſed, in ſome ſort, to reſemble an olive, ſwelling from a ſhort ſtalk to a large thick and ſhort body of an oval figure, and marked very elegantly with longitudinal furrows, and in the different ſpecies with very differently ſhaped tubercles. Of this ſhape there are alſo ſome perfectly ſmooth.

We have alſo with us great numbers of a kind approaching to theſe, but having longer ſtalks and ſmaller bodies, and theſe we meet with of all ſizes, from three inches in length down to the bigneſs of a barley-corn; and there are at times found ſome of all the intermediate figures, between theſe tumid ones and the long and ſlender ſort.

We have numbers alſo of various lengths, and variouſly ſurrounded with granulæ of a ſhape nearly cylindric, and beſide the bodies themſelves, we meet with impreſſions of all the kinds on our flints in gravel-pits. The *ſpines* themſelves are uſually bedded in the ſtrata of chalk, though ſometimes they are found in the ſtone-quarries, and ſometimes, but that moſt rarely, bedded in clay, or looſe among gravel. *Hill's* Hiſt. of Foſſ. p. 652.

SPINNING (*Cycl.*)—The art of *ſpinning*, which nature has given to many animals of different kinds for their preſervation and other purpoſes, is not confined to the inhabitants of the earth or air alone, but is even extended to thoſe of the ſea. Mr. Reaumur has ſhewn, by a ſeries of curious experiments, that the common muſcle, and ſome other ſhell-fiſh of the ſea, poſſeſs it in a great degree of perfection. See the article MUSCLE.

But he obſerves, that though the workmanſhip is the ſame, the manner of producing it is very different. Spiders, caterpillars, and the like, make threads of any length that they pleaſe, by making the viſcous liquor, of which they are formed, paſs through a fine perforation in the organ appointed for this *ſpinning*: but the way in which the muſcles form their threads is very different, as the former reſembles the work of the wire-drawer, ſo this does that of the founder, who caſts metals in a mould. The canal of the organ, deſtined for the muſcle's *ſpinning*, which from its ſhape is commonly called its tongue, is the mould in which its thread is caſt, and gives it its determinate length. Mem. Acad. Par. 1711.

SPINOSA, in zoology, the name by which the Italians call the porcupine. See the article HISTRIX.

SPINOSE-*leaf*, among botaniſts. See the article LEAF.

SPINOSI *piſces*, in zoology, ſuch fiſhes as have ſome of the rays of their backfins running out into thorns or prickles, as the pearch, &c. *Willughby*, Hiſt. Piſc. p. 271.

SPINOZISM (*Cycl.*)—We have an examination of *Spinoziſm*, and of Mr. Bayle's objections againſt this ſyſtem, by Monſ. de Jariges, in the Mem. de l'Acad. de Berlin, Tom. I. p. 121. and Tom. II. p. 295. Wolfius has alſo given a refutation of *Spinoza*, in his Theol. Nat. Part 2.

SPINTHER, among the Romans, a kind of bracelet which the women, in the firſt ages of Rome, uſed to wear on the upper part of their left arm.

SPINUS, in the natural hiſtory of the antients, the name of a foſſile body of a very remarkable quality; for according to the accounts of Theophraſtus, and other authors of the greateſt credit, if broke to pieces, and thrown in an heap expoſed to the ſun, it took fire and burnt, and that the more, if moiſtened or ſprinkled with water.

It ſeems to have been a ſubſtance nearly allied to what they called the *lapis thracius*, but with this remarkable quality, both of them ſeem to have been of the claſs of the harder bitumens, and are wholly unknown to us. Some late writers have imagined, that the common black ſlate-ſtone, ſo frequent with us in the coal-pits, was the ſubſtance called by Theophraſtus, and the antients, by this name, but it has none of the qualities attributed to the *ſpinus*. *Hill's* Theophraſtus, p. 35.

SPINUS, in zoology, the name of a ſmall bird, called by ſome *ligurinus*, and in Engliſh the *ſiſkin*. Its head is black, and its neck and back green. The neck, however, has ſome ſlight admixture of a blackiſh tinge, and the roots of the backfeathers have alſo ſome blackiſhneſs. Its rump is of a greeniſh yellow, as are alſo its breaſt and throat. Its belly is white, and its tail is yellow underneath, with ſome browniſh ſpots. The female is paler coloured than the male, and its throat, and its ſides, under the wings, are whitiſh, with ſtreaks of brown. It is common in Germany and England, and is kept in cages for its ſinging. In winter theſe birds fly in large flocks. *Ray's* Ornitholog. p. 192.

SPIPOLA, in zoology, the name of a ſmall bird of the lark kind, of which there are, according to Aldrovand, three ſpecies, ſuſpected by Mr. Ray to be only varieties of the *ſpipoletta*, or *tordino* of the Venetians. *Aldrovand.* de Avib. lib. 17. cap. 26. See the next article.

SPIPOLETTA, in zoology, the name of a ſmall bird of the lark kind, called *tordino* by the Venetians, and ſeeming to be the *ſtopparola*, as alſo the *griſola*, and *ſpipola* of Aldrovandus. It is ſmaller than the common lark; its head, neck, ſhoulders, and back, are of a greyiſh colour, with an admixture of green; its breaſt and belly white, and its throat ſpotted. The female differs from the male, in that her belly is yellow. The wing-feathers are of a duſky brown, with whitiſh or yellowiſh edges. Its tail is moderately long, and part of the feathers are ſnow-white, the reſt brown or blackiſh. The length of the heel diſtinguiſhes this bird from all others, except the lark kind, and it differs from all the ſpecies of larks in the colour of its beak and legs, which are black. It is common in the markets of Venice and other places. *Ray's* Ornitholog. p. 153.

SPIRÆA, in botany, the name of a genus of plants, the characters of which are theſe. The flower is of the roſaceous kind, being compoſed of ſeveral petals arranged in a circular form. The piſtil ariſes from the cup, and finally becomes a fruit compoſed of ſeveral ſmall pods, containing oblong ſeeds.

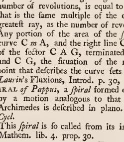
The ſpecies of *ſpiræa*, enumerated by Mr. Tournefort, are theſe. 1. The willow-leaved *ſpiræa*. 2. The opulus-leaved *ſpiræa*. 3. The *ſpiræa* with hypericum leaves, not indented. And 4. the Spaniſh *ſpiræa* with crenated leaves, reſembling thoſe of the hypericum. *Tourn.* Inſt. p. 618.

The ſeveral ſpecies of this plant are very common in our gardens, and make a very beautiful figure. They are propagated either by ſuckers, which they produce in great abundance, or by laying down the tender branches of the old plants. When they have taken root, they ſhould be removed into the nurſery for two or three years, and will then be fit for tranſplanting in the places where they are to remain. *Miller's* Gard. Dict.

SPIRAL (*Cycl.*)—As a curve may approach continually to a right line, or to another curve, while they are both produced, and yet never meet it, ſo a *ſpiral* line may approach continually to a certain point, and not reach it in any number of revolutions, how great ſoever, that can be aſſigned. This happens in the logarithmic, or logiſtic *ſpiral*, and in ſeveral others. See *Mac Laurin's* Fluxions, Book 1. p. 283. ſeq.

Some of theſe *ſpirals*, after having made an infinite number of revolutions, is ſaid, in the modern ſtile, to reach that certain point, and yet the length of the *ſpiral* may be finite, or equal to an aſſignable line. Propoſitions, expreſſed in this manner, ſeem the moſt myſterious of paradoxes; but the wonder diſappears, when we know it amounts to no more than that a line may continually increaſe, and yet the increments acquired may decreaſe in ſuch a manner, that it ſhall never amount to a given line.

SPIRAL *of Archimedes*. The *ſpiral* area CABDE, is equal to one third part of the circle, deſcribed with the radius CE.

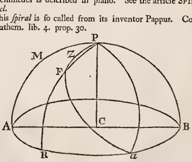


In like manner, the whole *ſpiral* area, generated by the ray drawn from the point C to the curve, when it makes two revolutions, is the third part of a ſpace double of the circle deſcribed with the radius 2 CE; and the whole area, generated by the ray from the beginning of the motion, till after any number of revolutions, is equal to the third part of a ſpace that is the ſame multiple of the circle deſcribed with the greateſt ray, as the number of revolutions is of unit.

Any portion of the area of the *ſpiral*, terminated by the curve C *m* A, and the right line C A, is equal to one third of the ſector C A G, terminated by the right line C A, and C G, the ſituation of the revolving ray, when the point that deſcribes the curve ſets out from C. See *Mac Laurin's* Fluxions, Introd. p. 30, 31.

SPIRAL *of Pappus*, a *ſpiral* formed on the ſurface of a ſphere, by a motion analogous to that by which the *ſpiral* of Archimedes is deſcribed in plano. See the article SPIRAL, *Cycl.*

This *ſpiral* is ſo called from its inventor Pappus. Collect. Mathem. lib. 4. prop. 30.



Thus, if C be the center of the ſphere, ARBA a great circle,

circle, P its pole; and while the quadrant P M A revolves about the pole P with an uniform motion, if a point proceeding from P move with a given velocity along the quadrant, it will trace upon the spherical surface the *spiral* P F *a*.

Now if we suppose the quadrant P M A to make a compleat revolution in the same time that the point, which traces the *spiral* on the surface of the sphere, describes the quadrant, which is the case considered by Pappus; then the portion of the spherical surface, terminated by the whole *spiral*, the circle A R B A, and the quadrant P M A, will be equal to the square of A B. In any other case, the area P M A *a* F P is to the square of the diameter A B, in the same proportion as the arch A *a* is to the whole circumference A R B A. And this area is always to the spherical triangle P A *a*, as the inscribed square is to the circle. See *Mac Laurin*'s Fluxions, Introd. p. 31—33.

The portion of the spherical surface, terminated by the quadrant P M A, the arches A R, F R, and the *spiral* P Z F, admits of a perfect quadrature, when the ratio of the arch A *a* to the whole circumference can be assigned. See *Mac Laurin*, ibid. p. 33.

SPIRINCHUS, a name by which some authors have called the smelt. *Willughby*, Hist. Pisc. p. 202. See the article EPERLANUS.

SPIRITS (*Cycl.*)—*Brandy* SPIRITS. *Brandy* differs from wine *spirit*, in that the former is drawn from the poorer and thinner sorts of wines, the latter from the richer and fuller bodied wines. *Shaw*'s Ess. on Distil. p. 128.

Brandy also differs from *spirit* of wine, as the former is only what they call proof high, or half pure *spirit*, half phlegm; whereas *spirit* of wine is raised higher, or carried by rectification to a further degree of purity.

Brandy also differs from strong waters, as the latter is a compound, whereof the former, or pure *spirit* of wine, is only one ingredient.

The Portugueze are lately come into the way of making *brandy* [b]. The Greek *brandies* are the worst, though made of the best wines [c].—[[b] Atlas Marit. p. 154. [c] *Tournf.* Voyag. du Levant, Tom. I. let. 2. p. 35.]

The Spanish *brandies* are much coarser than the French, though sometimes made to pass for them in Holland, and other places of great traffic [d]. Some prefer Rhenish *brandy* to that of France; and in Holland particularly, it sells for double the price. It is indeed a fine *spirit*, but the English know little of it farther, than that a dash thereof serves to fill up a cask of French [e]. Some tell us of frozen *brandy*, of which Mr. Boyle gives an instance in Russia; but it is only the watery part that is capable of congelation. All the effect of the most intense cold on *brandy*, is to make a separation between its *spirit* and phlegm; the former retires to the center in form of pure alcohol, while the latter invests it with a circumference of ice [f].—[[d] *Shaw*'s Ess. on Distil. sect. 5. p. 139. [e] Id. ibid. p. 141, seq. [f] *Boyle*'s Works Abr. Tom. I. p. 594.]

Brandies always differ, according to the different species and growth of the grapes. We have various kinds of French *spirits*, having each their particular flavours, by which the connoiseurs readily distinguish one sort from another; though the vulgar call them all indiscriminately by the name of *French brandy*. An ordinary judgment may easily distinguish Languedoc *brandy* from that of the isles of St. Martin and Oleron; or Bourdeaux from Cognac. Nor would the similitude between the several species of French *brandies* be so great as it is found, but that only the weakest and lowest flavoured wines are distilled for this purpose; or such as are unfit for other uses. When out of curiosity, or good husbandry, the French distil the bottoms, or refuse parcels of the grosser bodied and fuller tasted wines, the *brandy* got from them is what we in England rather call a wine *spirit*, than a *brandy*. Every kind of grape, as it affords a wine, so does it also a *brandy* of its own peculiar flavour. *Shaw*'s Ess. on Distil. sect. 5. p. 130, seq.

The too free and frequent use of *brandy* is attended with ill effects, as it attenuates the body, and impairs the strength, and stupifies the brain. In persons who have died hereof, the blood has been found thick and coagulated; the pancreas dried; the liver schirrous, and almost petrified; the glands tumefied beyond their natural bulk [g], *&c.* But what shall we say to the Parisian woman, who was burnt to ashes with a fire only kindled from the *brandy* in her body [h]? Conringius even attributes the degeneracy of the modern from the antient Germans, to the prevelancy of drinking this liquor [i].—[[g] Hist. Acad. Scienc. Anno 1706. p. 29. *Barth.* Act. Med. Tom. V. Obs. 118. p. 313. [h] Philos. Trans. N° 97. p. 6138. *Barth.* l. c. Tom. I. Obs. 118. p. 211. [i] *Conring.* de Habit. Corp. Germ. p. 99, seq.]

In the hot climates of America, they are said to make clysters of *brandy*. A person who had experienced the use of one of these fiery enemata, made of a pint of *brandy*, assures us, it not only made him dead drunk, but raving mad. Phil. Trans. N° 37. p. 721.

Brandy is also applied, in a less proper sense, to all *spirituous* inflammable liquors, drawn from vegetables by distillation. In which sense *brandy* includes all ardent, or inflammable *spirits*, used in the way of beverage. Dr. Shaw adds a further limitation to *brandy spirits*, viz. that they be proof high, or consist of equal quantities of water and alcohol. On which footing, *spirits*, either above or below proof, do not come under the appellation of *brandies* [k]. But in the popular use this distinction is not kept to.—[[k] *Shaw*'s Ess. on Distil. sect. 5. p. 130.]

Arrac, rum, malt and melasses *spirits*, in this sense, are *brandies*, though under another denomination.

In the island of Andros they make brandies from the fruits of the arbutus and mulberry trees. Atlas Marit. p. 176.

A patent was some time ago obtained for making *brandy* from carrots and parsneps; the latter of which is said to have nearly resembled French *brandy* [l]. Of late we meet with frequent advertisements of raisin-*brandy*, which, if really made of that fruit, is nearest akin to wine-*brandy*.—[[l] *Hought.* Collect. Tom. II. p. 382. 461.]

Apple, or cider-*brandy*, is also praised by some.

Cider is found to yield an eighth part of good *spirits*, and if close kept a year or two in a cool place, much more. Dict. Rust. Tom. I. in voc.

Brandy is also used to denote certain compound liquors, whereof *brandies* are the basis.

Such are raspberry-*brandy*, cherry-*brandy*, gooseberry-*brandy*, &c.

Cherry-*brandy* is usually made with black cherries, by filling a bottle half full with them, and adding *brandy* thereto till the bottle be full; this being shaken from time to time, within a month will be ready to drink.

If the like quantity of gooseberries, instead of cherries, be put in, it makes a good *brandy*. To dulcify it, and give it a fine flavour, they also put in sugar with raspberries. Dict. Rust. Tom. I. in voc. *cherry-brandy*.

The French method of distilling *brandies* is the same with that practised by our distillers, in working from wash or wines; only that the former throws a little of the natural lee into the still along with the wine, which gives the *spirit* a flavour, on which a great part of its merit depends. *Shaw*, lib. cit. p. 132.

When *brandies* prove foul, feedy, or retain the taste of certain weeds apt to grow among the vines, they draw them over again, in order to cleanse them of that adventitious flavour: in which operation they leave out the faints, or rather change the receiver, as soon as the stream begins to run proof. Then mixing together all that run off before, they call it *trois cinque*, that is, *brandy* consisting of five parts alcohol, and three of flegm; beyond which the French *bruleurs*, or common distillers, rarely go.

The yearly export of *brandies* from France is said to amount to 25000 tuns; an article of itself sufficient to enrich a moderate country [m]. While the duty on French *brandy* continued at 9 *l.* the tun, the English alone took 10 or 11000 tuns off their hands [n]; but now that the duty is raised to 52 *l.* the tun, the importation is greatly reduced, to the advantage of the English Distillery, except that smuggling still intervenes.—[[m] Atlas Marit. p. 146. [n] Compl. Engl. Trad. Tom. II. p. 89. Atlas Marit. p. 107. *Hought.* Collect. Tom. II. N° 387. p. 470.]

Divers reasons may be alledged for the great fecundity of *brandies* in France. All those poor grapes, which prove unfit for wine, are usually first gathered, pressed, and their juice fermented, and directly distilled: this rids their hands of their poor wines at once, and leaves their casks empty for the reception of better. It is a rule with them to distil no wines that will fetch any price as wines, for in this state the profit on them is vastly greater, than when reduced to *brandies*. This large stock of small wines, wherewith they are almost over-run in France, shews one great reason of their making such vast quantities of *brandy*, more than other countries, which lie warmer and better for grapes. But this is not the only fund of their *brandies*; for all the wine that pricks, or turns eager upon their hands, is also condemned to the still; and, in short, all that they can neither export, nor consume at home, which amounts to a large quantity, since much of the wine, laid in for their family provision, is so poor, as not to keep the spending. *Shaw*'s Ess. on Distil. sect. 5. p. 131, seq.

The colour of their *brandies* is acquired from the cask, and the length of time they usually lie therein, which is sometimes twelve or eighteen months, and often two or three years; during which, it is no wonder if they acquire a yellow or brownish cast. Their lying thus long, as it were, in a state of slow digestion, wonderfully takes off from that hot, acrid, and foul taste, peculiar to all *spirits*, or *brandies*, newly distilled; and gives them a coolness and a softness, not easily introduced by art. And on these properties are founded several methods of trying their goodness, or discovering whether they are debased or adulterated by the admixture of coarser *spirits*. Phil. Trans. N° 391. p. 398, seq. *Shaw*'s Ess. on Distil. sect. 5. p. 134.

Brandies are rarely adulterated in France, where they have no cheaper *spirits* to debase them withal; and the like holds, in great measure, in favour of the Dutch, though otherwise

wife fufpected to be great adulterators. The chief temptations for adulterating are in England, where the duties are high, and where there are various kinds of *fpirits* in plenty to mix with them, as malt, melaffes, cyder, and fugar *fpirits*, with all which they are often fophifticated, and fo dextroufly, as frequently to efcape all the ways of detection.

Rules for diftilling brandy SPIRITS. *Brandy*, whether made from wine, malt, fugar, or whatever elfe, is a compound confifting of four different parts, which are inflammable *fpirit*, effential oil, acid and water.

As thefe feveral parts do not differ greatly in their fpecific gravity, or degree of volatility, a ftrong tumultuary boiling heat will drive them all over promifcuoufly together. As at the beginning of the operation there ufually arifes more totally inflammable *fpirit* than water, fo after fome time the ftream contains more water than *fpirit*. This gives the foundation for what the diftillers call *low-wines*, *proof-fpirits*, and *faints*.

The *low-wines* are the whole quantity of *fpirit*, ftrong and fmall, mixed together; *proof-fpirit*, a mixture of about equal parts of totally inflammable *fpirit* and water; and *faints* are what runs after the proof is come off, which is always a mixture of more water than *fpirit*.

The low-wines are commonly rediftilled, to get rid of the fuperfluous aqueous part, and are thus reduced to *brandies*, or proof-*fpirits*. The faints may alfo be ferved in the fame manner; and by this means the produce of the diftillery, which in the ftate of faints, or low-wines, could not be judged of, as to its intrinfic value, is reduced to a certain ftandard, and marketable ftrength.

In the diftilling the fermented liquor, when once the ftream falls from the ftrength of proof-*fpirit*, there immediately begins to rife with it a coarfe and naufeous oil, which, though not fo communicative as the firft, never fails to impregnate the whole ftream with its flavour. Hence all common *fpirits*, or *brandies*, are what the chemifts call dilute quinteffences; that is, they are mixtures of the ardent *fpirit* and effential oil of the concrete, only here let down to proof with water, and impregnated with a fmall proportion of a volatile acid. As foon as the proof falls off, the liquor grows milky; that is, the oil, which before remained diffolved in the ftrong *fpirit* is let loofe by an over proportion of water, and may be commodioufly feparated by the chemical glafs made for that purpofe.

The common cuftom of the diftillers is to continue the diftillation, as long as the liquor that runs off will take flame at a candle applied to the vapour of a fmall quantity thrown on the hot head of the ftill; and indeed there is a certain point of time, after which the *fpirit* that comes will not pay for the fire and labour, as not more than from a twelfth to a twenty fourth part of the *fpirit* will come over in the water. With other views, however, fuch as the obtaining a more fixed vegetable acid, and a groffer effential oil, the operation may be continued till the danger of an empyreuma comes on.

The matter remaining in the ftill, after the operation is ended, has feveral ufes, and may in particular be made to afford Mr. Boyle's acid *fpirit* of wine.

When by repeated diftillation, without addition, any *fpirit* is entirely freed from its aqueous part, it is then called *alcohol*, *totally inflammable fpirit*, *rectified fpirit*, or, in the vulgar phrafe, *fpirit of wine*. On thefe general obfervations, it will be eafy to form fome new practical methods for the improvement of diftillation, as ufed in the way of making inflammable *fpirits*, or *brandies* for fale.

As the fermented liquor affords different parcels of matter of different degrees of fpecific gravity, and of volatility, when a pure feparation of the lighteft part is intended, the fire fhould never be raifed to a boiling heat, which jumbles and confounds all the parts together, rather than feparates them.

In the chemical way this rule may be practifed to great advantage, but great difficulties will attend the obfervance of it in the common bufinefs of diftillation. To render it more commodioufly practicable, thefe two methods may be propofed. 1. The encreafing the height of the ftill above the liquor. And 2. the working by a balneum mariæ, inftead of a naked fire.

As to the firft method it has been expected, that by raifing the ftill-head to the height of two or three yards above the liquor, a boiling heat would carry up the pure inflammable *fpirit*, without any confiderable mixture of phlegm, and yet continue to run in a full ftream from the nofe of the worm: but this does not anfwer to expectation in all particulars, but all the attempts that have been made towards it fhew, that the method is ftill improveable. The ferpentine-pipe, ufed in this fort of diftillation by Lemery, and fome others, though it occafions the *fpirit*, as it creeps up, to depofit a great part of its phlegm, yet has this great objection attending it, that the *fpirit* itfelf will not rife in it without a boiling heat, which never fhould be ufed in a fimple feparatory diftillation, becaufe it throws up fo much oil, as to foul at leaft the breaft and head of the ftill, and bottom of the pipe, whence it infects the fubfequent *fpirit* that wafhes them.

It is evident that this method may be brought to a greater perfection than it yet has been, but the other method, by the balneum mariæ, is preferable on fo many accounts, that it is better to bend our thoughts this way in attempting the improvements fo much wanted, and which would be fo beneficial.

By a proper regulation of the balneum mariæ, we may hope for a pure *fpirit* almoft at the firft extraction. Such an expectation will not appear unreafonable to any one, who will compare the *fpirit* drawn in the common method by the balneum mariæ, where the water is made to boil violently all the time, with another parcel of the *fpirit* prepared from the fame fermented liquor by the hot ftill. The difficulties of working from wafh, in this way of the balneum mariæ, are indeed very confiderable, efpecially in regard to the common malt-diftillers, with whom cheapnefs and difpatch are the only things in view; for to work at the fame time both quick and perfect, is an art not yet learned in the diftilling trade.

The whole application of the balneum mariæ, in this matter, depends on a fuitable engine and apparatus, and perhaps a large and long rectangular boiler might be commodioufly turned into the fort of balneum we are recommending; and this might be fitted with a great number of low alembics, which would work day and night with a very little fire, and ftill lefs attendance. The contrivance in general is obvious; but the great art would be the avoiding encumbrance and lofs. A large number of ftills are abfolutely neceffary, but no worms or refrigeratories are required to them, and by an eafy apparatus, the large number of thefe fmaller ftills may be charged with as much eafe as one great one. When the operation proceeds fo flow, as not to anfwer the cofts, the bottoms of all thefe ftills may be emptied into one large common ftill, and worked off in the ufual way for a coarfer commodity, that may afterwards be rectified.

In order to procure the *fpirit* from the fmaller ftills perfectly pure, the water of the balneum is to be not quite fcalding hot.

By this means, when tried in little, a furprifingly cool and almoft infipid *fpirit* has been obtained at the very firft extraction, though mixed with a confiderable proportion of phlegm, fo that it required no manner of rectification to fit it even for the nicer ufes. The method is curious and ufeful, though it were found worth while thus only in fmall; but will become greatly beneficial to the large dealer, if it could be reduced in the fame methods to practice.

In the common method of fimple diftillations, all means fhould be ufed to prevent the groffer effential oil from getting into the *fpirit*.

Thefe means have regard to the preparation of the fermented liquor, the regulation of the fire in diftilling, the ufe of percolation, and the keeping out the faints.

As to the manner of preparing the fermented liquor, and clearing it of its grofs oleaginous fæces, before it is committed to the ftill, the beft method is to let it ftand fome time after the fermentation is wholly over, that it may depofit all that it can, and become as thin and limpid as may be; and one great means of arriving at a perfection in this refpect, is the making the liquor fufficiently thin; if it be too thick and rich of the ingredient, the *fpirit* muft be coarfe. The liquor thus prepared, muft never fill above two thirds, at the utmoft, of the ftill. A boiling heat is neceffary in this operation; but then care muft be taken that this be not carried too far, and that the whole proceeds uniformly and regularly. The fire muft be kept as even as poffible, and never raifed by ftarts; for that never fails to throw over the coarfe oil, and foul the *fpirit*; fo that, if poffible, the operation fhould begin and end with the fame uniform and invariable degree of heat.

Another method of keeping the groffer oil, at leaft in fome degree, from mixing itfelf with the *fpirit*, is by ftretching a piece of very thick and woolly flannel over the mouth of the ftill, or by fuffering the fteams to pafs through the fame fort of flannel feveral times doubled, and placed at the nofe of the worm. It is furprifing what a large quantity of grofs fetid, offenfive, and unctuous matter will be thus collected, efpecially in the diftilling of malt *fpirits*.

The faints fhould never be fuffered to run among the finer *fpirits*, on account of the large quantity of this grofs oil, or greafy matter, they contain; efpecially if the fire be encreafed, as it ufually is, in order to bring them over. Some of the larger dealers, who value proof more than purity, will always have a dofe of this to give their goods a face, and keep up a head a proper time. This prevailing fondnefs for a ftrong proof, however abfurd in itfelf, is one great reafon why the generality of malt *fpirits* are no clearer. This caution of keeping out the faints fhould alfo extend to the keeping out a little of the firft running, which alfo, in this operation, is a kind of faints, as containing largely of the oil of the concrete, though much more fubtle than that in the proper faints. A farther regard muft alfo be had to the ftill-head and worm, through which the faints have once paffed, as thefe depofit in the head, and along the whole

length of the worm, a coarfe and naufeous oil, which will give a difagreeable flavour to a very large quantity of pure *fpirit*.

When the worm is once infected with this oil, it penetrates fo deep into the pores of the metal, that a fimple wafhing will not get it out, but rather it ought to be filled with a lixivium boiling hot, or elfe fome pure and highly-rectified *fpirit* fhould be put into it, and left in it a whole night, to imbibe and carry off with it the oil. Thefe are cautions that may feem trifling, but they are in reality of fo much confequence, that if rightly attended to, a much purer *fpirit* will be drawn off this way, than by any other common method. *Shaw's* Effay on Diftillery.

Proof Spirits, or *common faleable goods*, are *fpirits* of any kind of a determinate ftrength, being the fame with that of good brandy, and the malt and fugar *fpirits* of the diftillery, as they are ufually fold; containing equal quantities of rectified *fpirit* and water.

The common method of examining whether *fpirits* have this due degree of ftrength is this. Take a long vial, fill it half way with the common malt *fpirit*, and give it a fmart ftroak by its bottom againft the palm of the hand, there will then appear on the furface a chaplet, or crown of bubbles, which will go off again in a ftrong manner; that is, firft remaining a while, and then going off by degrees without breaking into fmaller bubbles, or fwelling into larger.

By this experiment all the traders in *fpirits* judge of the ftrength of the goods they purchafe, yet this is a mere fallacy and deception; for if only a little vinous, or faccharine matter, as treacle, fyrup, muft, rob of fruits, or the like, be added to a quantity of highly-rectified *fpirit* of wine, this flight addition will give a brandy proof to that *fpirit*.

Whether there be any fecret for making weaker *fpirits* fhew this proof, as well as brandies, *&c.* is not certainly known, but the thing is certainly practicable, fince arrack, which is but of half the ftrength of brandy, gives as fair a proof this way; and if a drop or two of any effential oil be added to a pint of brandy, it takes off its proof, and makes it appear much weaker than it is. The true ftrength may, however, always be known, by carefully burning away a meafured quantity of brandy, *&c.* fince if it leaves one half water, it is right, if more or lefs, it is too ftrong, or too weak.

But befide the falfe method of judging of brandies by what is called *proof*, there is another not lefs fallacious one of judging of their goodnefs, though kept as a great fecret in the hands of fome dealers, and imagined a certain criterion to determine whether foreign brandies are mixed with corn *fpirits*. Thefe diftillers are provided with a certain yellow liquor, a few drops of which being poured into a glafs of right French brandy gives it a beautiful blue colour, and by the ftrength, and goodnefs of this colour, they judge and buy; but if common malt *fpirit* were tinged with oak, it would give this colour equally with French brandy, and might be purchafed as fuch. This proof-tincture is expeditioufly made, by diffolving a little green vitriol, firft calcined to a rednefs in a weak *fpirit* of fea-falt, which thus becomes a yellow liquor, a fingle drop or two of which being added to a glafs of any inflammable *fpirit*, coloured yellow or brown with oak, or with long remaining in the cafk, will inftantly turn it of a bright and beautiful blue.

The beft way of judging in thefe cafes is by the nofe and palate. Dilute a quantity of brandy confiderably with water, and you will perceive the malt-tafte, if mixed with malt *fpirits*; or burn a little in a fpoon, and by the fmell and tafte of the water it leaves, you will eafily judge whether there be malt in it. *Shaw's* Lectures, p. 125, 126.

Proof fpirits may be diftinguifhed into three kinds, *perfect proof, more than perfect proof*, and *lefs than perfect proof*. By *perfect proof* is ufually underftood that crown of bubbles, before mentioned, of a certain fize, arifing as a head upon a fmall quantity of a well-qualified *fpirit* fhook in a flender vial.

Proof more than perfect, is that in which the bubbles, raifed by fhaking the *fpirit*, are larger than thofe on the common or perfect proof, and go off more fuddenly; that is, according as the *fpirit* is higher, or approaches more to the nature of rectified *fpirit*, or, as it is ufually called, *fpirit of wine*.

Proof lefs than perfect, is that wherein the bubbles are fmaller, and go off quicker and fainter than in perfect proof; the *fpirit*, in this cafe, being mixed with more than its own quantity of phlegm, or is too poor for fale.

In commerce, with regard to *fpirits*, it would certainly be a much better method to abolifh fuch uncertain proofs, and to make all the goods of the ftrength of what we call *fpirits of wine*; that is, a totally inflammable *fpirit*, whofe purity is much greater, whofe ftrength may always be found out with exactnefs, and whofe bulk, ftowage, carriage, and encumbrance, would be only half, in regard to that of *brandy* or *proof fpirit*; and it might at all times, as occafion called for it, be mixed into a great variety of extemporaneous liquors, and the exact degree of ftrength would be always precifely known. See the article *Rectified* Spirits, infra.

This operation, indeed, in the common way, proves fo tedious and expenfive, and, after all, fo fhort of expectation, and fo generally unfatisfactory, that it is not to be expected that the common diftillers, till they have fallen into a better manner of working, fhould come into the propofal. But if, inftead of the common way of rectifying by the hot-ftill, they would try the ufing a large balneum mariæ, made of a large rectangular boiler, and a fet of tall conical veffels, they will find that little fire, and little attendance, and confequently very little expence, will, in this manner, furnifh them with *fpirits* reduced at once to this ftandard, and greatly fuperior, in all refpects, to the common ones of the fame ftrength. In this cafe there would be no need of any addition of falts; but the diftiller may work more perfectly, and more expeditioufly without them, and thus preferve the fine effential vinofity of the *fpirit*, which in the common way of working they conftantly lofe.

The advantage of this method would be yet greater to the apothecaries, and the makers of compound cordial waters, who want only a pure *fpirit* of fuch a ftrength, and fuffer greatly in the finenefs and perfection of their commodities, by the *fpirit* they are obliged to ufe having in it a fulfome and naufeous oil of its own, which will always mix itfelf with their compofitions, and the oils of the aromatics, *&c.* which they add to it. If *fpirits* were brought to this ftandard for the market, there would be no poffibility of deceit, and no farther examination need be made of it by the buyer, than its burning perfectly dry in a fpoon. *Shaw's* Effay on Diftillery. See the article Strength.

It is however to be obferved, that though the burning *fpirits* away in a fpoon may ferve the trader in the common way, yet Mr. Geoffroy has obferved that they are no proofs for the philofopher, or the chemift, being not at all determinate or exact, though commonly fuppofed fo.

From what has been faid, it appears that brandy is much more inflammable than wine, and *fpirit* of wine much more fo than brandy, and ought to burn away without leaving any remainder. Hence it is vulgarly fuppofed, that fuch *fpirit* of wine as burns wholly away contains no phlegm, and that if two parcels of *fpirit* both burn wholly away in this manner, they muft be the fame in ftrength, and in all their qualities; but Mr. Geoffroy has proved by experiment, that fuch *fpirit* as burns wholly away, does yet contain a great deal of water, and that two parcels both may burn thus away, and yet be very different; and that this trial is not determined by the entire abfence of the phlegm, but by its proportion to the oil.

If the fame *fpirit* of wine, which in the common way of burning leaves no water, be again tried, by burning it in a hollow veffel fet to float in a large quantity of cold water, it will then leave a confiderable quantity of water; nay, all that is rectified only in the common way leaves a large portion of phlegm on this experiment. The plain reafon of which is, that this is the only fair trial, the other in the common way being fallacious. In this there is no more water left than was in the *fpirit*; but in the other, the veffel becoming heated by the burning of the *fpirit*, that heat gradually evaporates the water, as the *fpirit* burns away; fo that the one is as foon gone as the other. But keeping the veffel cool by external water, prevents that evaporation, and confequently retains and difcovers all that cannot burn of the *fpirit*.

The quantity of water thus difcovered in *fpirit* of wine is very great, and it has always been found, that in proportion as the experiment has been made more and more perfect, the *fpirit* has always appeared proportionably lefs and lefs fo.

The quality of the phlegm that is left, is alfo of ufe to judge of the *fpirit* by; if that were perfectly fine, this ought to be perfectly limpid and clear, and without tafte or fmell: as it wants either of thefe properties, it is a proof of the want of perfection of the *fpirit* it is obtained from; but the greateft of all its defects, is its having a coarfe oil fwimming upon it, and giving the colours of the rainbow in different lights. Mem. Acad. Par. 1718.

Rectified Spirit, or *alcohol*. A perfectly *rectified fpirit* of wine, or fuch as is entirely freed from water, is a thing of frequent and neceffary ufe in the nice operations of chemiftry.

It had ufed to be prepared, either by often diftilling the *fpirit*, and every time drawing over only half of it, and repeating this till the half remaining in the cucurbit appeared as ftrong as that drawn over; or elfe by raifing it to a great height from the body of the veffel, and this in a very gentle heat, fo that *fpirit* alone could rife, the water not being capable of being driven fo far by that degree of heat.

But the accurate Boerhaave always found upon trial, that there was ftill remaining fome water in thefe *fpirits*, whether prepared by the firft or fecond procefs, or both. *Boerhaave's* Chem. Part 2. p. 124.

The method he therefore invented is this: fill a still half full with the *spirit* prepared for *alcohol* in one or the other of these ways, add to it half a pound of pure decrepitated, and perfectly dried sea-salt; put this in hot, then place on the head, and carefully lute the junctures; leave this for twelve hours in a heat so small, as not to make the *alcohol* boil, then distil off the *spirit*; keep the first two ounces apart, because some aqueous vapour may have happened to lodge in the head, or worm of the still, which this certainly washes off; after this receive two thirds of the following *alcohol* into a pure dry glass-vessel, and keep it perfectly stopped; then draw off the remainder, and keep that by itself: there will remain a moist salt in the still, which has attracted the aqueous matter of the *alcohol*, and held it so down, that it could not rise by the heat of boiling water, which is all that must be used in this distillation; and the salt having been first decrepitated, never makes any change in the *alcohol*, by adding any thing thereto. By this means an *alcohol* is prepared perfectly pure, and fit for all the uses of chemistry.

The *alcohol* thus perfected is the lightest of all fluids next to air; it is extremely pellucid, thin, and simple, and is totally inflammable, burning without smoak, and without leaving any fæces behind. It has no disagreeable smell in the burning, remains the same after distillation, is very expansive with heat, easily boils over the fire, is of a grateful odour, and agreeable taste. This fluid instantly coagulates all the juices of the body, except pure water and urine; it hardens the solid parts of the body, and preserves both the solids and fluids from putrefaction, or spontaneous resolution; it preserves the bodies of birds, fishes, insects, and other animals suspended in it, perfect for ages. It mixes almost uniformly with water, vinegar, any acid liquors, oils, and pure volatile alkaline salts; and dissolves gummy and resinous bodies. Hence we are acquainted with no liquor, either natural, or produced by chemistry, which will mix with more bodies.

It is in particular an excellent vehicle for the presiding *spirit* of vegetables, as by means of it that *spirit* may be commodiously extracted from its own body, and fitted for medicinal purposes. In the living human body it wonderfully raises, gratefully affects, and stirs the animal, natural, and vital *spirits*, whence it gives encrease to the strength, senses, and agility; but by its power of coagulating the blood, serum, and other juices, it may kill by being imprudently taken. It instantly stops bleeding, by at once contracting the vessels, and coagulating that blood which it touches at the mouths of them; and hence it is a sudden and powerful remedy in these cases.

If the parts of animals, or vegetables, suspended in *alcohol*, contain any thing oily in them, the *alcohol* immediately extracts it from the matter, which thence becomes shrunk, wrinkled, and withered; but small birds with their feathers on, and fish that are well covered with scales, remain perfectly preserved in their recent form, by being plunged in hot *alcohol*. When they have been long enough in the *spirit* to be perfectly penetrated by it, they may be taken out and dried in a slack oven, and afterwards put up in empty glasses well stopped, where they will remain beautiful specimens for ages. *Boerh.* Chem. Part 2. p. 126.

Alcohol being required on many occasions to be perfectly pure, and free from the least drop of water, it may be proper to add here the true and infallible rules of judging when it is so. These are the following.

1. If any oil be contained in the *alcohol*, it turns milky on being mixed with water.

2. If it contains any acid; when a little of it is mixed with *spirit* of sal armoniac, there will be an effervescence, otherwise there will be only a simple coagulation; and if any thing alkaline be contained in it, this will be discovered by the mixing it with acids; as for the other salts, they are scarce ever contained in the *alcohol*.

These are the tests of such admixtures, but they are the least common; water is the most frequent, and most to be suspected in it, and this is the most difficult to be discovered. To this purpose a little of it is to be fired in a spoon in a still place, where there is no wind moving, and if no water be left in the spoon, this is a fair step toward its answering expectation: this, however, alone is by no means to be depended upon. Gunpowder also put into a spoon, and covered with *alcohol*, if when the whole is burnt away it takes fire, gives another proof that there is but little water contained in it; but this does not prove, any more than the former, that there is none. After these trials, the surest is this: take a round chemical vial, capable of holding four or six ounces, and having a long neck; fill two thirds of this with *alcohol*, and add to it a drachm of pure salt of tartar well dried, and heated very hot; shake them well together, and hold them over the fire to make them just so hot, as that the *alcohol* does not quite boil. If after this the salt of tartar is perfectly dry, we may be assured that the *alcohol* contains no water, or if any, not to be discovered by any experiment hitherto known, unless by the water collected from its flame when perfectly burnt.

If after the salt of tartar has remained dry ever so long at the bottom of this pure *alcohol*, only a drop or two of water be added to it, the salt immediately becomes moist, and hangs about the bottom and sides of the vessel. To this it is to be added, that this pure *alcohol*, when distilled, gives no appearance of itself, either in the head or neck of the alembic, nor on the sides of the receiver; neither appearing like the aqueous fluids in moist drops, nor like good *spirit* of wine, running in veins, but remaining invisible to the eye, except at the bottom of the receiver. This property of *alcohol* was known to the antient chemists, as appears by their writings. *Boerhaave*'s Chemistry, Part 2. p. 127.

Water is a solvent to *alcohol*, or *spirit* of wine, in certain circumstances, but not spontaneously, or in all mixtures. If water be gently poured into it, it does not dissolve it, or mix itself with it, but falls through it, and collects itself into a separate body at the bottom of the vessel; as soon, however, as they are shook together, the *alcohol* begins to blend with the water, though at first, or with a little shaking, it only is dispersed in form of unctuous veins through the body of the water, but by continued shaking, they perfectly unite. As *alcohol*, therefore, is a pure vegetable oil, produced by a perfect fermentation, its nature is thus perfected, so as not only to burn in the fire, but to mix perfectly and easily with water: but water impregnated with salts will not dissolve *alcohol*, for a strong solution of salt of tartar in water, will not be brought to mix with *alcohol* by any shaking, nor even by boiling together; but as soon as the mixture has stood a little, the *spirit* gets to the top, and remains perfectly unmixed with the water. Salt of tartar unites itself more intimately than many other salts to water; and if another salt, which more easily separates from water, such as Epsom salt, be, in the place of salt of tartar, dissolved in water, though the solution be ever so strong, the liquor will dissolve *alcohol*; and on their being mixed together, the whole will become turbid and white, and the salt will be precipitated in crystals. *Boerhaave*'s Chem. Part 1. p. 452.

Water has also this remarkable quality, that if mixed with *alcohol*, in which any essential oil has been dissolved, it separates the oil from the *alcohol*. Thus if oil of cinnamon be dissolved in pure *alcohol*, and water be let fall into this solution, the mixture presently becomes white and opake, though it was perfectly pellucid before; and the oil separates itself from the *alcohol*, and gathers into a body. Hence it appears, that *alcohol* is disqualified by water for the dissolving of these oils; that it also more easily and readily unites with water than with them; and finally, that these essential oils, while they appear to be wholly dissolved in the *alcohol*, and no longer look like oils, but like *spirit*, yet are really oils, and easily separable in their true form. *Boerh.* Chem. Part 1. p. 453.

Proof *spirit* cannot be used for burning in lamps, for dissolving rosins, for making varnish, and there are a great number of tinctures, solutions, and mixtures, for which it cannot serve; but *alcohol*, beside its ready use in the medicinal way, may, when the *spirit* is of a proper kind, be made into punch, and all other mixtures, with more purity, and a great deal more certainty and exactness in point of strength. *Shaw*'s Essay on Distillery.

Colouring of SPIRITS. The art of giving to distilled liquors a colour, which takes off their watery appearance, and gives them a resemblance of the foreign brandies, &c.

The colouring is not only necessary on this account, but as we usually esteem the *spirits* by the proof of the crown of bubbles, it is found that the clean rectified *spirit* will not afford this proof till it has received its dose of the colour. The distillers dispense this colour in any proportion that they find convenient or necessary: it is always yellow, but according to the degree differs extremely in deepness, from the palest straw colour to the deepest orange. This art of colouring was first introduced, from observing that all the fine and soft foreign brandies, that had the mellowness necessary to their perfection to the taste, had also a yellow colour. The colour, in this case, has indeed nothing to do with the flavour; but that being kept in casks the same age that was necessary to give them this mellowness, would also give them a colour from the wood. It was hence supposed, that the particular excellence of the foreign brandies depended on the woody colour, and accordingly have been taken to give the same colour to our *spirits*, by various methods.

The way of obtaining it, by many years standing in the cask, proved too tedious for our hasty workmen, and accordingly they provided means of giving it extempore by strong tinctures of several ingredients; the chief of which are logwood, saffron, Japan earth, treacle, burnt sugar, and oak chips: the three former of these have but little to recommend them, but the others are found very ready, and very proper for the use.

Treacle gives a fine colour, not much unlike that of the foreign brandies, and being necessarily used in a large quantity, as its colour is but dilute, it not only mends the bubble, or

or bead proof, impaired by the rectification, but also gives it a fullness in the mouth; both which properties are very agreeable to the vulgar, who are the chief retail consumers of these coarse goods.

Burnt sugar, that is, sugar dissolved in a little water, and scorched over the fire till it turns black, goes much farther in the colouring than treacle, and at the same time gives no sweetness, but rather an agreeable bitterness; and thus recommends itself to the nicer palates, that are not for a luscious *spirit*. Indeed sugar, thus treated, tinges to a great perfection, and that without loss of time, and with as much cheapness as can well be desired.

The last article mentioned, namely, oak chips, is of all others the most natural for the imitating the dye of foreign *spirits*, as it is the very wood whereof the casks they come over in are made, and from which they take that colour we are so fond of. The colouring with oak has also this farther advantage, in *spirits* meant as sophistications of the foreign ones, that it will stand some tests usually had recourse to on the occasion, which the others will not stand.

Common *spirit* poured on oak chips, and digested in a moderate heat, easily fetches out this resinous part of the wood, on which the colouring depends; but then it does not go near so far as the burnt sugar; a large quantity of oak being required to colour a small parcel of brandy, or *spirits*. It is adviseable not to make the tincture every time, but to have recourse to an extract of this wood in a liquid form: this extract is best made in two menstruums, alcohol and water, and may be evaporated to any strength, so that a very small dose of it will tinge a great quantity of liquor. The two liquid extracts must be mixed together, and as they will be apt to separate in standing, it will be proper to add to them, when newly made, a quantity of fine sugar; this will give a body to the whole, and it will keep better from mouldiness than it would without it. *Shaw*'s Essay on Distillery.

Convertibility of SPIRITS. This is a doctrine that has obtained among many of the most curious experimenters, and indeed the most intelligent of our chemists have always allowed, that provided proper care were taken in the getting together the materials, one *spirit* may always be changed into another, as brandy into rum, malt *spirit* into brandy, and brandy into malt *spirit*. The principles on which this is believed are these.

All simple *spirits* (as they are called) consist of four parts, water, oil, phlegm, and alcohol: the last of these is the essential part, and is what constitutes the whole a *spirit*. In reducing *spirits*, therefore, to their utmost degree of simplicity and purity, it is evident that the three superfluous parts are to be got rid of, and the fourth left alone; by this means the alcohol is procured distinct, and is a liquor *sui generis* of many peculiar qualities, not to be found in any other fluid.

Among others it has these remarkable properties. 1. When absolutely purified, it is an uniform and homogene liquor, capable of no farther separation, without loss or destruction of some of its homogeneous parts. 2. It is totally inflammable, having no soot, nor any moisture behind. 3. It has no peculiar taste or flavour, any more than pure water, except what is owing to its nature as alcohol, or perfectly pure *spirit*. 4. It is an unctuous and crispy fluid, running veiny in the distillation, and its drops rolling on the surface of any other fluid, like pease upon a table, before they unite. 5. It appears to be the essential oil of the body it is obtained from, broken very fine, and intimately and strongly mixed with an aqueous fluid, which is assimilated, or changed in its nature in the operation. 6. And lastly, it seems to be a kind of universal fluid, producible with the same properties from every vegetable subject; but to produce it thus, requires some care in the operation.

On these principles is founded the opinion, that all *spirits* may be reduced to a perfect similarity, or sameness, from whatever subject they were procured, and on this depends their convertibility into one another; for when once they are brought to this standard of simplicity, there needs nothing more than to add the oil of such of the finer *spirits* as is required to convert the *spirit* into that particular kind. By this means the same tasteless *spirit*, whether obtained from malt, sugar, or grapes, may be made into either malt *spirit*, brandy, or rum, by adding the essential oil of the grape, sugar, or malt; and thus what was once malt *spirit*, shall become brandy, or whatever else the operator pleases.

Many methods have been attempted to obtain the first point, that is, the reducing the *spirit* to perfect and pure alcohol. The most practicable means seem to be long digestion, and the repeated distillation from water into water, where the essential oil will at once be left upon two surfaces, and the acid imbibed. The shorter ways are those by rectifying from neutral absorbent salts and earths; such are sugar, chalk, and the like. And lastly, the use of fixed alkalies may be tried, for these very forcibly keep down both the phlegm and oil; insomuch that this last method promises to be the shortest of all, if the art were known of utterly abolishing the alkaline flavour, which the alcohol is apt to acquire in this operation, and which, for this purpose, is by no means suitable, as absolutely destroying all vinosity, which universally consists in a fine volatile, pungent acidity. The distillers are the only people, whose business would lead them to make the experiment. This method of converting one *spirit* into another, would be of immense profit to them if they could perfectly succeed in it; but as it would require time and slow processes to bring it about, there is but little hope of its ever being brought to bear among them, while they are in their present scheme of doing every thing with dispatch and hurry.

Dr. Shaw has said a vast deal in the praise of a tasteless *spirit*, which is producible from a vegetable substance, only overlooked, as he tells us, because it is too common, with which all the foreign *spirits* might be imitated to the utmost perfection by means of their essential oils, all thin fine wines raised to any due degree of strength, without giving them the brandy flavour, and many other things of great use performed; but he has not told us what the vegetable substance is from which we are to obtain this. *Shaw*'s Essay on Distillery.

SPIRITS, in medicine, are of use, in external applications, to wounds and sores. They stimulate sores, resist putrefaction, harden the fibres, coagulate the liquors, hinder suppuration, and quicken the pulse when absorbed.

Tinctures of absorbent and aromatic powders are often made with the same intention, and partake of the nature of their ingredients, but principally of the *spirit*. Med. Ess. Edinb. Vol. 5. Art. 24. See the articles ABSORBENTS and AROMATICS.

The power of brandy, or any thing of this kind, in killing worms, is evident from this, that the children of the people in the northern islands of Scotland, who are accustomed from their infancy to drink that coarse sort of brandy which they call *aqua vitæ*, never are troubled with worms. It is a dangerous practice to use brandy in this general manner, but on some occasions it may be very serviceable. Philos. Trans. N° 233.

The danger of the frequent and immoderate use of *spirits* is too well known from experience, and acknowledged by physicians; but a late ingenious writer thinks it not improbable that many, especially ladies, are led gradually to the use of those poisons by a certain complaisant pharmacy, too much used in the modern practice: thus palsy-drops, poppy-cordial, plague-water, and such like, which being in truth nothing but drams disguised, yet coming from the apothecaries, are considered only as medicines. He therefore recommends to them the use of tar-water, a cordial not only safe and innocent, but giving health and *spirit* as surely as other cordials destroy them. See TAR-*water*.

The *spirits* of wine, or other fermented liquors, produce irregular motions, and subsequent depressions in the animal *spirits*; whereas the *spirit*, lodged and detained in the native balsam of pines and firs, is of a nature so mild and benign, and proportioned to the human constitution, as to warm without heating, to cheer, but not inebriate, and to produce a calm and steady joy, without that sinking of *spirits* which is a subsequent effect of all fermented cordials.

Acid SPIRITS. *Acid spirits* extracted from fossils, and applied to animal bodies, coagulate the liquids, and mortify the solids; by being diluted with water, they approach to vinegar.

By dissolving metallic substances in these *spirits*, their corroding sphacelating power is increased, and some of them give such pain, as to bring on convulsions. Med. Ess. Edinb. Vol. 5. Art. 2.

Ætherial SPIRIT *of Frobenius*, *spiritus ætherius Frobenii*, a name given by Frobenius, and others, to a liquor famous for its extreme volatility, and many other qualities, and prepared by him in this manner. Take four pounds of the best oil of vitriol, and the same weight of rectified *spirit* of wine: first pour the *spirit* of wine into a glass retort, and then pour to it, by little and little, an ounce of the oil of vitriol, shake the retort till the two liquors are thoroughly mixed; the vessel will then begin to grow warm; then pour in more of the oil of vitriol, shaking it again, and so on, putting in an ounce of the oil of vitriol at a time, and allowing about an hour's time for making the whole mixture, least the sudden violent heat they excite should burst the vessel. When the whole quantity is perfectly mixed, place the retort in a sand-furnace, the heat of which is as near as possible the same with that of the vessel, which will be at this time very considerable; take out some of the hot sand, and place the retort in the center of the rest; then adding more of the hot sand round it, apply a large receiver to the nose of the retort; let this receiver be placed on a vessel of cold water, and covered with a double flannel wetted with cold water; raise the fire gradually, till the drops fall so fast, that you may count five or six between each; and beside these drops, the upper hemisphere of the receiver appears filled with a white vapour. This heat is to be continued so long as the *spirit* smells like sweet marjoram; as soon as this aromatic flavour goes off, and the smell

ſmell becomes acid and ſuffocating, like that of brimſtone; take away the receiver, and put out the fire, for all that ariſes after this period is only a gas of ſulphur, and is of no uſe.

The greateſt precaution muſt be uſed in this whole diſtillation, otherwiſe the liquors in the retort will run over into the receiver; the fire muſt ceaſe, as ſoon as the *ætherial ſpirits* are gone over, for there remains behind an oleum vini, which is extracted out of the *ſpirit* by the force of the acid, and will ariſe in the retort, and often runs over, or cauſes exploſions. On the ſecond day, when the retort is cold, pour on the matter that remains in it half as much alcohol, or rectified *ſpirit*, as at firſt, that is two pounds by weight; and then repeating the whole proceſs of the diſtillation, exactly as before, there will come over half as much as at firſt of the *ætherial ſpirit*. On the third day after this proceed in the ſame manner, and you will have ſo much more. In this manner the operations are to be repeated, till no more *ætherial ſpirit* can be raiſed, and all turns to a carbo. Then ſeparate it, and alkaliſe it with *ſpirit* of ſal armoniac, made without *ſpirit* of wine, till all effervеſcence ceaſes; then diſtil it once more in a balneum mariæ, and it is fit for experiments.

There are more products to be got out of the proceſs. 1. A balſamic oil. 2. A terra-foliata tartari, which is of a glittering hue, and is not fuſible as the common one, prepared with vinegar and the fixed ſalt, is. This is very uſeful in medicine. And 3. a purple earth is to be extracted out of the caput mortuum. Phil. Tranſ. N° 461. p. 870.

The properties of the *ætherial ſpirit* are, 1. That it is ſo extremely volatile, that it evaporates immediately, and does not appear to wet the finger which is dipped in it. 2. That it is ſo extremely inflammable, that it will take fire at a very great diſtance from any flame. 3. That it is of a very pleaſant and aromatic ſmell. And 4. that it does not mix with water.

We have ſeveral curious obſervations on this *æther of Frobenius* by Mr. Groſſe, in the Memoirs of the Academy of Sciences. This Gentleman had obſerved, that in diſtilling *ſpirit* of wine from a ſolution of alum, there was produced a liquor of an agreeable aromatic ſmell, not unlike that of the *æther*; and on this principle he conceived an opinion, that this *æther* was not to be ſought in the common oils of plants, but in ſome mixture of *ſpirit* of wine with a vitriolic acid: and Mr. Geoffroy's papers affording ſome hints alſo to the ſame purpoſe, Mr. Du Hamel, in concert with Mr. Groſſe, determined to attempt the diſcovery with the utmoſt pains on this baſis, and after many unſucceſsful trials, Mr. Groſſe found out three different methods of making it, of which he gives the following account.

Take a pound of pure, uncoloured, and well-rectified oil of vitriol, and two pounds of well-rectified *ſpirit* of wine. The oil of vitriol muſt be firſt put into a retort, and the *ſpirit* of wine afterwards added by a little at a time. There ariſes a very violent heat on the mixing theſe liquors, and the mouth of the retort is to be ſtopt when they are mixed, and the veſſel ſet by for two or three days; in which time the mixture aſſumes a reddiſh colour. After this the retort is to be placed in a ſand-heat, and the diſtillation being made, there firſt ariſes a ſmall quantity of very ſweet ſcented *ſpirit* of wine; after this there ariſes another liquor in white clouds; and after this, on continuing the diſtillation, there comes over another, which is very ſulphureous and volatile, and very ſtrongly affects the noſe, and would indeed ſuffocate a perſon, if its vapours were received in large quantities. After this there ariſes an acid phlegm, and what remains in the retort is a black maſs.

It appeared very plainly by the ſmell, that the *æther* was contained in theſe diſtilled liquors, the manner of ſeparating it was the only difficulty; and after ſeveral tedious experiments with ſal armoniac, and other things, Mr. Groſſe happily thought of trying common water, as the moſt ſimple and eaſy of all methods, to weaken both the ſulphureous acid and the *ſpirit* of wine, which he judged the only obſtacles to the *æther* from ſhewing itſelf in its true form; and this was founded on that remarkable property of the *æther*, of not mixing with water, though blending itſelf very readily with *ſpirit* of wine. On pouring a large quantity of water on theſe diſtilled liquors, the *æther* immediately ſeparated itſelf from the reſt, and by reaſon of its extreme lightneſs roſe all at once to the ſurface of the water. This did not, however, yield it perfectly pure; but adding a little ſalt of tartar to this, the remainder of the acid ſulphureous *ſpirit* was abſorbed, and the *æther* obtained perfectly pure and fine, as that made by Frobenius himſelf.

As the *æther* had been by this means ſeparated from the whole diſtilled matter, it did not clearly appear which of the ſeveral different matters, that ſucceeded one another in the diſtillation, contained it, the reſt ſeeming only a load to the proceſs: with this thought Mr. Groſſe, to try by the ſmell which was moſt likely to contain it, in a ſucceeding diſtillation pricked the bladder, that luted the junctures of the retort and receiver, with a pin, and judging of the ſeveral liquors, as they ſucceeded one another, by their ſmell, he determined that the firſt was only a very highly-rectified *ſpirit* of wine; the ſecond, which came over in white clouds, ſmelt very ſtrongly, and perfectly like the *æther*: this ſeemed indeed the whole matter of the *æther*, the reſt ſerving only to abſorb it. The third liquor had a very penetrating and ſuffocating ſmell of ſulphur.

From theſe obſervations this gentleman attempted the making the *æther* in this ſecond manner. All being prepared as before, he diſtilled off the *ſpirit* of wine, or firſt liquor, and as ſoon as the white vapours began to appear in the retort, he took off the fire, for there was no doubt but the remaining heat was ſufficient for the diſtillation of ſo very volatile a liquor as the *æther*. This ſucceeded accordingly, and the clouds all coming over, and the remaining *ſpirit*, or third liquor, remaining behind in the retort, the *æther* was now found in the receiver, mixed only with a ſmall quantity of *ſpirit* of wine, or with a very ſmall portion, at the utmoſt, of the ſucceeding *ſpirit*. An addition of water ſeparates the *æther* from the *ſpirit*, as in the former proceſs, and if it be not ſufficiently dry and clean when thus procured, it may be diſtilled over again with a gentle heat; and it is remarkable, that if it be diſtilled this ſecond time, without previouſly adding any water, it comes over firſt into the receiver; though the *ſpirit* of wine comes firſt in the common, or primary operation.

Theſe are very ſimple and eaſy ways of making this famous *ſpirit*; but though they uſually ſucceed, yet they have ſometimes failed, even in the hands of the inventor, and that though all the circumſtances of the proceſs have been the ſame, the failure being owing to ſome imperceptible difference, either in the oil of vitriol, or in the *ſpirit* of wine; though this, however, has ſometimes made the proceſs fail in the two former ways, Mr. Groſſe adds a third, in which he obſerves that it always ſucceeded with him.

By this method the *æther* is procured perfectly dry and pure, without the mixture of water, or of the alkaline ſalts. For the ſeparation, or purification of it, the method is this: when the white vapours have appeared, the whole matter in the receiver is to be poured into a ſmall retort, which being placed over a lamp, the *æther* will immediately riſe, and diſtil into the recipient; when half the liquor is come over, or, at the utmoſt, two thirds of it, the lamp is to be taken away, that the *ſpirit* may not riſe, and make a new mixture. Thus the pure *æther* is, without farther trouble, found in the receiver. Mem. Acad. Par. 1734.

Coal-Spirit. See the article Coal-*ſpirit*.

Fœtid Spirit, *ſpiritus fœtidus*, a new medicine introduced into the practice of phyſic, and directed to be made of any fixed alkaline ſalt a pound and half, ſal armoniac a pound, aſſa fœtida four ounces, and proof-*ſpirit* three quarts, diſtilling off five pints with a gentle heat. *Pemberton's* Lond. Diſp. p. 205.

Foreign Spirits, a general name by which our dealers in theſe things call brandy, rum, and arrack.

It is hard to purchaſe any of theſe genuine and pure, unleſs at the firſt hand, and in large quantities. The dealers generally mix our own *ſpirits* with them. When we had little other *ſpirit* but that of malt made with us, this cheat was eaſily diſcovered, for a nice palate would diſtinguiſh the mixture of only a tenth part of this foul *ſpirit* among the foreign clean ones; but ſince we have the melaſſes *ſpirit* ſo common, and rectified to ſo great a perfection, the deceit is not eaſily found out, though a larger proportion is uſed.

All *foreign ſpirits* are to be ſuſpected of this adulteration, which have not an uniform taſte, and grateful odour. But one of the beſt ways of diſcovering the mixture, is to burn away all that is inflammable in a ſmall quantity by way of trial, and then examine the phlegm.

The great art of this ſophiſtication conſiſts in the purity, and well rectified ſtate of the *ſpirit*; and when the diſtiller can furniſh himſelf with ſuch a *ſpirit* as will not be found out, though mixed in a large quantity with brandy or rum, he is very near the art of making brandy and rum himſelf. *Shaw's* Eſſay on Diſtillery.

Spirit *of lavender*, a form of medicine, which has been uſed to be compounded of a vaſt number of ingredients; but the late London Diſpenſatory has greatly ſhortened the catalogue of them, by ordering this to be made only of lavender flowers and roſemary tops, or the ſimple *ſpirit* of each; and the addition of cinnamon and nutmeg, of each half an ounce, and red ſanders three drachms to two quarts of the *ſpirit*. The ſimple *ſpirits* are to be mixed in the proportion of three parts lavender, and one part roſemary, or elſe the ingredients proportioned in the ſame manner. *Pemberton's* Lond. Diſp. p. 248.

Malt-Spirit. See the article Malt-*ſpirit*.

Spirit *of melaſſes*. See Melasses-*ſpirit*.

Glauber's Spirit *of nitre*, *ſpiritus nitri Glauberi*, in pharmacy, a form of medicine made thus: take of nitre three pounds, and of the ſtrong *ſpirit* of vitriol one pound; let them be mixed with caution, and gradually, under a chimney; and afterwards let them be diſtilled, firſt with a gentle heat, and then with a ſtronger. *Pemberton's* Lond. Diſpenſ. p. 191.

Dulcified Spirit *of nitre*, *ſpiritus nitri dulcis*, a form of medicine ordered to be made thus: take of rectified *ſpirit* of wine one quart, and of Glauber's *ſpirit of nitre* half a pound; mix them by pouring the *ſpirit of nitre* on the other, and diſtil the mixture with a gentle heat, as long as what comes off will not raiſe any fermentation with a lixivial ſalt. *Pembert.* ibid. p. 198.

This is much uſed by our diſtillers to give a vinoſity to thoſe *ſpirits*, whoſe natural flavour of that kind they have deſtroyed by the improper uſe of alkaline ſalts in the rectifications. Nothing can be more proper for this purpoſe than this *ſpirit*, as it really gives the brandy flavour, and is not at all prejudicial to health, but very well falls in with the nature of the *ſpirit*, and promotes its medicinal properties as a diuretic, deobſtruent, and lithontriptic.

In order to bring the uſe of this *ſpirit* to a greater certainty and perfection, it is to be obſerved, 1. that there is a great difference in *ſpiritus nitri dulcis*, according to the manner of its preparation; ſuch of it being moſt apt to fly off from the *ſpirit* as had leaſt pains taken about its incorporation by digeſtion, or repeated diſtillation.

2. Any rectified clean *ſpirit*, impregnated with a proper doſe of *ſpiritus nitri dulcis*, and kept in a ſound glaſs veſſel cloſe ſtopt, will a long time retain that vinoſity it obtains from it, and which it would otherwiſe have loſt in a very ſhort time.

3. The caſks long uſed to receive rectified *ſpirits*, impregnated with this acid, uſually appear yellow and rotten, or corroded within like the bottom of a cork, which ſtops a vial of *ſpirit of nitre*. It hence appears no wonder that the vinous taſte, given by this addition, is ſooner loſt in the caſk than in a bottle.

4. When the inflammable *ſpirit* has been rectified with fixed alkalies, it always requires a much larger proportion of the *ſpiritus nitri dulcis*, to give it this vinoſity, than when rectified only by repeated diſtillation; and this vinoſity given by the acid is ſooner loſt, as the *ſpirit* was more impregnated by the alkalies uſed in the rectification. This is the reaſon of that odd obſervation, that melaſſes *ſpirit* retains the vinoſity given it by *ſpiritus nitri dulcis* much longer than malt *ſpirit*; the former having had little, if any, of the alkaline ſalt uſed in the rectifying it, of which the latter, by reaſon of its natural foulneſs, has had a great deal.

5. The beſt way of making this volatile acid, whether with or without external heat, is not uſually practiſed, *viz.* ſo as to render it a perfectly homogeneous and uninflammable liquor, whence it proves much more volatile than it ought to be. Thus when perfect alcohol, and a well rectified ſtrong *ſpirit of nitre*, are by degrees put together for the making of this vinous acid; one half of the mixture evaporates in the conflict, or may be made to diſtil away ſo, as to leave the other half more fixed. The method of making it is alſo improveable, by uſing in the preparation a *ſpirit* of wine impregnated with ſome fine flavoured ingredient, which has not much oil, for acids do not readily mix where there is much oil.

In the preparation of this *dulcified ſpirit of nitre*, the longer it ſtands in digeſtion with the *ſpirit* of wine, the milder it grows; and by the ſame means, alſo, the violently corroſive oil of vitriol may be ſo blunted, as to be rendered ſcarce perceptible to the taſte. In fine, a *ſpiritus nitri dulcis* may be made by a ſlow digeſtion, greatly ſuperior to that commonly uſed, and of ſo fixed a nature, that it will not be ſubject to have its flavour fly off from the *ſpirit* it is mixed with, any ſooner than the native vinoſity of brandy will of itſelf fly off from that *ſpirit*, as it always will in time. A proper care in the preparation of this acid might free the diſtillers from that troubleſome neceſſity they are under of adding their *ſpirit of nitre*, juſt before they ſend their goods away, for fear the flavour ſhould be loſt before the *ſpirit* is all uſed, and ſo the ſophiſtication be found out. There is no fixing any certain proportion, in which the acid is to be mixed with the *ſpirit*, but in general it is beſt not to overdo it; for though it will give an agreeable vinoſity to any tolerably clean *ſpirit*, the perſon will be much deceived, who attempts to drown the bad flavour of a foul one by it. *Shaw*'s Eſſ. on Diſtillery.

Spirit *of ſalt*. See the article Salt.

Strength of Spirits. See the article Strength.

Spirit *of ſulphur*, the ſame as oil of ſulphur. See the article Sulphur.

SPIRITO, in the Italian muſic, is uſed to ſignify that a performer ſhould ſing or play with vigour, life, and *ſpirit*. Hence we meet with *con ſpirito* in cantatas and ſonatas.

SPIRITUS *rector of vegetables*. See the article Archæus.

Spiritus *tartari*, the name of a medicine very famous in Germany, and probably in the greater eſteem, becauſe of the difficulty of preparing it. It is the *ſpirit* of ſalt of tartar volatilized; and is ordered by Langelot to be made in this manner: let two or three pounds of crude tartar be burnt to a blackneſs, in order to have what is moſt neceſſary, a ferment to ferment the tartar with; put this into a large pot, and pour to it ſo much water as will ſerve to ſtand an inch above it; make this mixture luke-warm, and then pour into it half a handful of crude tartar powdered; bubbles of air will ariſe upon this, and will continue ſome time; when they ſeem to decreaſe, more powdered tartar is to be added from time to time, to keep up this fermentation. The bubbles will be large, and riſe in cluſters, and reſemble bunches of grapes in all but colour. The fire all this time muſt be carefully managed, and the tartar put in gradually, that the fermentation do not become too great, or the pot run over.

After this the matter is to be put together into an iron retort, and a very gentle fire kept under it for ſome time, and gradually heightened, ſo as to force up all the ſalt; this being done, the volatilized ſalt is to be carefully ſeparated, and it is remarkable, that the ſalt is ſo wholly volatilized by this fermentation, that there ſcarce remains any fixed ſalts in the caput mortuum in the retort.

The liquor in the receiver is to be rectified by another diſtillation, the water, neceſſarily uſed in the fermentation, rendering it too weak. When it is rectified ſo far, that it appears whitiſh, it is known to be of a due ſtrength, and it is then the famous *ſpirit of tartar*, not only celebrated for its medicinal virtues, but famous for extracting tinctures that can be obtained from no other menſtruum. *Langelot*, de Digeſt. et Ferm.

Spiritus *volatilis aromaticus*, a name given of late to what uſed to be called *ſal volatile oleoſum*. The modern way of making it is this: take eſſence of lemons, and oil of nutmegs, of each two drachms, oil of cloves half a drachm, dulcified *ſpirit* of ſal armoniac a quart; diſtil the whole with a very gentle heat. *Pemberton*'s London Diſpenſatory, p. 205.

SPISSUM, in the antient muſic, was uſed to ſignify thoſe two ſmaller conjunct intervals of a tetrachord, which taken together, were leſs than the third. *Wallis*'s Append. Ptolem. Harm. p. 165.

The Greek term for this was πυκνον. This happened in the enharmonic, and the three chromatic genera; in each of which the interval, between the hypate and the lichanos, was leſs than the interval between the lichanos and the nete. To the *ſpiſſum* was oppoſed the *non-ſpiſſum*, ἀπυκνον, or *rarum*, as Martianus Capella tranſlates it. The ἀπυκνον happened in the two diatonic genera, where the two ſmalleſt intervals were equal to, or greater than the third. They were ſuppoſed equal in the diatonicum molle, and greater in the intenſum. *Wallis*, ibid. See the article Genus.

SPIZA, in zoology, a name by which the antient naturaliſts called the chaffinch. See the article Fringilla.

SPLANCHNICA, a name given to medicines appropriated to diſeaſes of the bowels.

SPLEEN (*Cycl.*)—Mr. du Vernoi has added one opinion more to the many already given, concerning the uſe of the *ſpleen*. From obſerving a large empty ſpace near the *ſpleen*, in the abdomen of a dead body, the proportional largeneſs of its blood-veſſels, and the ſtructure of the *ſpleen* analogous to that of the penis, he concludes the *ſpleen* in a living perſon to be ſubject to inflations like a bellows: but how it is thus to be moved, or to what purpoſe, he does not tell us. See Comment. Acad. Petrop. Tom. 4. p. 156. ſeq.

Mr. Lieutaud argues for the *ſpleen*'s being larger by a greater quantity of blood in it, when the ſtomach is empty, and that this blood is preſſed out, when the ſtomach is full, to increaſe the ſecretion of bile. Hiſt. de l'Acad. des Scienc. 1733.

We have an account, in the Philoſophical Tranſactions, N° 451. of the extirpation of part of the *ſpleen* of a man, which had begun to mortify; notwithſtanding which, the man recovered.

The *ſpleen* has been cut out of dogs without any damage. Mr. Boyle mentions his having ſeen the experiment tried on a young ſetter, who recovered in a fortnight. Works Abridg. Vol. 1. p. 27.

Dr. Pozzi relates the phænomena he remarked in diſſecting a dog, whoſe *ſpeen* was cut out when he was young. The liver, which was larger and more heavy than ordinary, was alſo more brittle; the vena portarum was enlarged; the gall-bladder was full of bile, more acrid than it is commonly. From theſe appearances he thinks the uſe of the *ſpleen* to be for ſeparating a liquor like to ſpittle, which may dilute the bile, and prevent its too great acrimony. Med. Eſſ. Edinb.

The uncertainty we are in, as to the real uſe of the *ſpleen*, has given ground, perhaps, to the notion that men might live without the *ſpleen*; and that, in many caſes, it might contribute much to health to cut out this uſeleſs viſcus. In the Journal des Savans, there is an account of a method of deſtroying it, without the terrors of the operation of opening the body.

This was done by a perſon who applied a wooden knife to the ſurface of the body where the *ſpleen* is lodged, and ſtriking forcibly on it with a mallet, told the patient that he had broken the ſubſtance of the *ſpleen*; and that after this it required only the taking certain medicines which he prepared, utterly to deſtroy and carry it out of the body.

The folly of a pretence of this kind, one would think, ſhould

have been alone fufficient to have laughed it out of the world; but numbers of people fubmitted to the operation, till a youth in Peterfburg unhappily being killed by a blow of the kind here mentioned; and his belly fwelling greatly, excited the curiofity of his relations to have it opened. The caufe of his death was found to be an hæmorrhage, which had filled the cavity of the abdomen, and which proceeded from the *fpleen's* having been burft by the blow. This convinced them, that attempts to wound the *fpleen* were no longer to be looked upon as the means of health. Act. Petrop. Vol. I. p. 381.

Infarction of the SPLEEN, *infarctus lienis*, a difeafe confifting in an inflation of this lax and cellulofe vifcus, owing its origin to a reftriction of the blood toward the *fplenic* branch, in which nature feems to have intended the relieving herfelf from the load of a plethora, by the difcharging a part of the mafs through the vafa brevia. *Junker's* Confp. Med. p. 194.

The *infarctus lienis* differs from an obftruction of the *fpleen*, in that this laft is a total fuppreffion of the blood in it, this only a partial one. It is too often confounded with nephritic complaints, and is indeed, in general, of the clafs of hypocondriac maladies, but only arifes from a fpecial and peculiar derivation of the blood to that one vifcus, not to any other of the circumjacent parts.

Signs of it. An *infarction of the fpleen* is difcovered by an inflation of the left fide, a little below the fpurious ribs, attended with permanent pains, but thefe not very acute, or violent: thefe complaints have frequent remiffions, feldom continuing above a day or two in the fame ftate. During the time of the fymptoms being worft, there is a difficulty of breathing, and an anxiety of the præcordia, and generally a lownefs of fpirits: to thefe it may be added, that there is ufually a dry cough, and frequent belchings.

Perfons fubject to it. Men are in general much more fubject to this difeafe than women, unlefs at the middle and more advanced periods of life, when they are more fubject to it than the men. People of a melancholic habit alfo are moft afflicted with it, and fuch as have before had hypocondriac complaints, and have been injudicioufly treated with aftringents; and all perfons of a fedentary and ftudious life, or who employ much time in thinking.

Caufes of it. Thefe are a fedentary life, and a diet of too heavy and thick a kind; an omiffion of habitual bleedings, or other evacuations, or a fuppreffion of the menftrual or hæmorrhoidal difcharges; an injudicious treatment of intermittent fevers with aftringents, or of acute ones with too cooling medicines, and an habitual coftivenefs: and to thefe may be added an hereditary difpofition.

Prognoftics in it. This is a difeafe of no immediate danger to the patient, and the more recent it is when taken in hand, the eafier it is cured; if left to itfelf it becomes habitual, and brings no danger of death with it, but if improperly treated, it frequently becomes the bafis of the moft obftinate kind of quartans, or degenerates into a fcirrhus, which may be a long time fuffered without any danger of life; but finally, the whole too often ends in flow hectic fevers, and œdematous and afcitic fwellings. In women it often terminates in a vomiting of blood; and fometimes, but very rarely, an inflammatory and fuppurating ftafis fupervenes, and a black, fetid, and purulent matter is voided by ftool or by vomiting.

Method of cure. The plethoric habit, which gives rife to this complaint, is to be taken down by copious bleedings in the right foot, and then fhould be repeated every fpring and autumn; and the menfes muft be brought to a proper regularity in the ufual way, as muft alfo the hæmorrhoids in the other fex, by the application of leeches to the part. The fpiffitude of the blood is to be amended by decoctions of elecampane, hyffop, and the like; and by moderate and repeated dofes of tartarum vitriolatum, gum ammoniacum, &c. and gentle dofes of rhubarb and fena in infufion muft be taken at times. To thefe may be added the external ufe of refolvents and ftrengthners, fuch as ointment of marfhmallows, the plaifter of gum ammoniacum, and the like; and finally, the preparations of fteel are to be given: to thefe fome add a number of things efteemed fpecifics, fuch are madder and caper roots, dodder, yarrow, white maidenhair, and fpleenwort, and the bark of the afh-tree, and wood of the tamarifk. *Junker's* Confp. Med. p. 197.

Scirrhus of the SPLEEN. This is an indurated tumor of the *fpleen*, caufed by a ftagnation and infpiffation of the humors from the exhalation of their thinner parts. This complaint is fometimes compleat, and fometimes incompleat; but in the moft favourable cafes it is a greatly more dangerous complaint than an infarction of the *fpleen*, and more difficult of cure. *Junker's* Confp. Med. p. 201.

Signs of it. Thefe are a fenfible and palpable hardnefs under the ribs on the left fide, extending toward the loins, with a fenfe of a weight, as it were, hanging in this part; and hence the lying on the right fide is always very painful and uneafy. The face has dull deadnefs in the look, which fometimes is communicated alfo to the fkin of the whole body, and there is ufually a blacknefs about the orbits of the eyes; there is alfo a fenfation of a narrownefs in the breaft, with fome difficulty of breathing, and a dry cough. The appetite is ufually voracious, but fometimes it is affected with naufeas, without any apparent caufe. The bowels are ufually fomewhat coftive, but irregularly fo. The mind alfo feems affected, and a gloomy morofenefs, filence, and anxiety, opprefs the perfon, without any vifible caufe. Finally, there ufually is a fwelling in the right foot, which by degrees extends itfelf farther, and is feldom regarded at firft.

Perfons of both fexes are equally fubject to this diforder, but it is not, however, very common. Men who have lung been fubject to hypocondriac diforders, and women fubject to hyfteric complaints, are moft fubject to it; and to thefe may be added, perfons of an indolent, fpeculative, and fedentary life, and thofe who have been imprudently treated with aftringents in intermittent cafes.

Caufes of it. Befide thofe before mentioned, a fcirrhus is fometimes brought on in the *fpleen* by a violent blow, or other external injury; a too thick diet may alfo be very inftrumental in laying the foundation for it; and not a little may be added to all thefe cafes, by violent paffions of the mind.

Prognoftics in it. In recent *fcirrhufes*, and fuch as are yet incompleat, there is fome hope of fucceeding in the attempt of a cure; and on the contrary, in old cafes and compleat *fcirrhufes*, there is indeed very little hope: but there is this comfort for the patient, that even fuch a one, when wholly left to itfelf, will remain many years without endangering life.

There is in a *fcirrhus* an eternal tendency to corruption, but this is rather to be expected from fphacelation, than from an inflammatory fuppuration; but when emollients are ufed, there is great and imminent danger: for as thefe are nearly allied to the maturating remedies, they may produce their effect; and it is certain, that no laudable fuppuration is ever to be expected in this cafe.

Method of treatment. This cafe is to be treated in the fame general manner with the infarctions of the *fpleen*, already mentioned; but the more powerful refolvents are to be ufed in this, as the more ftubborn cafe. Gentian, bryony, and arum root, with the fine aperient roots, and the capillary herbs, with the powerful gums, as galbanum, fagapenum, ammoniacum, and the reft. Bleeding muft alfo be ordered, as foon as the primæ viæ have been cleanfed; and externally the plaifter of cicuta, with ammoniacum, may be applied: but if the cafe is fixed and obftinate, it is better to let all applications alone, and leave nature to do the beft for herfelf. *Junker's* Confp. Med. p. 202.

SPLEEN, in ichthyology. The *fpleen* in fifhes is ufually fituated near the ftomach, in the left fide of the abdomen. Its figure is generally triangular, fometimes oblong. Its colour is always more dufky and obfcure than that of the liver.

SPLEEN-*wort*. See the article LONCHITES.

SPLENECTOMIA, the name given to the chirurgical operation of cutting out the fpleen. Many have thought that the fpleen was an ufelefs part of the human body, and even noxious; but this feems to be a very rafh opinion.

SPLENIA, a word ufed by furgeons to exprefs compreffes, or rags feveral times doubled, applied to wounds over the plaifters, or other dreffings.

SPLENII *inferior*, in anatomy, a name given by Cowper to a mufcle, called by Albinus *fplenicus colli*, and by Winflow, and others, *maftoidæus pofterior*, and *portio inferior fplenii*. See the article SPLENIUS.

SPLENITIS, in medicine, the name of a fpecies of fever, in which the blood is powerfully directed toward the fpleen by nature, in order to break and diffolve congeftions formed there. The *fplenitis* differs from what authors call an *infarctus lienis* in degree, as in this the blood only ftagnates in fome degree, and is not wholly obftructed; and as there is no acute inflammatory fever here, as there is in the *fplenitis*.

The *fplenitis* is very various in degree; in fome cafes the whole parenchymatous fubftance of the fpleen being affected, in others only its membranaceous and fuperficial parts. It is eafy to conceive that the former cafe is greatly the more dangerous of the two.

Signs of it. This difeafe always firft attacks people with a very remarkable fhivering and coldnefs; this is fucceeded by a very terrible heat, and intolerable thirft; and there is a preffive pain, and a fenfible fwelling in the left hypocondrium. If the patients expofe themfelves a little to the open air, the extremities grow cold almoft immediately; if a hæmorrhage happens, it is always from the left noftril: and finally, the urine is reddifh and turbid, and after the fourth day depofits a rofe-coloured fediment, which has fomewhat of the appearance of matter. Plethoric perfons are more than all others fubject to this difeafe.

Caufes of it. The general caufe is a plethora joined with a thicknefs of the blood, which forms ftafes, and fixed coagulations in the fpleen; and the fever itfelf is no other, than the attempt of nature to break through thofe ftafes, by the additional velocity of the motion of the blood. The ufual accidents that bring on this bad ftate of the blood,

are the omiffion of habitual bleedings, or the fuppreffion of the natural difcharges of the menfes or hæmorrhoids; and the occafional accidents that immediately bring on the difeafe in this ftate of the blood are, violent commotions of the mind, fudden chilling of the body when very hot, as by drinking cold water immediately after violent exercife, the taking violently aftringent medicines in fevers, and an improper ufe of cooling external remedies in diforders of the fpleen, as the infarctions of it, and the like. *Junker*'s Confp. Med. p. 292.

Prognoftics in it. It is always a very dangerous difeafe, though not fo fatal as the hepatitis, or a like inflammatory ftate of the liver; but it is remarkable, that as the vomiting a black matter in the hepatitis is always a fatal fymptom, fo in this difeafe the fame matter is frequently voided, but it is here falutary, and frequently carries off the difeafe. The appearance of the hæmorrhoids has alfo been frequently obferved to have the fame good effect. When the inflammation lies deep, it is moft frequently fatal; when it is fuperficial, it is often carried off: but when it feems cured, it fometimes is found afterwards to have degenerated into an incurable fcirrhus of the part.

Method of cure. The firft thing to be done, is to open the bowels by a clyfter, and they are afterwards to be kept from becoming coftive, by a repetition of the fame means. Bleeding is ufually neceffary, and may be performed once or more in the beginning of the difeafe; then gentle diaphoretics are to be given with juleps flightly acidulated. Thefe are the proper medicines for the morning; and in the afternoon powders of nitre, vitriolated tartar, and crabs eyes, fated with lemon juice, are to be given with the cooling emulfions; and if the pains be very violent, they may be mitigated, by giving fmall dofes of a gentle anodyne, fuch as the ftorax pill, with the beforementioned powders. If the fuppreffion of the habitual hæmorroidal evacuations are fufpected to be the caufe of the difeafe, leeches muft be applied to the parts, and no wine, or any other ftrong liquor, muft be allowed, till the decline of the difeafe. *Junker*'s Confp. Med. p. 293.

SPLENITIS is alfo ufed by fome authors to exprefs a tumor or inflammation of the fpleen.

Splenitis is alfo ufed as the name of a vein in the left hand, the fame as the *falvatella*. The vein of this kind in the right hand is called *jecoraria*.

SPLENIUS, called alfo *maftoidæus pofterior*, in anatomy, a flat, broad, oblong mufcle, fituated obliquely between the back part of the ear, and the pofterior and lower part of the neck.

It is partly fingle, and partly made up of two portions, one fuperior, the other inferior. Thefe two portions are clofely united backward, making only one plain, but they are divided above.

The fuperior portion is fixed to the extremities of the three or four loweft fpinal apophyfes of the neck, and of the firft, and fometimes the firft and fecond of the back. It is not fixed immediately to the apophyfes of the neck, which are above the laft, but only by the intervention of the pofterior cervical ligament. It is likewife fixed to the edge of the interfpinal ligaments of the other vertebræ; from thence it runs obliquely toward the maftoide apophyfis, and is inferted in its upper part, and along the neighbouring curve portion of the tranfverfe ridge of the os occipitis.

The inferior portion of the *fplenius* is fixed to three or four fpinal apophyfes of the back, beginning by the fecond or third, and afterwards running up till it reaches the fuperior and lateral part of the neck. It is inferted in the tranfverfe apophyfes of the three or four fuperior vertebræ of the neck, by the fame number of extremities a little tendinous; thefe, however, are fometimes only two in number. The two *fplenii* reprefent a great Roman V, and the *fplenius*, and fterno-maftoidæus of the fame fide, form a figure like a Roman A, or the legs of a pair of compaffes, the points of which are in an horizontal plane. *Winflow*'s Anatomy, p. 239.

SPLENIUS *capitis*, in anatomy, a name given by Albinus to a mufcle, called by Winflow, and others, the *maftoidæus fuperior*, or upper portion of the *fplenius*. Riolanus, and others, call it the *triangularis fplenii*.

SPLENIUS *colli*, in anatomy, a name given by Albinus to a mufcle, called by Winflow, and others, *maftoidæus pofterior*, or the lower portion of the *fplenius*; and by Cowper the *mufculus inferior fplenii*. See SPLENIUS, fupra.

SPLICE (*Cycl.*)—*Cut*-SPLICE, in a fhip, is when a rope is let into another with as much diftance as one pleafes, fo as to have it undone at any time, and yet be ftrong enough.

Round-SPLICE, is when a rope's end is fo let into another, that they fhall be as firm as if they were but one rope.

SPLINTERS *of bone*, in fractures. In cafes of fractures the furgeon is frequently troubled with *fplinters of the bone* in the way, which vellicate and prick the neighbouring parts, and render the proper execution of his office very difficult. If thefe *fplinters* are loofe, and have no connection with the bone, they muft be carefully lifted out of the wound; if they hang to the bone in fome part by the periofteum, that muft be cut off with the fciffors; but if they adhere pretty firmly to the neighbouring parts, and do not hinder the reduction of the bone, it is beft to replace the bone, and leave them either to loofen, and come out of themfelves by the fuppuration of the parts, or to grow again, as they fometimes will fafely and firmly do, to the reft of the bone. When they adhere pretty firmly to the principal parts of the bone, they fhould never be extracted by force, but replaced with the greateft exactnefs: for when this is properly performed, they will frequently unite to the reft of the bone.

When the points of *fplinters of bone* ftick fo far out, that they are a great hindrance to the reduction of the bone, you are diligently to confider, whether you can, by any means, contrive their reunion to the bone, which may be determined, by obferving at what diftance they are from the large bone, and what quantity of flefh there is intervening: when they cannot be reduced, or reunited to the bone, they muft be removed with a pair of ftrong forceps, or, if they ftick very firmly, with a fine faw. If the *fplinters* are buried under the fkin, and cannot be got at with hands, it is proper firft to try if they can be reduced to their natural fituation; and if they cannot, an incifion muft be made through the fkin, that they may be taken out. *Heifter*'s Surg. p. 109.

SPLIT, in botany, a name given by fome authors to the great *fumaria bulbofa*, or hollow root. *Rupp.* Flor. Sen. p. 216.

SPLIT, at fea. When a fail is blown to pieces, the feamen fay it is *fplit*.

SPLITTING. To *fplit* a thin piece of metal, as an old filver groat, place the metal on the heads of three pins ftuck up triangularly, and let a heap of flower of brimftone burn out upon it; then throwing it hard againft the floor, the upper part will feparate from the lower. *Boyle*'s Works Abr. Vol. I. p. 134.

SPOLIARIUM, among the antient Romans, the third part of the bath, ufed for undreffing and dreffing in. *Pitifc.* Lex. Ant. in voc.

Spoliarium was likewife a part of the gladiatorial fchools, where their cloths and ornaments were laid, and where the wounded and killed were carried. *Pitifc.* l. c.

SPONDIAS, in botany, the name given by Linnæus to the genus of plants, called by Plumier *monbin*; the characters are thefe. The perianthium is plain and permanent, and confifts of one leaf, divided into five fegments at the edge. The flower is compofed of five oval and expanded petals. The ftamina are nine filaments, five of which are placed in a circle, the others are of the fame length with thefe, which is that of the cup. The antheræ are fimple. The germen of the piftil is oval. The ftyle is very fmall, and is terminated by three obtufe and permanent ftigmata. The fruit is an oval berry in every cell, of which there are contained four nuts. *Linnæi* Gen. Plant. p. 175. *Plumier*, Gen. 22.

SPONDYLI, Σπονδυλοι, in antiquity, pellets of brafs ufed in giving fentence, before the κυαμοι, or beans, came into ufe. *Potter*, Archæol. Græc. Tom. I. p. 119.

SPONDYLOLITHOS, a name given by authors to a ftone found in the country of Tyrol, and elfewhere, refembling the vertebræ of an animal. It is in reality no other than the vertebræ of fome fea-fifh petrified, as is common with us.

SPONDYLUS, in natural hiftory, a name given by authors to a kind of oifter of an oblong and umbonated form, of which there are feveral fpecies. See OSTREA.

SPONGIA, *fpunge*, in botany, the name of a genus of plants, the characters of which are thefe: that it is foft and elaftic, naturally growing under water, and pervious by multitudes of holes.

The fpecies of *fpunge*, enumerated by Mr. Tournefort, are thefe. 1. The fineft *fpunge* with very fmall cavities. 2. The great flatted *fpunge*. 3. The globular, or round *fpunge*. 4. The funnel-fafhioned *fpunge*. 5. The cup-like *fpunge*, divided into fegments at the edges. 6. The branched *fpunge*. 7. The conic-fhaped branched *fpunge*. 8. The fhrubby-branched *fpunge*. 9. The branched river-*fpunge*. 10. The hairy *fpunge*. 11. The fail *fpunge*. 12. The tubular long American *fpunge*. 13. The very long-branched rope-like American *fpunge*. 14. The headed and fingered American *fpunge*. 15. The American honeycomb *fpunge*. 16. The flatted and elegantly punctuated American *fpunge*. *Tourn.* Inft. p. 575.

Burnt *fpunge* is much recommended as a fweetner of the blood, and a diuretic. Some have pretended to cure the leprofy with it, and others extol it againft the bite of a mad-dog; but thefe are virtues not univerfally received.

SPONGIOLI, a word ufed by fome authors to exprefs the fmall button mufhrooms, which are gathered before they expand or open their heads.

SPONSUS, one of the many names given by the chemifts to mercury.

SPORADIC *difeafes*, diftempers which feize particular perfons at any time or feafon, or in any place. They are thus called, in contra-diftinction to the epidemic difeafes, which are peculiar to certain times and feafons, or to peculiar places.

SPORTS, in the customs of Flanders, were in great vogue through Flanders and the Low-Countries, some centuries ago. Every city had a solemnity of this kind peculiar to itself: thus Bruges had that called the *Forester*; Valenciennes the *Prince of Pleasantry*, and the *Prince of the Horse-comb*; Cambray the *King of Ribaldry*; and Bouchain the *Provost of Sots*. Lisle, one of the richest towns in Flanders, was not behind hand with its neighbours in celebrating *sports*, by the magnificence and diversions whereof, to draw together a vast concourse of people from all parts. One of the chief of these divertisements was called the *King of the Spinet*, *Roy d'Epinette*; which was celebrated with a great deal of pomp and shew. See Hist. Acad. Inscript. Tom. 4. p. 452, seq.

SPOT (*Cycl.*)—SPOT, in ornithology, the name of a particular species of pigeon, called by Moore the *columba maculata*. It is of the size of a small common pigeon, and was brought over to England from Holland. This species has always a *spot* upon its head, just above its beak, from whence it has its name. The feathers of the tail are always of the same colour with this *spot*, and the rest of the body is all white. The *spot* and tail are black in some, red in others, and yellow in others. They look very beautiful when they spread their tails and fly, and are a distinct species, as they always produce young ones of their own marks. *Moore*'s Columb. p. 44.

SPRING, (*Cycl.*) in mecanics, is used to signify a body of any shape, perfectly elastic.

Length of a SPRING may, according to its etymology, signify the length of any elastic body, but it is particularly used by Dr. Jurin to signify the greatest length to which a *spring* can be forced inwards, or drawn outwards, without prejudice to its elasticity. He observes this would be the whole length, were the *spring* considered as a mathematical line; but in a material *spring*, is the difference between the whole length, when the *spring* is in its natural situation, or the situation it will rest in when not disturbed by any external force, and the length or space it takes up when wholly compressed and closed, or when drawn out.

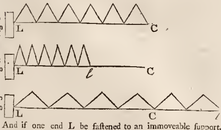
Strength, or *force of a* SPRING, is used for the least force or weight, which, when the *spring* is wholly compressed or closed, will restrain it from unbending itself. Hence also the force of a *spring* bent, or partly closed, is used for the least force or weight, which, when the *spring* is bent thro' any space less than its whole length, will confine it to the state it is then in, without suffering it to unbend any farther.

The theory of *springs* is founded on this principle, *ut tensio, sic vis*; that is, if a *spring* be forced or bent inwards, or drawn outwards, or any way removed from its natural situation, its resistance is proportional to the space by which it is removed from that situation.

This principle was verified by the experiments of Dr. Hook [b], and since him by those of others, particularly by the accurate hand of Mr. George Graham.—[[b] Lectures *de potentia restitutiva*, 1678.]

For the better in elligence of this principle, on which the whole theory of *springs* depends, suppose a *spring* C L resting with the end L against any immoveable support, but otherwise lying in its natural situation, and at full liberty; then if this *spring* be pressed inwards by any force *p*, or from C towards L, through the space of one inch, and can be there detained by that force *p*, the resistance of the *spring*, and the force *p*, exactly counterballancing one another; then will the force 2 *p* bend the *spring* through the space of two inches, 3 *p* through three inches, 4 *p* through four inches, &c. The space C *l* (Fig. 2.) through which the *spring* is bent, or by which its end C is removed from its natural situation, being always proportional to the force which will bend it so far, and will detain it so bent.

Fig. 1.
Fig. 2.
Fig. 3.



And if one end L be fastened to an immoveable support, (Fig. 3.) and the other end C be drawn outwards to *l*, and be there detained from returning back by any force *p*, the space C *l*, through which it is so drawn outwards, will be always proportional to the force *p*, which is able to detain it in that situation.

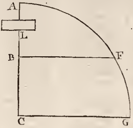
And the same principle holds in all cases, where the *spring* is of any form whatsoever, and is in any manner whatsoever forcibly removed from its natural situation.

It may be here observed, that the *spring*, or elastic force of the air, is a power of a different nature, and governed by different laws from that of a material *spring*. For supposing the line L C (Fig. 1.) to represent a cylindrical volume of air, which by compression is reduced to L *l*, (Fig. 2.) or by dilatation is extended to L *l*, (Fig. 3.) its elastic force will be reciprocally as L *l*; whereas the force, or resistance of a *spring*, will be directly as C *l*.

This principle being premised, Dr. Jurin gives us a general theorem concerning the action of a body striking on one end of a *spring*, while the other end is supposed to rest against an immoveable support. And lest any objection should be formed against the possibility of an immoveable support, since any body, how great soever, may be moved out of its place by the least force, he observes, that the objection may easily be removed. Thus, if the *spring* L M be supposed continued to N, so that L N = L M, if a body M, with any velocity in the direction M L,

strikes one end of the *spring*, and a body N, at the same time, with an equal velocity, and a contrary direction, N L strikes the other end N of the continued *spring*, the point L, the end of the first supposed *spring* will be immoveable.

Theorem. If a *spring* of the strength P, and the length C L, lying at full liberty upon an horizontal plane, rest with one end L against an immoveable support; and a body of the weight M, moving with the velocity V, in the direction of the axis of the *spring*, strike directly on the other end C, and thereby force the *spring* inwards, or bend it through any space C B; and a middle proportional C G be taken between the line $C L \times \frac{M}{P}$, and 2 *a*, *a* being the height to which a heavy body would ascend in vacuo with the velocity V; and upon the radius R = C G be erected the quadrant of a circle G F A: then,



1°. When the *spring* is bent through any right line of that quadrant, as the body M, is to be C B, the velocity *v* of the original velocity V, as the cosine to the radius; that is, $v = V \times \frac{BF}{R}$.

2°. The time *t* of bending the *spring* through the same sine C B, is to T the time of a heavy body's ascending in vacuo with the velocity V, as the corresponding arch to 2 *a*; that is, $t = T \times \frac{GF}{2a}$.

The doctor gives a demonstration of this theorem, and deduces a great many curious corollaries from it. These he divides into three classes. The first contains such corollaries as are of more particular use when the *spring* is wholly closed, before the motion of the body ceases.

The second comprehends those relating to the case, when the motion of the body ceases before the *spring* is wholly closed. And

The third, in case the motion of the body ceases at the instant that the *spring* is wholly closed.

We shall mention some of the last class, as the most simple; having first premised, that P = strength of the *spring*, L = its length, V = the initial velocity of the body closing the *spring*, M = its mass, *t* = time spent by the body in closing the *spring*, A = height from which a heavy body will fall in vacuo in a second of time, *a* = the height to which a body would ascend in vacuo with the velocity V, C = the velocity gained by the fall, *m* = the circumference of a circle, whose diameter is 1. Then,

1°. If the motion of the body striking the *spring* cease, when it is wholly closed, the initial velocity V is equal to $C\sqrt{\frac{PL}{2MA}}$.

2°. The initial velocity V is proportional to $\sqrt{\frac{PL}{M}}$.

3°. If P L be given, either in the same or in different *springs*, the initial velocity V is reciprocally as $\sqrt{M}$.

4°. The product of the initial velocity, and the time spent in closing the *spring*, or V *t* is equal to $1'' \times \frac{m\,CL}{4A}$; and is proportional to L the length of the *spring*.

5°. The initial quantity of motion, or M V, is equal to $C\sqrt{\frac{PLM}{2A}}$.

6°. M V is proportional to $\sqrt{PLM}$, or to P *t*. And if P L be given, either in the same or different *springs*, M V is as $\sqrt{M}$.

7°. If $\frac{P}{L}$ be given, either in the same or in different *springs*, the initial quantity of motion is as the length of the *spring* into the time of bending it.

8°. If a quantity of motion M V bend a *spring* through its whole length, and be consumed thereby, no other quantity

quantity of motion equal to the former, as $n M \times \frac{V}{n}$, will close the same *spring*, and be wholly consumed thereby.

9°. But a quantity of motion, less or greater than M V, in any given ratio, may close the same *spring*, and be wholly consumed in closing it; and the time spent in closing the *spring* will be respectively less or greater, in the same given ratio.

10°. The initial *vis viva*, or $M V^2$, is equal to $\frac{C^2 P L}{2 a}$; and $2 a M = P L$.

11°. The initial *vis viva* is as the rectangle under the strength and length of the *spring*; that is $M V V$ is as P L.

12°. If $\frac{P}{L}$ be given, the initial *vis viva* is as P^2, or as L^2.

13°. If the *vis viva* $M V^2$ bend a *spring* through its whole length, and be consumed in closing it; any other *vis viva*, equal to the former, as $n n M \times \frac{V^2}{n n}$ will close the same *spring*, and be consumed thereby.

14°. But the time of closing the *spring* by the *vis viva* $n n M \times \frac{V^2}{n n}$, will be to the time of closing it by the *vis viva* $M V^2$, as n to 1.

15°. If the *vis viva* $M V^2$ be wholly consumed in closing a *spring* of the strength P, and length L; then the *vis viva* $n n M V^2$ will be sufficient to close, 1°. either a *spring* of the strength $n n$ P, and length L. 2°. Or a *spring* of the strength n P, and length n L. 3°. Or of the strength P, and length $n n$ L. 4°. Or if n be a whole number, the number $n n$ of *springs*, each of the strength P, and length L, one after another. We may add, that it appears from hence that the number of similar and equal *springs* a given body in motion can wholly close, is always proportional to the squares of the velocity of that body. And it is from this principle that the chief argument, to prove the force of a body in motion to be as the square of its velocity, is deduced. See FORCE, *Appendix*.

The theorem abovementioned, and its corollaries, will hold equally, if the *spring* be supposed to have been at first bent through a certain space, and by unbending itself, to pass upon a body at rest, and thereby to drive that body before it, during the time of its expansion: only V, instead of being the initial velocity with which the body struck the *spring*, will now be the final velocity, with which the body parts from the *spring* when totally expanded.

It is also to be observed, that the theorem, &c. will hold equally good, if the *spring*, instead of being pressed inward, be drawn outwards by the action of the body. The like may be said, if the *spring* be supposed to have been already drawn outwards to a certain length, and in restoring itself draw the body after it. And lastly, the theorem extends to *springs* of any form whatever, provided L be the greatest length it can be extended to from its natural situation, and P the force which will confine it to the length. See Phil. Transf. N° 472. sect. 10.

SPRING, in natural history. Nothing is more certain, than that some *springs* wholly owe their origin to rains, though this is not the case with others. Those intermitting *springs*, which flow very largely after great rains, and then are gradually dried up, are owing wholly and entirely to rains; but those are not the only ones, but some of the perennial *springs*, which run in summer as well as winter, and in dry as well as wet seasons, are owing also to rains or vapours of a like kind: thus those *springs*, found at the tops of mountains, seem to be owing to the thick mists which we every day see hanging about the top of those mountains.

Though some *springs* are thus evidently owing to rain and vapours, yet others are plainly of some very different origin. The temporary *springs*, or irregular fountains we find in many parts of the world, cannot come from rains or dews, much less can those regular periodic fountains, of the nature of the Zirchnitzer sea in Carniola, and the fountain of Loire in France, and that of Lambsbourne in England: and it is yet less possible, that such vast perennial *springs*, as those of Wellowbridge in our kingdom, and of the Sorgue in France, can come from rains; for all the water that falls in the whole country about these places, in rains and dews, is not nearly so much as that which issues from them. *Plot*, de Origin. Font.

It is said [b] that in the diocese of Paderborn, in Westphalia, there is a *spring* which disappears twice in twenty four hours, and always returns at the end of six hours with a great noise, and with so much force, as to turn three mills not far from its source. It is called the *bolder-born*, or boisterous *spring*.—[b Philos. Transf. N° 7. p. 127.]

Burning, or *Boiling* SPRINGS. The *burning spring* near Grenoble in Dauphine is famous: St. Augustin speaks of it as extinguishing lamps which are lighted, and lighting those which are extinct [c]. But it is now cold like others; only near it is a spot of ground, which still emits a light flame; over which some imagine it might antiently have passed [d].—[c *August*. de Civ. Dei, lib. 21. cap. 7. & 11. Mem. Acad. Inscipt. Tom. 9. p. 565. d Mem. Acad. Scien. An. 1699. p. 26.]

At Bosely, near Wenlock in Shropshire, there is a famous boiling well, which was discovered, in June 1711, by an uncommon noise in the night, so great, that it awakened several people, who being desirous to find what it was owing to, at length found a boggy place under a little hill, not far from the Severn; and perceiving a great shaking of the earth, and a little boiling up of water through the grass, they took a spade, and digging up some part of the earth, the water flew to a great height, and was set on fire by a candle. This water was for some time afterwards constantly found to take fire, and burn like spirit of wine; and after it was set on fire, it would boil the water in a vessel sooner than any artificial fire, and yet the *spring* itself was as cold as any whatever. Phil. Transf. N° 334.

This well was at length lost for many years, and not recovered till May 1746, when by a rumbling noise under ground, like to what the former well made, it was hit upon again, though in a lower situation, and thirty yards nearer the river.

The well is four or five feet deep, and six or seven wide; within that is another less hole of like depth, dug in the clay, in the bottom whereof is placed a cylindric earthen vessel, of about four or five inches diameter at the mouth, having the bottom taken off, and the sides well fixed in the clay, rammed close about it. Within the pot is a brown water, thick as puddle, continually forced up by a violent motion, beyond that of boiling water, and a rumbling hollow noise, rising and falling by fits five or six inches. It may be fired by a candle at a quarter of a yard distance; and it darts and flashes in a violent manner, about half a yard high. It has been left burning forty eight hours, without any sensible diminution. It may be extinguished by putting a wet mop upon it, which must be kept there a small time. On the removal of the mop there succeeds a sulphureous smoke, lasting about a minute, and yet the water is very cold to the touch. Phil. Transf. N° 482. sect. 6.

Lancarim SPRING. See the article LANCARIM.

SPRING-*arbor*, in a watch, that part in the middle of the *spring*-box, about which the *spring* is wound or turned, and to which it is hooked at one end.

SPRING-*box*, in a watch, the cylindrical case, or frame, that contains within it the *spring* of the watch.

SPRINGER, in ichthyology, a name given by authors to the grampus, or arca.

SPRINGES, (*Cycl.*) a sort of horsehair nooses, made so as to run very easy, and planted in the places where birds run in some particular path, to take them as they pass.

Those birds that frequent the waters, or love to paddle and feed in wet and plashy places, are the most easily taken by these *snares*.

The sportsmen who would use them to advantage, must first carefully search out the haunts and places where the fowls come in flocks, or in couples, and feed in the morning and evening hours. The furrows and water-tracks in these places are principally to be regarded; and wherever the several furrows, or water-courses, meet in one, and afterwards divide into several others, these places are to be remarked above the rest: the places which have most marks of the birds feet, give also the surest of all proofs, that they are well frequented. When these places are found, there should be placed a number of small and short sticks crosswise overthwart all the other passages, one stick being placed about half an inch from another, and making together a kind of fence, guarding every way, except that one through which it is intended the fowls should pass. This being done, a good stiff stick is to be provided, cut flat on each side; both ends of this stick are to be planted under water, so that the upper part of the flat side may only be upon a level with the surface; then a bow is to be made of a hazel, or willow, in the form of a pear, broad and round at one end, and narrow at the other, and at least a foot long, and five or six inches wide; at the narrow end of this there is to be a nick or dent. Then a stiff young grown plant of hazel, elm, or withy, is to be chosen, being bushy and clear, and without knots, three or four inches about at the bottom, and about an inch at the top. Having made the bottom end of this sharp, at the top of it there must be fastened a very strong loop, made of about an hundred horsehairs, platted very fast together with strong packthread, and made to slip any way with great ease. This noose or loop should be just of the dimensions of the pear-fashioned loop before mentioned. Then hard by this loop, and within an inch of the end of the plant, there is to be fastened with strong horsehair a broad and thin trigger, made sharp at both ends. Then the bigger sharp end of the plant being made fast in the ground, just by the edge of the water; the smaller end, with the loop and the trigger, must be brought down just to the first bridge; and the pear-fashioned hoop being set upon the bridge, one end of the trigger must be set upon the nick in the hoop, and the other end on the nick

ftick made on the fmall end of the plate, which by the violence and bend of the plant will make them all ftick together till the hoop be removed. This done, the loop is to be laid upon the hoop in fuch fafhion as the hoop is proportioned: then from each fide of the hoop little fticks are to be pricked, as before directed, making as it were a kind of impaled path-way, widening it all the way as it goes farther from the hoop, and making it fo confiderably wide at the end, that any fowl that chances to come that way may be entered a confiderable way in, before fhe perceives the fence; by this means the bird will be enticed to go ftrait on to the *fpringe*, and as foon as fhe touches it, either with head or feet, fhe will be certainly caught; and thus if the plant be ftrong enough, the largeft bird may be caught as eafily as the leaft.

When the fmaller fowls, that frequent watery places, are to be taken by this engine, it is to be made only a great deal flighter. When it is intended for fnipes, woodcocks, or the like, the main plant may be of willow, hazel, or grown ozier, or any other pliant wood that will eafily bend, and will recover its ftraitnefs again. The ufe of this engine is limited to the winter-feafon, and to times when there is much wet upon the ground. If there happen any great frofts, fo that there is no advantage to be made of the wet places firft defcribed, then the fportfman is to look for fome place where there is a confiderable fall, and where the current is not frozen, and in this place the *fpringes* are to be fet; and the greater the frofts are in this cafe, the more birds there will be taken.

There is another ufe of *fpringes* for birds, which is the taking, by means of them, certain birds on the boughs of trees and in hedges, which is often attended with very great fuccefs. The fportfman, for this purpofe, muft firft mark fome tree where the birds very much refort; then fix on fome particular branch that is tolerably ftrait, and cutting off all the twigs to within a foot or two of the top, he is there to bore a hole through the branch with a piercer or wimble, large enough to admit a goofe-quill. Then another branch is to be pitched upon, at about a foot diftance from the firft, and all its boughs are to be pared away up to a certain height. There is to be fixed to this branch a packthread of half a foot long, and at the end of this is to be tied a noofe of plated horfehair. The branch to which the packthread is faftened, is then to be ftooped fo far, that the noofe may be brought through the hole in the other branch, and faftened there by means of a little ftick four fingers long, and hooked at the end, juft fitting the hole, and fo brought into it, as juft to ftop the flying back of the other branch. Then there is to be placed beyond the noofe fome bait of a fruit, or infect, as a cherry, a pear, or a worm, or any other thing which the bird, intended to be taken, is known to be fond of: this is to be fet in fuch a manner, that the bird can no way get at it but by fetting its feet on the fmall ftick which fupports the noofe, and ftops the hole. The weight of the bird will throw down the ftick, and the bird will then be caught by the legs, and tied faft to the branch where the hole is, by the flying back of the other branch where the packthread is faftened.

There is yet another method in ufe for the taking many kinds of birds, from the partridge or pheafant to the blackbird. This is made in the following manner, and is to be placed either on the ground, or on a tree, bufh, or hedge, according to the nature of the bird intended to be taken by it. A ftrait and even piece of willow, or fallow, is to be chofen, of about fix feet long, and of the thicknefs of a walking cane; this is to be fharpened at one end, and ftuck down into the ground, and at the other end there is to be faftened a fmall crook; then two holes are to be made in the ftick, the one big enough to admit a goofe-quill, the other fmaller; and a piece of ftick is to be chofen, which being bent will fpring back to its ftraitnefs again, fuch as holly, or the like: this fhould be about three feet long, and the larger end of it is to be fixed in the larger hole of the firft ftick; the fmaller end muft have faftened to it a packthread, at the end of which there is a noofe of horfehair: this is to be brought through the fmaller hole, and be pegged in fo flightly, as juft to prevent its flying back of itfelf. Then the *fpringe*, or noofe, is to be fpread on the peg, and a bait, proper for the bird intended to be taken, is to be placed at a proper diftance; fo that the bird cannot come at it but by treading on the peg, which will give way under its weight, and the ftick, to which the packthread is faftened, will fly back, and the bird will be confequently caught in the noofe, and have its legs drawn clofe to the other ftick.

SPRINGING *a leak*, at fea, is faid of a fhip that begins to leak. See the article LEAK.

SPROD, among the fifhermen of many parts of England, a name given to the falmon while in its fecond year's growth. *Willughby*, Hift. Pifc. p. 189. See the article SALMON.

SPULLERS *of yarn*, in our old writers, perfons that work at the *fpole*, or wheel. It alfo denotes triers of yarn, to fee if it be well fpun, and fit for the loom. *Blount*.

SPUN-*hay*, in the military art, hay twifted in ropes, very hard, for an expedition in the winter-time; each trooper carrying as much as he can behind him.

SPUNGE, (*Cycl.*) *fpongia*, in botany. See the article SPONGIA.

This fpecies of fea plant, when burnt, yields the fame fmell with hair or horns, or other parts of animal bodies.

A pound of *fpunge* when weighed in a humid feafon, on drying carefully in a ftove without injuring its texture, will be reduced to eleven ounces. This quantity being diftilled by the retort in the common way, and the principles feparated, and the falt and fpirit rectified, there will be found an ounce and half of a reddifh phlegm, or a fpirit fo weak, as fcarce to afford any fmell or tafte; an ounce and half of a volatile urinous fpirit; and an ounce, four drachms and a half of a volatile urinous falt; half an ounce of a fetid thick oil; half an ounce of a fix'd falt, which, befide the common lixivial alkali, contains fome fea falt; and five ounces of a caput mortuum, in which the magnet difcovers fome particles of iron.

The weight of all thefe amounts to that of the dried *fpunge* put in, within three drachms, which is a moderate lofs from evaporation, and from fome little remains which will always ftick to the veffels. By this analyfis we find, that *fpunge* gives nearly as much volatile falt as raw filk, which yields the moft of any known animal fubftance; and the difference between the quantity, yielded by that fubftance and this, is not more than four grains from the ounce. Mem. Acad. Par. 1706.

A wet *fpunge* applied to bleeding-veffels, has been found a very fuccefsful method of ftopping the effufion of blood. Vid. Phil. Tranf. Nº 478. p. 33.

Cotton-SPUNGE, a name given by fome writers to a fpecies of fea *fpunge* very fine and light, and refembling cotton in its texture. It is found at confiderable depths, growing on the rocks in form of a coarfely-branched fhrub; it is of a greyifh colour, and very flexile; but it is often rendred coarfe and rigid, by being covered in certain parts with that fort of tartarous, or cruftaceous fubftance, which fome of the antients have defcribed under the name of an *alcyonium*, and others of an *adarce*, and which the druggifts of the late ages have taught us to call *lapis fpongiæ*, the *fpunge*-ftone. It is formed itfelf of bundles of fibres, and though it has the appearance of a very open texture, yet it admits the water but very badly, and does not imbibe it in any thing like the quantity that the common *fpunge* does, nor is it, when imbibed, fo eafily preffed out again.

When examined by the microfcope, this plant appears not at all of the ftructure of the common *fpunge*, but feems a mere affemblage of oblong and flender fibres, like thofe of cotton or wool, not hollow, and very clofely amaffed together: thefe are not capable of imbibing any other moifture than the little that can get between their interftices in the mafs, and the yet much fmaller quantity that can enter the fubftance of the filaments themfelves. Hence it is no wonder, that this plant will not imbibe water fo readily as the common *fpunge*, or retain it fo well when imbibed, and yet will not yield fo to the preffure of a hand, as to part with it as that does.

The *fpunge*-ftone, or tartarous incruftation on this plant, when examined by the microfcope, is found to be very like the incruftations of ftony or fparry matter upon fticks and fhells, in fome of thofe waters which we call *petrifying fprings*, for the whole thicknefs of it is compofed of feveral thin laminæ; but then, as in thofe incruftations, each of thefe laminæ is of one fimple piece, and generally of a tranfverfely ftriated texture. In the *fpunge*-ftone each lamina is not thus ftriated, nor is indeed of one piece, but is a congeries of numbers of fimple fmall cakes, refembling the fcales of fifhes. *Marfigli*, Hift. Phyf. de la Mer.

Loaf-SPUNGE, in natural hiftory, a name given by authors to a peculiar fpecies of *fpunge* of the marine kind. It is called by the French *eponge en mie de pain*.

It grows at confiderable depths to the rocks among coral, and other fea plants. Its fhape is ufually that of a common loaf, and its texture very much refembles that of the crumb of bread. It is very various in colour at different times, being ufually of a fine fcarlet; fometimes, however, it is purple, fometimes of a violet colour, and fometimes fnow white, but this more rarely than of any other colour. It is the fofteft and lighteft of all the *fpunge*-kind, being better fuited to imbibe the water than any other. It would be greatly efteemed for the common ufes of *fpunge*, if it were produced in plenty enough to be had on the common occafions, but it is fcarce. When examined by the microfcope, it is found to be compofed of an almoft infinite number of cavities and protuberances, and is compofed of an infinite fucceffion of fmall fibres, which are arranged in a very beautiful manner, and feem held together by a fort of glutinous matter. *Marfigli*, Hift. Phyf. de la Mer.

SPUNGE, in the manege, is the extremity, or point of a horfe's fhoe that anfwers to the heel of his foot; upon it the calkins are made. Thick *fpunge* ruins the horfe's heels, and therefore ought never to be ufed.

SPURGE,

SPURGE, in botany, the Englifh name of the *tithymalus.* See the article TITHYMALUS.

This plant abounds in a thin and fharp milky juice. On being wounded, it throws this out freely. It is clammy between the fingers, and though perfectly white when firft let out, it turns bluifh, on being held a while upon a knife or lancet, and has the colour and confiftence of blue fkimmed milk. If it be made up into cakes with flower, it feems greafy or oily, and never dries. Moft of the milky juices of plants, as thofe of the wild lettuce, throatwort, and the like, readily break into curds and whey on being expofed to the air; and in the firft of thefe, the whey is of a fine purple colour. The *fpurge* juice requires a long time ftanding before it breaks, but at length it feparates, and the curd is tough and firm, and the whey clear as rock water. The whole is very corrupt and ftinking at this time, and if the cake of curd be dried, it feems a fort of refin, and will break and burn like refin at a candle.

SPURGE-*laurel.* See the article LAUREOLA.

SPURGE-*root,* in the materia medica. See the article ESULÆ *radix.*

SPURKETS, in a fhip, the fpaces in her fide betwixt the upper and lower futtocks, or betwixt the rungs fore and aft.

SPURRE, in zoology, a name given by many to the bird more commonly called the *fea-fwallow,* and by authors *ftema. Ray*'s Ornitholog. p. 269. See the article STEMA.

SPURRY, in Latin *fpergula,* is fown in the Low-Countries twice in a fummer. The firft fowing is in May; thefe plants flower in June and July, and the feed is ripe in Auguft. The fecond time of fowing it is after the rye-harveft; they ufually plow up the rye-grounds, and fow them with this feed to ferve the cows in winter, when the other forts of grafs are low or dead. The cows that feed on this plant are found to yield better milk, and finer butter is made from it, than from that of cows feeding on any other pafture. Poultry alfo are very fond of eating this plant, and the farmers in fome places have an opinion, that it makes them lay the more eggs. *Mortimer*'s Hufbandry, p. 43.

SPYRUS, the *dung of goats.* This is ufually found in fmall round maffes, and is recommended by Hippocrates as a fumigation in difeafes of the womb.

SQUACCO, in zoology, the name of a large bird of the heron kind. Its head and neck are variegated with black, white, and yellow, and it has on the back part of its head a cruft of the fame colour. Its back is of a ferrugineous yellow; its breaft and belly are white, as are alfo its wings and tail, at leaft in great part; and its legs are green. It is a bold and fierce bird. *Aldrovand.* de Avib. p. 400.

SQUAIOTTA, in botany, the name of a bird of the heron kind. Its beak is yellow, but blackifh at the extremity; its legs are green; its head is variegated with grey and black; and its back very elegantly with white and red. It feems to have had its name from its note, which it often repeats in flying. *Aldrovand.* de Avibus.

SQUALIUS, in ichthyology, a name given by Pliny to the chub. Varro, and others of the old writers, have called it *cephalus* and *fqualus,* and the Italians at this time call it *fquaglio;* it is wrong, however, to adapt any generical name to a fifh, which is itfelf but a genuine fpecies of an already eftablifhed genus. This is properly a fpecies of the cyprini, and is mentioned as fuch by Artedi.

SQUALLEY, a note of faultinefs in the making of cloth. 43 Eliz. cap. 10. *Blount, Cowel.* See REWEY.

SQUALUS, in the Linnæan fyftem of zoology, the name of a diftinct genus of fifhes, of the general order of the chondropterygii. The characters of this are, that the body is oblong, and the apertures of the gills are five on each fide. Of this genus are the galeus, lamia, zygæna, &c. *Linnæi* Syft. Nat. p. 52.

The characters of this genus, according to Artedi, are thefe. The foramina, or apertures of the bronchia, are five on each fide, and they are placed longitudinally from the head to the pectoral fins; the head is depreffed; the body oblong, and either rounded, or longifh and angular; the fkin is rough; the eyes are placed at the fides of the head; and the upper part of the tail is longer than the under. The mouth in moft of the fpecies is placed in the under part of the head, and opens tranfverfely. The fpecies of this genus are thefe.

Of thofe which have granulous teeth are the following. 1. The *fqualus* with a long-pointed and bony fnout, flatted and denticulated at each fide. This is the *priftis,* or fawfifh. 2. The fmooth *fqualus* with granulous teeth. This is the *galeus lævis,* or fmooth hound-fifh.

Of thofe which have fharp teeth, and a prickly back, the following are the fpecies. 1. The *fqualus* with no pinna ani, and with a rounded body. This is the *galeus acantheus* of authors, or the prickly dog-fifh. It has three rows of teeth on each fide. 2. The *fqualus* with no pinna ani, with the noftrils placed at the extremity of the fnout. The back of this is flat, and the belly rough and brown. 3. The *fqualus* with no pinna ani, and with a triangulate body. This is the *centrine* of authors. This has three rows of teeth in the upper jaw, and only one row in the under. 4. The *fqualus* with no pinna ani, and with the mouth placed at the end of the head. This is the *fquatina* of authors, the monkfifh, or angel-fifh, by fome called the *mermaid.* It has three rows of teeth in each jaw, the whole number amounting to one hundred and eighty, or thereabout.

Of thofe *fquali* which want the pinna dorfi, the following are the fpecies. 1. The *fqualus* with a broad and tranfverfe head, fhaped like a hammer. This is the *zygæna* of authors, the balance-fifh, or hammer-headed fhark. This has three or four rows of teeth in the jaws, and oblong holes near the eyes. 2. The *fqualus* with a tail longer than the whole body. This is the fifh called by authors the *vulpes marinus.* The tail is falcated, and refembles a fword in fome degree. 3. The *fqualus* with the noftrils placed near the mouth, and with two fmall foramina near the eyes. This is the *galeus canis* of authors. It is called in Cornwall a *tope.* It grows to five feet long, and weighs an hundred pounds. 4. The *fqualus* of a reddifh variegated colour, with the pinna ani at a middle diftance between the anus and the fin of the tail. This is called the *catulus major,* and in England the *bounce.* 5. The *fqualus* with the variegated back, and with the belly fins growing together. This is the *catulus minor* of authors, and is called the *rough hound,* or the *mergay.* 6. The grey *fqualus* with the ventral fins not joined together. This is the *catulus maximus* of authors. 7. The *fqualus* with a triangular hollow in the extremity of the back, and no foramina about the eyes. This is the *galeus glaucus* of authors, or the new fhark. 8. The *fqualus* with a flat back, and with numerous teeth ferrated at the edges. This is the *canis carcharias,* or common fhark. It is the largeft of all the *fquali,* often growing to fuch a fize, as to weigh a thoufand pounds. The fnout is long. The teeth are for the moft part ferrated, and there are fix rows of them above, and as many below, though fometimes they are fewer. The two backfins are placed, one in the middle of the back, the other very near the tail. The fkin is rough. *Artedi* Gen. Pifc. p. 44.

SQUALUS is alfo a name given by Varro, Columella, Salvian, and others, to a fpecies of the cyprinus, diftinguifhed by Artedi by the name of the oblong *cyprinus* with long fcales, and with the pinna ani containing eleven rays, and commonly known with us under the name of the *chub,* or *chevin.* The generality of authors call it *capito* and *cephalus,* but it is very improper to give diftinct generical names to fifh, which are genuine fpecies of other genera.

The name *fqualus* is originally Latin; it is ufed by Pliny, and many other of the old Roman authors, and is derived from the word *fqualor,* becaufe this fifh is found to delight in impure and dirty places.

SQUAMIS, in ichthyology, a name given by Albertus, and others, to the fifh called by us the *monk,* or *angel-fifh,* by the generality of authors *fquatina,* and by the old Greek writers *rhine.*

It is a fpecies of the fqualus, and is diftinguifhed by Artedi by the name of the *fqualus* with the mouth at the end of the fnout. See SQUATINA.

SQUAMMOSE-*culm.* See the article STALK.

SQUAMMOSE-*root,* among botanifts, one compofed of, or covered with leffer flakes. See ROOT.

SQUARE (*Cycl.*)—SQUARE, in glafs-making, an inftrument with which the conciator, or founder, ftirs and mixes together the metal when in fufion in the melting-pots. When this inftrument is grown red-hot, it is always to be quenched in a pail of water, otherwife the metal will ftick to it. *Neri*'s Art of Glafs, p. 240.

SQUARE, in the manege, is ufed for working in a *fquare.* The pifte or tread of a volt, inftead of being always circular, and traced upon a circumference round a center, ought to be imagined as if it formed four ftraight equal lines laid in a *fquare,* and equally removed from the center, or the pillar, which reprefents it in the middle of the manege-ground; fo that to work in a *fquare,* is to ride along each of thefe four lines, turning the hand at every corner, and fo paffing from one line to another.

SQUARE, in the fea language, is to fet even. Thus they fay, *fquare the yards;* that is, fet them right acrofs the fhip. See the article YARD.

SQUARTIA, in ichthyology, a fpecies of fifh found in the Eaft-Indies, the fkin of which makes the fhagreen. *Hofm.* Lex. in voc. See SHAGREEN.

SQUATAROLA, in zoology, a name given by the Venetians to the grey plover, or *pluvialis cinerea.* See the article PLUVIALIS.

SQUATINATORIA, in zoology, a name by which fome authors have called the rhinobatus, a fea fifh of a fort of middle nature between the monk-fifh, or angel-fifh, and the ray. *Willughby,* Hift. Pifc. p. 79. See the article RHINOBATUS.

SQUATINA, the *monk-fifh,* called alfo in Italian the *pefce angelo,* and thence in Englifh the *angel-fifh.*

It is of a middle fhape, between the long and flat cartilagineous fifhes, being much broader than the galei, and rounder

rounder than the rays. It grows to a very large ſize, ſometimes to four, five, or ſix feet long. It is covered all over with a mucous ſubſtance, but under it the ſkin is harſh, and rough enough to ſerve for the poliſhing wood and ivory. It is of a browniſh grey on the back and ſides, and white under the belly. The head is flatted and roundiſh, and the mouth large, and opening at the extremity of the ſnout, not, as in other of the fiſhes of this claſs, under the head. It has three rows of teeth, eighteen in a row. Its eyes are large, and placed near its mouth, and ſeem as if meant for looking ſideway, rather than up or down. Its upper pair of fins very much reſemble wings, from whence it has its name of the *angel-fiſh*, and at the extremities of theſe are a number of ſharp hooked thorns. It has alſo a row of ſhort prickles on its back. See Tab. of Fiſhes, N° 7.

It is common in the Engliſh ſeas, and is not unfrequently caught in Cornwall. *Johnſon*, de Piſc. p. 23.

SQUATT, in mineralogy, a term given by the Engliſh miners to a peculiar ſort of bed of ore, leſs valuable than a load or vein, becauſe of its reaching but a little way.

Though the ore of the *ſquatts* is generally very rich and good, not inferior in quality to the beſt vein-ore, the miners are often terribly diſappointed, on finding theſe *ſquatts* inſtead of the right veins, after a long ſearch. In the tin countries, the way of ſearching for mines is by looking after the ſhoad-ſtones; that is, certain metalline ſtones which contain ſome ore, and which have originally made the upper part of the vein of ore, reaching up to the day, or the ſurface of the earth. See SHOAD.

In the time of the deluge theſe upper parts of the veins have been waſhed off, and carried down the ſides of the hills, in which the mines uſually lie, into the flat country, but they always lie in a regular and continued train, from the orifice of the mine to the fartheſt part of the train; ſo that when but one ſtone of this kind is found, the miners are certain of coming to the bed of metal, on tracing it up to its head by the train. This is a laborious and expenſive work, becauſe the ſtones never lie on the ſurface, but at the different depths of one to ten feet, or any depth between theſe. The *ſquatts* have their trains of ſhoad-ſtones as well as the regular veins, and when theſe are traced to the orifice, there is the appearance of a rich load, which the proprietor is not thoroughly undeceived in, till the diggers come to the end of it.

The *ſquatt* is a bed of ore from three to ten fathom long, and uſually is about half as broad as it is long; few are larger than this ſtandard, but many much leſs. This is always flat, and thence has its name; the round collections of ore of the ſame kind being called *bonnies*. The *ſquatt* communicates with no other load or vein, but is entire of itſelf, and its extremities terminate at once, without running, into ſeveral little ſtrings, in the manner of thoſe of the right veins. It does not lie within walls, as the loads or veins always do, though it is always depoſited in the ſhelf, or faſt ground; that is, in ſtrata that have not been moved by the flood. Phil. Tranſ. N° 69.

SQUATUS, in ichthyology, a name uſed by Pliny, and other of the old Roman authors, to expreſs the fiſh called by the old Grecian writers *rhine*, and by the moderns *ſquatina*.

It is a ſpecies of the ſqualus, and is diſtinguiſhed by Artedi under the name of the *ſqualus* with no pinna ani, and with the mouth in the top of the ſnout. See SQUATINA.

SQUILL, SCILLA, or *ſquilla*. See SCILLA, *Cycl.*

Wagner recommends the powder of *ſquills*, given with nitre, in hydropical ſwellings, and in a nephritis, and mentions ſeveral examples of cures which he performed, by giving patients from four to ten grains with a double quantity of nitre. He ſays it almoſt always operates as a diuretic, ſometimes vomits or purges. Medic. Eſſ. Edinb.

Dr. Heſs ſays, he has made cures of the aſthma with the powder of *ſquills*. The efficacy of this powder of *ſquills*, from four to twelve grains, in curing the aſthma, is atteſted by ſeveral. Med. Eſſ. ibid. from Commerc. Norimb. 1737, & 1739.

SQUILACHI, in zoology, the name by which the modern Greeks call the *jackall*, or *lupus aureus* of authors. *Bellon.* lib. 2. cap. 107. See JACKALL.

SQUILLA *aquæ dulcis*, the *freſh-water ſhrimp*. Few people are aware of the vaſt deſtruction made by this little inſect among the ſmall fry of fiſh. This inſect is commonly very plentiful in ſtanding waters, and particularly in breeding-ponds, where they always have their prey in plenty before them; and often ſuffer none, or ſcarce any of the numerous young fry, hatched from the ſpawn of carp and tench, to live to grow up. They may be obſerved following the ſhoals of the young fry, and ſeizing multitudes one after another; and at other times lurking among the weeds, to ſeize ſuch as ſtraggle by themſelves. If one of theſe inſects be put into a baſon of water with a dozen or two of theſe young fiſh, though as big as himſelf, he will very ſoon deſtroy them all. They kill numbers that they cannot eat, but leave them to rot.

SQUIRREL, *ſciurus*, in zoology. See the article SCIURUS.

There is great diverſion in the hunting this little creature, and its fleſh is very delicate and well taſted. The only ſeaſon for hunting it is in autumn, and the beginning of winter, at which time the creature is fat; and the leaves being off the trees, it may be ſeen as it leaps from bough to bough, which when purſued it does with a ſurpriſing agility.

In the ſummer they build their neſts, which the ſportſmen call *drays*, very artificially in the tops of trees, with ſticks, moſs, and ſuch other things as the woods afford; they fill this lodging, during the ſeaſon, with nuts and other fruits, which are to ſerve them in the ſevere weather, when the trees afford nothing. They ſleep in the midſt of this proviſion a great part of the winter, and that ſo found, that they will not be waked by ever ſo loud a noiſe made juſt under their drays; though at other times they fly out immediately on hearing any noiſe, even at a conſiderable diſtance.

The tail of the *ſquirrel*, which is as large as the body, though compoſed almoſt entirely of hair, ſerves the creature, in ſome ſort, inſtead of wings; for by means of it the body is kept ſuſpended in the air, without any viſible ſinking, while the creature throws itſelf from the boughs of one tree to thoſe of another of equal height. But the more general leaps the *ſquirrel* takes, are from the outermoſt branches of a high tree to another ſomewhat lower at a diſtance; it is wonderful to ſee how far it will be carried in theſe leaps; and if it miſſes the tree it aims at, and by that means falls from the top of ever ſo high a tree to the ground, the tail ſupports it ſo well, that it comes ſoftly down, and receives no harm. The hunting of the *ſquirrel* is moſt agreeably performed in woods of a young growth, the trees of which may be ſhaken by the hand; and it is neceſſary to take out ſome means of diſlodging them from the clefts of trees, in which they will take refuge, and from which they will never be removed by mere noiſe.

Many people uſually go together on this expedition, and ſometimes they carry bows and arrows for the diſlodging the prey from theſe places; ſometimes bludgeons, or ſhort and thick ſtaves, loaded at one end with lead, to prevent their lodging in the trees, when they are thrown up. The *ſquirrel* which in her fright has taken refuge in any part of a tree, and is not to be diſlodged either by hollooing or ſhaking the tree, will always quit the place as ſoon as an arrow, or bludgeon, has been well aimed at her, and will give a farther chaſe.

The *ſquirrel* is always fond of a large oak in time of danger, and runs to the neareſt ſhe can find as ſoon as ſhe ſees herſelf purſued: in ſome part of the upper boughs of this tree ſhe ſits ſecure from the men and dogs, and as it is too troubleſome to the ſportſmen to climb every tree, the only method is to ſhoot arrows, and throw bludgeons at her; ſhe is very ſeldom hurt by theſe, unleſs hit juſt upon the head, for her backbone is ſo ſtrong, that ſhe will bear very nearly as hard a blow as a dog without danger of hurt. So long as the ſtrength and ſpirits of the creature laſt, ſhe always keeps in the tops of the higheſt trees, but when ſhe grows weary ſhe comes down, and takes ſhelter in the hedges; ſhe then ſoon becomes a prey to the dogs, or is very often killed upon the ground, in attempting to gain the hedge in places where there is no continued chain of trees by which ſhe can come at it.

The common *ſquirrel*, when it would croſs a water, is often ſeen to get upon ſome light piece of wood, and ſail over by means of her tail.

Flying-SQUIRREL. The *flying-ſquirrel* is a creature famous in hiſtory for being one of thoſe few animals which ſhew, that nature has given to ſome quadrupeds a power of flying.

This however is an obſervation not ſo well verified in this creature as in the bat, which is truly a quadruped, its fore feet being only expanded into wings, and webbed, and which truly flies; whereas all that is called flying in this *ſquirrel*, is only its ſuſpending itſelf in the long leaps it makes by means of a membrane on each ſide of the body, attached to the fore legs, and reaching to the hinder ones, only growing narrower all the way.

This creature is found in ſeveral parts of America, and in many places on the confines of Ruſſia toward Tartary. It lives in hollow trees, and covers itſelf carefully up with moſs. It ſeldom ſtirs abroad in the day-time, but toward evening goes out in ſearch of food. When kept within doors it ſleeps the whole winter, but revives in ſpring. The manner in which they catch them in Ruſſia is this: they tie a net over the hole in a tree where they ſuſpect any of theſe creatures to lie hid, then they kindle a fire of ſtraw, or light buſhes about the foot of the tree, and as ſoon as this begins to ſmoak pretty much, the creatures come out of the holes, and are taken in the net. Their ſkin is extremely ſoft, and the hair is ſhort, and of a blackiſh grey. Philoſ. Tranſ. N° 427. p. 37.

STABILES, in the antient muſic, was a name given to the extreme chords of a tetrachord.

They were ſo called, becauſe they remained the ſame throughout all the genera and ſpecies of muſic [e]. One of theſe chords was the hypate, and the other the nete. They are

fometimes alfo called *ftantes*, *immobiles*, or *quiefcentes*; and by the Greeks ἑςῶτες, ἀκίνητοι, ἠρεμοῦντες [f].—[e Vid. Philof. Tranfact. N° 481. [f] *Wallis*'s Append. ad Ptolem. Harm. p. 159.]

STABLE. Nothing conduces more to the health of a horfe, than the having a good and wholfome *ftable*. The fituation of a *ftable* fhould always be in a good air, and on a firm, dry, and hard ground, that in winter the horfe may come in and go out clean. It fhould always be built fomewhat on an afcent, that the urine, and other foulneffes, may be eafily conveyed away by means of drains or finks cut for that purpofe.

As there is no animal that delights more in cleanlinefs than the horfe, or that more abominates bad fmells, care fhould be taken that there be no hog-ftie, hen-rooft, or neceffary-houfe near the place where the *ftable* is to be built; for the fwallowing of feathers, which is very apt to happen when hen-roofts are near, often proves mortal to horfes, and the fteams of a bog-houfe, or hog's dung, will breed many diftempers; and particularly, they will bring on the farcy and blindnefs in many horfes. It is much better to build the walls of a *ftable* of brick than of ftone, for the former is always dry, the other often fweats, and is very apt to be damp, and to caufe rheums and catarrhs to horfes that are fet in the *ftable* in damp weather.

The walls ought therefore to be of brick, and to be made of a moderate thicknefs, two bricks, or a brick and half at the leaft, both for the fake of fafety and warmth in winter, and to keep off the heat of the fun in the midft of fummer, which would fpoil the horfe's appetite, and fink his fpirits. The windows fhould be made on the eaft and north fides of the building, that the north air may be let in to cool the *ftables* in fummer, and the rifing fun all the year round, efpecially in winter.

The windows fhould either be fafhed, or have large cafements, for the fake of letting in air enough; and there fhould always be clofe wooden fhutters, that the light may be fhut out at pleafure; by which means the horfe will be brought to fleep in the middle of the day, as well as in the night, when it is judged proper that he fhould do fo.

Many pave the whole *ftable* with ftone, but it is much better to have that part, which the horfe is to lie upon, boarded with oak planks; for it will be not only eafier, but more warm and comfortable to the creature.

The boards muft be laid as even as poffible, for this is the way to make the creature lie moft at his eafe, and in the moft healthful pofture. The dealers in horfes generally indeed make the boards be laid higher toward the top, and flanting down: this fhews a horfe to more advantage as he lies, but it is very uncomfortable to the creature, and his hinder parts are always flipping down, and the hind legs are often made fubject to fwellings by it.

The planks fhould be laid crofswife, not lengthwife, and there are to be feveral holes bored through them to receive the urine, and carry it off underneath the floor into fome drain, or common receptacle. The ground behind fhould be raifed to a level with the planks, that the horfe may always ftand even, and the floor behind fhould be paved with fmall pebbles, and the place where the rack ftands fhould be well wainfcotted. There are to be two rings placed on each fide of the ftall, for the horfe's halter to run through, and a logger is to be fixed to the end of this, fufficient to poife it perpendicularly, but not fo heavy as to tire the horfe, or to hinder him from eating. The beft place for him to eat his corn in is a drawer, or locker, made in the wainfcot partition; this need not be large, and confequently need not take up much room, fo that it may be eafily fixed, and taken out to clean at pleafure: by this means, the common dirtinefs of a fixed manger is to be avoided.

Many people are againft having a rack in their *ftables*; they give the horfe his hay fprinkled upon his litter, and if they think he treads it too much, or too foon, they only nail up three or four boards, by way of a trough, to give it to him in. The reafon of this is, that the continual lifting up the head to feed out of the rack is an unnatural pofture for a horfe, which was intended to take his food up from the ground, and makes him, as they exprefs it, withy-cragged. In the way of fprinkling the hay on the litter, or laying it in a trough even with the ground, he not only takes it up as if from the earth in a natural way, but can eat as he lies, which is a piece of indulgence that a horfe takes great pleafure in.

When there is *ftable*-room enough, partitions are to be made for feveral horfes to ftand in; thefe fhould always allow room enough for the horfe to turn about, and lie down conveniently in, and they fhould be boarded up fo high toward the head, that the horfes placed in feparate ftalls may not be able to fmell at one another, nor moleft each other any way. One of thefe ftalls ought to be covered in, and made convenient for the groom to lie in, in cafe of a great match, or the ficknefs of a valuable horfe. Behind the horfes there fhould be a row of pegs, to hang up faddles, bridles, and other neceffary utenfils; and fome fhelves for the hanging up brufhes, &c. and the ftanding of pots of ointment and other preparations.

The *ftables* of the nobility are often incommoded by bins for oats placed in them, which take up a great deal of room with very little advantage. Dr. Plot has given us, in his hiftory of Oxfordfhire, a very convenient method, ufed by a gentleman of that county, to prevent this. It is done by making a conveniency to let the oats down from above, out of a veffel like the hopper of a mill, whence they fall into a fquare pipe of about four inches diameter, let into the wall, which comes down into a cupboard alfo let into the wall, but with its mouth fo near the bottom, that there fhall never be more than about a gallon in the cupboard at a time; which being taken out, and given to the horfes, another gallon immediately fucceeds it from above, without any trouble to the groom or any body elfe. By this means there is not an inch of room loft in the lower part of the *ftable* where the horfes ftand; and there is this great conveniency befide, that the oats are always kept fweet by it; for every gallon that is taken away puts the whole quantity above in motion, by the running down of the gallon that fupplies its place, and no muftinefs ever comes, where there is this continual airing and motion. There may eafily be contrived two of thefe, the one for the oats, the other for fplit beans; and both of thefe may be let into the range of preffes, the oats and beans being feparated above by partitions. The other requifites for a *ftable* are a dung-yard, a pump, and a conduit; and if fome pond or running river be near, it is greatly the better.

STACCATO, or STOCCATO, in the Italian mufic, intimates that every note fhould be divided and feparated from the next in a very plain and diftinct manner, and is much the fame with *fpiccato*. *Broffard*.

STACHYS, in botany, the name of a genus of plants, the characters of which are thefe. The flower confifts of one leaf, and is of the labiated kind. The upper lip is fomewhat arched, and ftands erect, the lower is divided into three fegments, of which the lower is confiderably the largeft. The piftil arifes from the cup, and is fixed in the manner of a nail to the hinder part of the flower, and furrounded with four embryos, which afterwards become fo many feeds, and ripen in the cup of the flower into a roundifh fhape. To thefe marks it may be added, that the leaves are hoary, as Diofcorides defcribes thofe of *ftachys* to be.

The fpecies of *ftachys*, enumerated by Mr. Tournefort, are thefe. 1. The great German *ftachys*. 2. The great German *ftachys* with paler flowers. 3. The broad-leaved Cretic *ftachys*. 4. The narrow-leaved Cretic *ftachys*, called *baftard ftachys*. 5. The leffer Italian *ftachys*. 6. The mullein-leaved fhrub American *ftachys*. *Tourn.* Inft. p. 186.

STÆBE, in botany, a word ufed by the Greeks as the name of feveral plants, very different one from another.

Diofcorides frequently calls the hippophaes by this name *ftæbe*; Theophraftus alfo calls his hippopheos and pheos by the fame name; and what Hippocrates fays of the fruit of the hippopheos, is by the modern Greeks interpreted the feed of the *ftæbe*. The pheos and hippopheos were thorny plants of the fhrub kind, growing on the fea-coafts of Crete and other places, and are ftill called by the inhabitants *ftæbis*. But befide thefe there was a fmall plant, called by the old Greek writers *phleos*. This was a fmall foft herb, growing in damp places, and ufed to ftuff beds with, and to other fuch purpofes. This alfo was called by the fame authors *ftæbe*. See the next article.

STÆBIS, in botany, a name given by the modern Greeks to a plant growing very plentifully in the ifland of Crete, and feeming to be the fame with the *ftæbe* of the antient Greeks, when ufed as the name of the pheos or hippopheos; for the antients ufed it alfo as the name of a low plant of the gnaphalium kind, growing in marfhy places, and ufed to ftuff beds, &c. with.

It is evident that Diofcorides calls the pheos and hippopheos, or, as he writes it, hippophaës, by the name *ftæbe*; and Neophytus tells us, that the *ftæbe* of Diofcorides was called in his time, in the vulgar Greek, *ftæbion*, and *ftæbis*.

The defcription Diofcorides gives of this plant, is, that it had fmall and flefhy flowers ftanding in clufters feveral together; and Pliny tells us, that this plant grew in fandy places near the fea-fhores, and had white prickles on the branches, and clufters of berries like the ivy. In this laft article he feems to go beyond his authority, all the Greek writers, from whom he tranflates this part of his work, fpeaking of the flowers of the *ftæbe* growing in Corymbi like the ivy, but not giving it the fruit of that plant. Honorius Bellus fays, that the flowers are mixed of a reddifh and greenifh colour; and Diofcorides fays, that the flowers of his hippopheos are mixed of a reddifh and whitifh.

The whole plant or fhrub is alfo defcribed, both by the antients and the moderns, under the names of *hippopheos* and *ftæbis*, in the fame manner: they fay it grew to about three feet high, fpreading its branches, fo as to form a round bufh, and that the prickles or thorns grew under the leaves. They were both put to the fame ufe alfo, and all the interpreters

terpreters of the old Greeks have agreed in looking upon them as synonymous terms. The fruit of the hippopheos, mentioned by Hippocrates, is rendered the seed of the *stœbis*.

STÆBIUM, in botany, a name given by the modern Greeks to the plant called *hippophaes* by Dioscorides; that author also sometimes called it *stœbe*. See the articles STÆBE and STÆBIS.

STÆCHAS, in botany, the name of a genus of plants, the characters of which are these. The flower consists of one leaf, and is of the labiated kind. The upper lip is erect and bifid, and the lower divided into three segments, the whole so disposed, that the flower has, at first sight, no appearance of a labiated one, but appears meerly a plain flower of five segments. The pistil arises from the cup, and is fixed in the manner of a nail to the hinder part of the flower: this is surrounded by four embryos, which ripen into as many seeds, contained in the cup of the flower. To these marks it is to be added, that the flowers of the *stœchases* are disposed in various series in a sort of scaly heads, from the summits of which there grow certain beautiful-coloured leaves, which Clusius calls their membranaceous ligulæ. See Tab. 1. of Botany, Class 4.

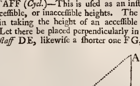
The species of *stœchas*, enumerated by Mr. Tournefort, are these. 1. The common purple *stœchas*, vulgarly called *Arabian stœchas*. 2. The naked-stalked *stœchas* with longer ligulæ. 3. The broad-leaved *stœchas* with white flowers. 4. The Portugal *stœchas* with large ligulæ, variegated with rose colour and purple. 5. The Portugal *stœchas* with green hairy leaves. *Tourn.* Inst. p. 201.

The flowers of the *stœchas* are much used in medicine, in diseases of the head and nerves, especially in such as are supposed to arise from cold causes. They also promote the evacuation by urine, and by the menses, and in some places are esteemed one of the greatest antidotes, and given in large doses against the effect of poisons, and the bites of venomous animals. Mesue, and the Arabians in general, speak of it as a purge, and particularly as good in cases where phlegm was to be evacuated; though they say it did this but slowly and weakly. At present we do not acknowledge any purging quality in it. There is a very fragrant oil drawn from the flowers and tops of this plant, in the same manner as that from lavender; but it is not much in use with us. The flowers are an ingredient in the Venice treacle, mithridate, and some other of the officinal compositions.

It is to be observed that there is another plant, called *stœchas*, in the shops; and by the writers on the materia medica, this has the epithet *citrina*, for its distinction from the *stœchas* we have been treating of, which is either called *stœchas* without any addition, or *stœchas Arabica*. The *citrine stœchas* has none of the virtues of this kind, nor is it of the same genus of plants, but of the elichrysum kind. See the article ELICHRYSUM.

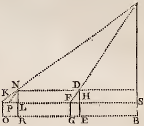
The several species of *stœchas* are propagated by sowing the seeds in March, in a bed of dry light earth; when the young plants are about three inches high, they must be removed into other beds, and placed at about six inches distance, watering and shading them till they have taken root. They must after this be kept clear from weeds, and sheltered from the severity of the winter by mats, or a light covering of peas, haulm, or other such matter; and in March, or the beginning of April, they may be removed into the places where they are to remain. The poorer the soil is, in which they are planted, the better they will stand the winter, and the more fragant will be their flowers. They may be propagated by cuttings planted in spring, but the seeds ripening very well with us, the raising them from those is the much better way. *Miller's* Gard. Dict.

STAFF (*Cycl.*)—This is used as an instrument for taking accessible, or inaccessible heights. The manner of operation, in taking the height of an accessible object, is as follows. Let there be placed perpendicularly in the ground a longer *staff* DE, likewise a shorter one FG, so as the observator may see A, the top of the height to be measured, over the ends D, F of the two *staves*; let FH and DC, parallel to the horizon, meet DE and AB in H and C, then the triangle FHD, DCA, shall be æquiangular; for the angles at C and H are right ones, likewise the angle A is equal to the angle FDH (by 29. 1. Euclid) wherefore the remaining angles DFH, and ADC, are also equal; and FH : HD :: DC : CA, *i. e.* as the distance of the staves, to the excess of the longer *staff* above the shorter; so is the distance of the longer *staff* from the object, to the excess of the height of the object above

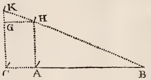


the longer *staff*. Hence CA may be found by the Rule of Three; to which if DE, the length of the longer *staff*, be added, you will have the whole height of the object. Tr. Pract. Geom. p. 19, seq.

Inaccessible heights may likewise be taken by means of two *staves*. This must be done at two stations in a right line from the object, at each of which the *staves* are to be placed in such a manner, that the summit, or top of the height, may be seen along their tops in the same right line. Thus, suppose A the summit of the object whose height is to be measured, DE, FG, the two *staves* at the first station; and RN, KO, the same *staves* at the second, so placed, that the points FDA, KNA, are in the same right line. Through the point N let there be drawn the right line NP, parallel to SFA: wherefore in the triangles KNP, KAF, the angles KNP, KAF, are equal; also the angle AKF is common to both; consequently the remaining angles KPN, KFA, are equal. And PN : FA :: KP : KF. But the triangles PNL, FAS, are similar; therefore PN : FA :: NL : SA. Thence alternately KP : NL :: KF : SA; *i. e.* as the excess of the distance of the *staves* at the second station above their distance at the first, to the difference of their lengths; so the distance of the two stations of the shorter *staff*, to the excess of the height sought above the height of the shorter *staff*. Wherefore SA may be found by the Rule of Three; to which add the height of the shorter *staff*, and the sum will give the whole inaccessible height AB. Tr. Pract. Geom. p. 22. See the articles HEIGHT and ALTITUDE, *Cycl.*



Staves may be used for measuring any distance, suppose AB, to one of whose extremities we have access. Let there be a *staff* fixed at the point A, then going back to some sensible distance, in the same right line; let another be fixed in C, so that both the points A and B may be covered or hid by the *staff* C. Likewise going off in a perpendicular, from the right line CB at the point A, let there be placed another *staff* at H; and in the right line CGK, perpendicular to the same CB at the point C, and at such a point of it K, that the points K, H and B, may be in the same right line, let there be fixed a fourth *staff*. Let there be drawn, or supposed to be drawn a right line HG parallel to CA. The triangles KHG, HAB, will be equiangular: wherefore KG : GH (= CA) :: AH : AB; *i. e.* as the excess of CK above AH is to the distance betwixt the first and second *staff*; so is the distance betwixt the first and third *staff* to the distance sought. Tr. Pract. Geom. p. 25.



STAFF, or *Catheter*, in surgery. The process of cutting for the stone, called the *high operation*, having been attended with some inconveniencies, which occasioned its being hastily left off, Mr. Cleland has attempted to remedy those inconveniencies, by means of a *catheter* of a peculiar structure, which he is of opinion, had it been known at that time when this operation was set on foot and miscarried, would have turned the advantage of the methods to the side of the high operation, and made it allowed much preferable to any other method hitherto practised, and hopes that it will be yet brought into use, and revive that method.

The *catheter* is to be made either of silver or steel, and may be of different sizes to suit different ages. It has the outward appearance of the common *catheter*, and will answer all the same uses; but in respect of this operation it differs from the common one, in that it is composed of two legs with blunt points, a long tube, a sliding bolt, and a handle, which serves to open and shut the legs. The bolt, which is fixed to the extremity of the tube, goes into two holes fixed in the plate of the handle; the one serves to keep the legs close during the time it is to be introduced into the bladder, and the other to extend them to the distance of an inch or more, during the time that the operation is performing. The structure of this *catheter* is well expressed by some figures given in N°401 of the Philosophical Transactions, and the manner of using it is this: after having taken the necessary precautions, and filled the bladder, the *catheter* is to be introduced into the bladder with its points shut; then unbolt it at the handle, and by holding the tube in one hand, and the handle that moves the legs in the other, turn or open the legs till the bolt becomes opposite to the second hole

hole upon the plate, into which it muſt be thruſt; then by preſſing gently downward the handle between the patient's legs, the two blunt points will be eaſily felt above the os pubis, in the protuberance made by the injection into the bladder. The advantages propoſed by uſing this *catheter* are theſe: firſt, it is a director to the operator, ſhewing the place in which the puncture is to be made into the bladder; it alſo ſerves as a ſupport to the bladder when the water is run out, and keeps it from ſubſiding during the time of the operation, or till the ſtone is extracted. It ſerves alſo to reſiſt the preſſure of the abdominal muſcles and the peritonæum, and hinders the inteſtines from being forced down upon the knife, keeping the orifice ſufficiently open, till the ſtone or ſtones are taken out. And finally, it may always be diſcovered, by the help of this inſtrument, whether the bladder be become ſcirrhous.

The method of performing the operation with this *catheter* is thus: after the *catheter* is introduced, and fixed with its legs open, the two points are to be felt for above the os pubis; when theſe are found, the finger and thumb are to be placed gently upon them, and the handle is to be held by an aſſiſtant, to keep it firmly in that poſition; then with a knife in the other hand a puncture is to be made immediately into the bladder, directly in the middle between the two points; but for the more ſecurity, it may be made ſomewhat lower, nearer the os pubis: when the knife is thus introduced, a large inciſion is to be made downward, inclining under the arch of the pubis, in proportion to the bigneſs of the ſtone, taking care not to wound the cartilage that joins the bones together when the knife is withdrawn. The bladder being thus ſupported, the ſtone may be taken out either with the fingers, or with a pair of tenets, there being little danger of breaking it in this method. When the operation is finiſhed, the handle of the *catheter* is to be raiſed; it is to be unbolted and ſhut cloſe, then fixed in this poſition and drawn out, and the patient dreſſed in the uſual way. Philoſ. Tranſ. Nº 401. p. 786.

Flag-STAFF, in a ſhip, the long *ſtaff*, or piece of wood, whereto the flag is made faſt, and along which it is hoiſed up.

Station-STAFF, in ſurveying, an inſtrument conſiſting of two rulers that ſlide to ten feet, divided into feet and inches, with a moveable vane or ſight, two of which are uſed with a level; and on the edges there are the links of Gunter's chain divided. Its chief uſe is for the eaſy taking off-ſets.

STAG, *cervus*, in zoology. See CERVUS.

STAG-*evil*, in the manege. See the article HART.

STAG-*worms*, in natural hiſtory, a name given to a ſpecies of worms produced of the eggs of a fly, and lodged in a very ſtrange place behind, and under the palate of the *ſtag*, or deer's mouth.

They are always found in great numbers together, and are contained in fleſhy bags, which are placed as the almonds of the ears in the human ſpecies. The huntſmen are well acquainted with theſe *worms*, and are of opinion that they are the cauſe of the falling off of the creature's horns; they eat their way to theſe, according to their opinion, through the proper parts of the head, and then gnawing them round at the roots, they are forced to fall like a tree that is ſawed off at the bottom. This however is a vulgar error. Mr. Reaumur has abundantly proved, that theſe *worms* never attempt ſo ſtrange a paſſage; they always remain where they are firſt found till they are in a ſtate to change into the flies, to whoſe eggs they owe their origin, and whoſe forms they are at length to aſſume. *Reaumur*'s Hiſt. Inſect. Vol. 9. p. 8.

STAGGERS (*Cycl.*)—The moſt approved remedy for this diſtemper, which ſhews itſelf in horſes in a giddineſs, and reeling about, in waterineſs of the eyes, and a variety of odd motions of the head, is the following method. The creature is firſt to be blooded largely, then a glyſter is to be given him, compoſed of two quarts of emetic wine, and four ounces of the unguentum populneum. When he has repoſed an hour or two after voiding this glyſter, let another be given him, made of two ounces of the, ſcoriæ of the liver of antimony finely powdered, boiled a little while in five pints of beer, and with the addition of four ounces of the ſame ointment, or of ointment of roſes. This laſt glyſter is to be frequently repeated, and his legs are to be all the while rubbed ſtrongly with whiſps of hay, wetted in warm water, to make a revulſion. His food ſhould be bran and white bread, and he ſhould be walked from time to time in ſome temperate place. If theſe methods do not ſucceed, let an ounce of Venice treacle be diſſolved in a quart of ſome cordial waters, and given him; and after this let the following glyſter be given warm: take Venice treacle and ſal polycreſtum, of each two ounces; diſſolve them in two quarts of a decoction of mallows and camomile flowers; add a quarter of a pint of oil of rue. This repeated two or three times after bleeding, and the other methods, will often cure the worſt ſtages of this diſeaſe.

Mr. Boyle mentions a cure of this diſeaſe in horſes, by rubbing their gums with the coach whip till they bleed. Works Abr. Vol. 1. p. 88.

STAGONIAS, a word uſed by the old authors to expreſs that ſort of male frankincence which is in round drops, and very clear and fine.

STAGONIUS, a name ſometimes given to ſtorax. See the article STORAX.

STAINING, or COLOURING *of porcelain*. The Chineſe, for a great many ages, uſed only white porcelain. The firſt *colour* they employed was blue, and after that they came into the uſe of all the reſt. Their antient blues was prepared by themſelves from a kind of a lapis lazuli; but we now ſupply them with the ſmalt ſo much cheaper, that it is no longer worth their while to make it themſelves. They uſed to prepare this only by giving a gentle calcination to the ſtone; and then beating it to powder, and grinding it to the utmoſt fineneſs in mortars of unglazed porcelain-ware, with peſtles of the ſame. The red, which the Chineſe uſe, is made of our green vitriol, or common copperas. They put about a pound of this into a crucible, and lute on this another crucible inverted: this laſt has a hole cut in the top, which they keep covered or open at pleaſure. They ſet this crucible in a furnace of bricks, ſo contrived, as to throw all the flame upon the lower veſſel, in the way of our chemiſts reverberatory furnaces. They make a large fire of charcoal all round it, and obſerve the hole at the top; for ſo long as there aſcend thick black fumes through that, the matter is not ſufficiently calcined. They watch the going off of this fume, and when there appears in the place of it a fine and thin cloud, they take away the crucible, the matter being then ſufficiently burnt. They try this, however, by taking a little out, and examining the colour; if it is not ſufficiently red, they let it remain longer in the fire. When they find that it is of a good colour, they take away the fire, and leave the veſſels to cool; this done, they find a cake of red matter at the bottom of the crucible, and a quantity of a finer powder about its ſides. They keep theſe ſeparate, the latter being the pureſt, the fineſt, and the brighteſt colour.

One pound of copperas affords about four ounces of this colour, and this is the red which they manage in different ſhades, and vary ſo much.

The Chineſe have alſo a white colour, which they uſe in their figures painted on the China: the ware itſelf is naturally white, and the varniſh, or oil of ſtone, is a great addition to its whiteneſs all over. But they have yet a way of making a much brighter and finer white than theſe, as may be ſeen in moſt of the fine China-ware where there is any white in the figures. This white is made in the following manner: they collect on the ſhores of their rivers a ſort of agate, which is of a whitiſh hue without veins, and tolerably tranſparent. It approaches very much to the nature of cryſtal, and probably cryſtal may be found to ſupply its place with us. They calcine this ſtone to a white powder, and to every ounce of this, when ground in their porcelain mortars to an impalpable fineneſs, they add two ounces of ceruſs in fine powder: this they mix with the varniſh, and lay on in the common way of other colours.

This white mixture ſerves not only for the colouring white, but it is the baſis of ſeveral other of thoſe beautiful colours which we ſee on the China-ware, and which our manufacturers have been often perplexed what to make of. Their green colour is made of copper ruſted with acid; and their fine deep violet colour is made of this green, by adding to it a due proportion of this white. It is not to be ſuppoſed that this effect is produced according to the common laws of mixing colours among our painters, for then the white and green would only make a paler green. But copper being a metal that as well gives a fine blue, as a fine green, according to the nature of the ſubſtances it is mixed with, the white in this caſe alters the very nature of the green, and converts it into that fine and deep violet blue, which we may draw from copper by means of any of the volatile alkalis; ſuch as ſpirit of ſal armoniac, ſpirit of hartſhorn, ſpirit of urine, or any the like liquor. The workmen know how to bring this blue to any degree, by putting in different proportions of the two colours. There is not any admixture of them, that will not produce a blue of ſome kind; but always the more of the green colour is uſed, the deeper the blue will be, and the leſs the paler. The yellow is made by an admixture of ſeven drachms of this white, and three drachms of copperas, or more, if they deſire the colour to be deeper.

Theſe colours are laid on upon the veſſels when they have been once baked, but they do not appear till the ſecond baking is over in their proper ſhades or tinges, and ſometimes ſcarce at all.

The black China is much eſteemed in the Eaſt, and particularly when it is ornamented with gold; this colour looking better with that ornament than any other. The black is always laid on when the porcelain is firſt dried, and is prepared by mixing three ounces of the fine deep blue with ſeven ounces of that fine varniſh, which they call *oil of ſtones*. This admixture gives a fine deep black. When the colour is thoroughly dry, the veſſels are baked, and when this is done the gold is laid on, and the whole is baked again in a particular furnace made for this purpoſe. If they would

have

have the black degenerate into blue, they need only add lefs of the blue, and a little of the cerufs and agate white before defcribed. They have two peculiar ways of applying the red, befide the common one, both which require a nice workman, and make the ware come very dear. They call the one of thefe *oils red*, and the other *blown red*. Obferv. fur les Coutumes de l'Afie. See *Blown* RED.

There are many things practifed by the Chinefe in their *colouring* and forming the feveral kinds of porcelain, which may be well brought into ufe among us, and give a new value to our own wares, even though we fhould never arrive at their art of making the thing itfelf. One kind of *colouring* eafily introduced among us, would be what they call *hoan ton hoan*. This produces veffels of great beauty and price, and is done in this manner. The matter, of which the veffels are made, for this purpofe, need not be fine; they ufually take any of the common veffels baked, without having been varnifhed, and confequently fimply white, and without luftre. When thefe are intended to be of one fimple *colour*, they need only be plunged into a liquid varnifh or oil, as the workmen there call it, *coloured* with fuch ingredients as will ftrike the moft lively tinges: but if it is to be *coloured* in compartments, as is ufually the cuftom with this fort of China, it is to be done by the pencil. The ufual way is to paint thefe in pannels, one green, another blue, and fo on, and they make a very agreeable appearance. There requires no more to this, than the laying on the *colours* tolerably thick with a large pencil; but if the pictures of animals, and plants are to be given, they are to be done with the moft permanent *colours*, and the veffel being again well baked, becomes very beautiful. Obferv. fur les Coutumes de l'Afie, p. 320.

The Chinefe, who are deceivers in every thing, find the way of cheating very much in regard to this fort of China-ware. They paint the flowers of plants, and fome parts of the birds, &c. in very bright colours, after the veffel has been baked. Vermilion is a fine *colour*, which they often add on this occafion; but they cannot ufe this before the baking, becaufe it would be deftroyed by the fire. Thefe *colours* which are laid on afterwards cannot laft, but foon rub off in the wiping, or ufing the things; the others laft for ever; for they are laid on with the greateft heat of all, the veffels being put into the fame furnaces to lay on thefe, as the other things are baked in for the firft time.

Salt petre, and powder of flints, are generally the things added to the *colours* thus laid on, to make them penetrate, and run properly. Thus for the fine deep violet colour, which makes the greateft figure of all others on this ware, they mix together equal quantities of the fine azure, the powder of flints and falt petre, all firft powdered feparately till perfectly fine; this is tempered with water, and then laid on with the pencil, and though it looks rough at firft, it comes out of the furnace of as beautiful a gloffy hue as any thing can be conceived. The yellow is made by mixing together three ounces of cerufs, and three ounces of powdered flints, and adding three, four, or more drachms of the red copperas, till the whole is of the proper degree of *colour*. The white is compofed only of powder of flints and cerufs, with a fmall admixture of the falt petre, or it will fucceed tolerably well without. Thefe are all the particulars neceffary to be obferved for the making a fort of porcelain of great beauty, in which the nature of the ware itfelf is not concerned; fo that it feems eafy to imitate it with any of our own wares.

In the baking of this, or any other kind of *coloured* China, the fecond time, there is, however, fome caution to be ufed in the placing the pieces. The Chinefe are very artful in their difpofition of the whole, arranging them in the moft compact manner, and putting the little ones within the great ones; but great care is alfo neceffary, that the veffels do not touch one another in the parts where they are painted, for the confequence of that would be the fpoiling of both veffels, as the *colours* would run together. The bottom of one veffel may generally be placed on the bottom of another, though both are painted, becaufe the rims are not painted, and they keep the painted parts from touching one another. High and narrow veffels, fuch as chocolate-cups, and the like, are very troublefome on this occafion. The method the Chinefe workmen take with them, is this: they place a range of them, fo as to cover the whole bottom of the furnace, and they cover this with a thin bed of broken China-ware, over which they place another row of the cups, and fo on to the top, where they lay on no covering: they never bake any thing elfe with thefe cups, when they are of this kind of twice-baked porcelain. Obfervat. fur les Coutumes de l'Afie, p. 321.

STAINING *of ftones*. The art of *ftaining* the gems and hard ftones, could it be brought to perfection, would be a very elegant and ufeful one; but it is loaded with fo many difficulties, that many, who have worked largely in the attempt, have given it up as impoffible to be carried to any degree of perfection. The heat, neceffary to be given to the ftones in the common way of attempting this operation, fpoils the ftone, in order to give it the colour. It is true, that fomething is to be done with folutions of filver, and the other metals, in acid menftrua without fire, and fomething may be done with a moderate heat alone, without the ufe of any thing elfe; but chance has difcovered another way, by which, without heat, it may be done in a very eafy manner. This was difcovered by Mr. Muller, who grinding fome aurum fulminans, made by diffolving gold in aqua regia, and precipitating it with falt of tartar, together with fome red glafs powdered, and a little water added, found that this mixture ftained the onyx, or chalcedony, of which the mortar was made. He was rubbing this mixture together to make an enamel colour, and leaving it three or four days in this little mortar, he found, that not only where it had been rubbed againft the bottom of the mortar, but where it had accidentally fplafhed againft the fides of it, and on the furface of the peftle, it had tinged them both very deeply to a fine red, leaving the intermediate parts of a true onyx, or chalcedony colour, wholly unaltered. The polifh of the ftone was not injured in the places where it was thus *ftained*, nor could any art get out the colour, though it was tried with alkalis, and other fharp liquors. This colour was not given to thefe parts of the ftone of the mortar in fimple blotches, but formed itfelf into regular lines, as we fee the natural colours of ftones do; but this not in the fame degree of colour, but fome of the lines were deeper, others paler.

This experiment was repeated in feveral other mortars of the fame ftone, but without fuccefs; on which the ftones, of which they were compofed, were examined with the help of glaffes, and it was found that this mortar chanced to be made of a more flaky chalcedony than any of the others, though it appeared equally folid and beautiful to the naked eye, and bore a polifh no way inferior to them. It may be worth while, on this occafion, ftrictly to examine ftones of this chalcedony kind, and on meeting with a plate of one of them of this flaky kind, to cover it with this mixture, and by that means give it a feries of lineations, which muft make it a very beautiful and valuable ftone. The polifh will not be injured by this, or if it fhould, the adding a new polifh will not at all affect the colours. In the fame manner the texture of ftones, intended for any other experiments in *ftaining*, fhould be confidered, and the choofing proper ones may make this procefs fucceed on them. Phil. Tranf. N° 179.

STAJOLUS, among the Romans, a meafure of length ufed in furveying land; it was equal to five palms and three fourths of a palm. *Pitifc.* in voc.

STAKE, the name of a fmall anvil ufed by fmiths; fometimes it ftands on a broad iron foot, on the work-bench, to be moved up and down occafionally; and fometimes it hath a ftrong iron fpike at the bottom, by which it is fixed to fome place on the work-bench. Its ufe is to fet fmall and cold work ftrait, by hammering it on the *ftake*, or to cut or punch upon with the cold chifel, or cold punch.

STAKE *of a plough*. The *ftake* is an upright piece of wood, paffing at its bottom through that link of the tow-chain which paffes through the box of the plough, and at its upper end receiving the end of what is called the *bridle-chain*, which ties it to the crow-ftaff, or if it be not long enough, a wyth, or cord, is ufed to tie it: it is alfo tied to it again, a little below the pillow of the plough, by another wyth or cord. *Tull's* Hufbandry. See the articles PLOUGH, PILLOW, CROWSTAVES, &c.

STAL-*boat*, a kind of fifhing-boat, mentioned 27 Eliz. c. 21. *Blount.*

STALACTAGNIA, in natural hiftory, the name of a genus of fpars. The word is derived from the Greek σταλακτὸς, ftillatitious, or formed by dropping, and ἁγνὸς, pure.

The bodies of this genus are formed by the dropping of water from the roofs of fubterranean caverns, and are the purer fort of what are called by authors *ftalactitæ*. They are cryftalline fparry bodies, formed into oblong conical figures, compofed of various crufts, and ufually found in form of icicles. Of this genus there are three known fpecies. 1. A hard and white one. This is a very beautiful body, and is found in many parts of England, as well as other countries. 2. A white fhattery one, found in the fame places. And 3. a yellow fhattery one, common with us in Yorkfhire, Devonfhire, and Derbyfhire; as alfo in many other parts of the world. *Hill's* Hift. of Foff. p. 363.

STALACTOCIBDELA, in natural hiftory, the name of a genus of fpars. The word is derived from the Greek σταλακτὸς, ftillatitious, or formed by the dropping of water, and κίβδηλος, impure.

The bodies of this genus are formed by the dropping of water from the roofs of fubterranean caverns, and are the coarfer kinds of what authors have called *ftalactitæ*. They are cryftallino-terrene fpars, formed into oblong bodies, and found hanging from the roofs of caverns and grottos.

Of this genus there are only two known fpecies. 1. A brownifh friable one, common in our fubterranean caverns, and even on the infides of new-built ftone arches, as thofe of the New Bridge at Weftminfter. And 2. a fnow-white friable one, found in fubterranean caverns in England and Germany,

Germany, and even on modern-built brick arches, as has of late been found on opening the vault under the terrace at Windsor. This, and the preceding instance, give us unquestionable evidence of the present, and daily formation of these bodies. *Hill's* Hist. of Foss. p. 367.

STALAGMITÆ. See the article STALAGMOSCIERIA.

STALAGMODIAUGIA, in natural history, the name of a genus of spars. The word is derived from the Greek σταλαγμὸς, a drop, and διαυγὴς, pellucid. The bodies of this genus are the purer kinds of what authors call *stalagmitæ*, or drop-stones.

They are spars found in form of small balls, each composed of numerous crusts, and considerably pellucid and crystalline. Of this genus there are three known species. 1. A white one with numerous thin crusts, and a smooth surface, found in many parts of Germany, and in England. 2. A greyish white one with thicker crusts, and a rougher surface. And 3. a yellow thin-crusted one with an echinated surface. These are both found in the subterranean caverns of England, and many other places, and the former of them is the *confetti di Tivoli* of the Italians. *Hill's* Hist. of Foss. p. 370.

STALAGMOS, a term used by authors to express a distillation of rheum from the head.

STALAGMOSCIERIA, in natural history, the name of a genus of spars. The word is derived from the Greek σταλαγμὸς, a drop, and σκιερὸς, opake, and expresses an opake spar, which has received its form from the dropping of water.

The bodies of this genus are the coarser kinds of what are called by authors *stalagmitæ*, and are small round masses, composed of numerous thin crusts, and of an opake and coarse structure.

Of this genus we have only two known species. 1. A small brownish white one with a smooth coat, found in Saxony, and some parts of England. And 2. a small brownish white one with thin crusts, and a large nucleus. This is found in small masses in Yorkshire, and is the substance of which the famous Ketton-stone of Rutland is composed. *Hill's* Hist. of Foss. p. 373.

Scotland affords a vast variety of the *stalagmitæ*. One cave, about eight miles distant from Aberdeen, on the sea-side, has its whole roof crusted over with *stalactitæ*, of a foot in length, hanging down like the fringe of a bed. The floor also is as deep covered with congeries of *stalagmitæ*. The upper coat, both of these and the *stalactites*, is of a sea-colour, but the inner parts are as white as sal prunellæ. The water which drops from these is of a very peculiar nature, for it is so acrimonious, that if it touch the skin but ever so slightly, it makes it smart. Near this cave there is another hollow rock, in which the *stalactitæ* make a very beautiful figure: they are all formed into long and thick columns, and stand perpendicularly, so that they represent the pipes of an organ; when broken, they are all found to be hollow within. The rock, and all the stone thereabouts, is of the limestone kind.

STALK, among botanists, that part of a plant which rises immediately from the root, and which usually supports the leaves, the flowers, and the fruit.

The term *stalk* is used on all occasions; but in speaking of the grasses, and gramineous plants, where the word *culm* is used in its place, to distinguish that peculiar kind of *stalk* which is general to all these plants, and is not found in any others. See the article PLANT.

The terms used in describing the *stalks* of plants, are; a *simple stalk*, one which runs up undivided from the root to the top.

Naked stalk, one that has no leaves.

Foliose stalk, one with leaves on it.

Ramose stalk, that which sends out branches.

Erect stalk, that which rises strait up.

Oblique stalk, that which is slanting.

Voluble stalk, that which twists round other things.

Flexuous stalk, that which bends.

Reclinate stalk, that which stoops towards the ground.

Procumbent stalk, that which lies on the ground.

Creeping, or *sarmentous stalk*, that which emits roots as it runs along.

If the *stalk* be rounded in shape, it is called *round*; if it make two angles, *ancipital*; if three, *trigonal*; if four, *square*; if more, *polygonal*.

If the *stalk* be lightly ridged and furrowed on the surface, it is said to be *striated*; if more deeply, *canaliculate*; if full of protuberances, *scabrous*; if lightly hairy, *villose*; if more roughly, *hispid*.

In the *branched stalk*, if the branches rise erect, it is expressed by *ascendant*; if they spread, by *diffuse*; if they are very large, it is called *branchiated*.

If the *stalk* divaricate, or, instead of sending out branches, it divide into them, it is called a *composite stalk*. If these divarications proceed by pairs, or if every branch be divided only into two others, it is called *dichotomous*; if it part into two series of branches, it is expressed by the term *distichous*; if it part into a multitude of ramifications, is called *subdivided*.

All these terms are used also in expressing the different states of the *culm*, which having no articulations, is called *equal*; when scaly, *squammose*.

STALK, or *stalking*, among the sportsmen, a term used to express the manner of making approaches to their game behind some animal, or the resemblance of some animal, or other object, which may be more familiar, or less terrible to the creature than the body of a man would be.

The best, of all methods for *stalking*, is by means of a real living horse, trained for the purpose. This horse should be chosen of the tallest and largest kind; no matter how old he is, but he must be well trained, and ready at command: And as there is much art required to the reclaiming a horse that is by nature wild, and apt to be frighted by noise and fire, as is the case when the gun is fired over him, the first attempt toward the training him must be the chaining up his head to a tree, and firing the gun several times very near him: at first he will be frighted, and kick and caper about, but after this has been practised many days together, he will by degrees become so tame, that a gun may be fired under his neck without starting, or taking any notice of it.

When he is thus taught to bear the noise of a gun, one great matter is obtained; what remains, is the teaching him to go in a proper manner, moving gently, and feeding as he goes, and to stand still and feed when the sportsman would have him: this is only to be done by much practice; and by his observing the motions and checks given him as signals on this occasion. The horse must be always naked for this sport, for the sight of a saddle and bridle on a horse give the birds an alarm, and they will rise and take wing, when they would otherwise have stood perfectly quiet: he must therefore only have a little slip tied about his lower chap, by means of which he may be guided as the sportsman sees occasion; and the person who uses him, must always take care to go just upon a level with his shoulders, and to guide his own feet by his. Some take their aim under the *stalking* horse's belly, but this exposes them too much to the sight of the birds, who often fly away before they can take aim; but the better way is to take the level before the creature's breast, where the whole body of the man remains as much concealed, as it was before the taking the aim.

The horse being properly trained, will walk slowly along in any sort of ground, as stubble-fields, moorish places, or the banks of rivers, and will always feed, or pretend to feed, as he is directed. The sportsman is to conceal himself and his gun behind the horse's fore shoulder, bending his body low by his side, and keeping the whole body of the horse always full between the fowl and himself. When by this means the sportsman is come so near to the birds, that the gun will reach them with strength to kill, he is never to attempt advancing any nearer, that they may not be disturbed. Some recommend the shooting over the horse's buttocks, and some over his neck, but the best way is under the neck, and before the breast; for by this means the body of the sportsman is covered by the shoulder, and his legs by the legs of the horse. It is proper also to take out a spaniel, but he must be one that is well trained to the sport, and that will lie still and close behind his master's heels, for if he is seen, the birds will immediately be gone. When the birds are shot, the dog will bring them to his master, and as they often fall in places where a man cannot come at them, this creature is of very necessary service.

This is the best of all methods of *stalking*, but as such a horse is difficult to train, and chargeable to keep, and is not always to be had, there are many other contrivances introduced to supply the place of it; among these the principal are the *stalking* wheelbarrow, the *stalking* bush, and the *stalking* hedge. The first of these is to be thus contrived: take a wheelbarrow, made on purpose of light fir, and set round about it boughs and bushes in such a manner, that you may sit in it, and not be discovered by the fowl, and drive it along without giving them disturbance. The sportsman is always to take a spaniel well trained to the sport along with him on this occasion, and when he knows the haunts of the birds, he is to level through the boughs that are placed about it, and send out his spaniel for the birds he kills.

The *stalking* bush is to be contrived of several bushes well platted together, with all their leaves on; it is to be fastened to a stake, which is to have an iron point at the end: the whole is to be of the height of a man, and thickset with boughs all the way, from top to bottom. When the sportsman sees his game before him, he is to advance slowly with this artificial bush between him and them; when he is come within a proper distance, he is to fix the bush into the ground, by running in the iron spike, and then to shoot through the boughs.

The *stalking* hedge is generally made about nine feet long, and a yard and half high: it is to be made of small wands, so woven together, as to give room for the placing of green boughs among them, that it may resemble a great growing hedge. This is to be carried before the sportsman, and, in the

the manner of the bush, it is to be fastened down, when near enough for the gun to kill from it.

As birds however are apt to have some apprehension of terror from seeing a tree or hedge move, these machines are to be carried on very slowly; and the resemblance of a real animal, as a horse or cow, are better for the purpose: these may be made of canvas, supported on a slight frame, and with tails of hair. For pheasants, woodcocks, and the like foolish birds, the common flat figure of a horse will do; but the water fowl are generally much more shy, and it is necessary, for the getting near them, to have the body made hollow, and stuffed with hay, or some other matter, to keep it out. The proper time to use these engines is either early in the morning, or late in the evening; for the sunshine in the middle of the day very soon discovers to the fowl the imperfection of the engine.

STALKER, in brick-making. See the article BRICK.

STALKERS, in our old writers, a kind of fishing-nets. Stat. 13 Rich. II. cap. 20. *Blount.*

STALLAGE, *stallagium*, in our old writers, the liberty, or right of pitching and erecting *stalls* in fairs or markets, or the money paid for the same. *Kenn.* Gloss. Terms of Law. *Blount, Cowel.*

STALLION, in the manege, in French *etalon*, a stone-horse kept to breed. See the articles HORSE and MARE.

STAMINA, (*Cycl.*) among botanists, the male organs of generation in flowers. They consist of two parts, a filament and anthera; though sometimes the latter stands alone. The filament is a slender body, supporting a tumid one, which is the anthera, on its head or top. The anthera is the great male organ of generation, is hollow, and contains in it a fine powder, called *farina fœcundans*. See GENERATION and FARINA.

STAMINEOUS, (*Cycl.*) in botany, a term used by authors for those flowers of plants which have no petals, or flower-leaves, but consist only of a number of *stamina* and pistils placed in a cup. This cup is sometimes mistaken for a flower, and its leaves thought to be true petals; but they remain when the *stamina* are fallen, and become the capsules containing the seed, which is the true character of a cup, not of a flower. *Tourn.* Inst. p. 501.

STAMNOS, an urn, or vessel, for holding water. Some authors have made it signify the bucket-head, as it is called, of those alembics which have no worm, but are cooled about the head by this means.

STAMPS, in metallurgy, a sort of large pestles lifted up by water-wheels, and serving to beat to powder the ores, and refuse of ores of metals. *Ray's* English Words, p. 116.

STANCH, or STAUNCH, a name given by the country people of Northamptonshire, and some other counties, to a species of fossil called *selenites*, from its supposed virtue in stopping fluxes of blood. *Hill's* Hist. of Foss. p. 129. See the article PACHODECARHOMBIS.

STANCHION (*Cycl.*)—STANCHIONS, in a ship, those pillars, which being set up pillarwise, do support and strengthen the waste trees.

STAND (*Cycl.*)—STAND, in commerce, a weight from two hundred and a half to three hundred of pitch. Merch. Dict.

STANDARD (*Cycl.*)—For the Roman *standards*, see the article SIGNA.

STANDEL, in our old writers, denotes a young store oak-tree, which in time may make timber; and twelve such young trees are to be left standing in every acre of wood, at the felling thereof. 35 Hen. VIII. cap. 17. 13 Eliz. cap. 25. *Blount.*

STANDING-*coin.* See the article COIN.

STANDING-*marriage*, in the law of Scotland, is used to express one actually subsisting, though perhaps reducible for adultery, or liable to be declared void for impotency, or constingency of blood; that is, consanguinity. *Bayne's* Crim. Law.

STANDING *part of the sheat*, in a ship, that part of it which is made fast to a ring at the ship's quarter. When they say *overhale the sheat*, they mean, *hale upon the standing part*; but when they say *hale the sheat* barely, they intend only of the running part.

STANDING *part of a tackle*, aboard a ship, is the end of the rope where the block is seized or fastened; as the other, which is haled, is called *fall.*

STANDING-*ropes*, in a ship, those ropes which do not run in any blocks, but are set taught, or let slack, as occasion serves; as the sheat-stays, back-stays, and the like.

STANNEL, in zoology, an English name of a species of hawk, more commonly known by the names of the *kestrel*, or the *windhover*; and called by Latin authors *tinnunculus* and *cenchris*. *Ray's* Ornitholog. p. 50. See the article TINNUNCULUS.

STANNUM, *tin.* See the article TIN.

STAPEDIUM, in anatomy, a name given by Albinus to the muscle of the stapes in the ear, called by others *stapidis musculus*, and *stapidanus musculus.*

STAPES (*Cycl.*)—This bone is very well denominated from its resemblance to a stirrup; it is divided by anatomists into its head, legs, and basis. The head is placed upon a short flatted neck, the top of it being sometimes flat, sometimes a little hollow. The two legs, taken together, form an arch like that of a stirrup, in the concave side of which is a groove, which runs through their whole length; one of the legs is longer, more bent, and a little broader than the other.

The basis resembles that of a stirrup, both in its oval shape, and union with the legs, except that it is not perforated, as the stirrups now are, but solid, like those of the antients. Round its circumference, next the legs, is a little border, which makes that side of the basis appear a little hollow; the other side is pretty smooth, and one half of the circumference is something more curve than the other. The subject being in an erect posture, the *stapes* is to be considered as lying on its side with the head turned downward, near the extremity of the leg of the incus; the basis inward being fixed in the fenestra ovalis, the longest leg backward, the shortest forward, and both in the same place. By this situation it is easy to know the *stapes* of each ear. *Winslow's* Anatomy, p. 49.

STAPHYLE, a word used by the old Greek writers, sometimes to express a grape; and sometimes a disorder of the uvula, which consists in an extenuation of its superior part, and a tumor of the inferior, whence it hangs down in the shape of a grape. The uvula, or gargareon, is also thus called by some writers.

STAPHYLEPARTES, the name of a chirurgical instrument, in use among the antients for elevating the uvula. It is mentioned by Paulus Ægineta.

STAPHYLINUS, in botany, a name given by some authors to the common *daucus sylvestris*, wild carrot, or bird's nest. *Dillen.* Cat. Giss. 150.

STAPHYLIS, a name given by some authors to a sort of cup or boat, made for feeding young children, and contrived with a spout in form of a grape or nipple.

STAPHYLODENDRON, the *bladder-nut*, in botany, the name of a genus of trees, the characters of which are these. The flower is of the rosaceous kind, being composed of a number of leaves disposed in a circular form. The cup is composed of one leaf, divided into many segments at the edge; and from this arises the pistil, which finally becomes a membranaceous fruit, inflated in the manner of a bladder, and containing hard seeds. See Tab. I. of Botany, Class 21. The species of *staphylodendron*, enumerated by Mr. Tournefort, are these. 1. The common *staphylodendron*, or *bladder-nut*. 2. The trifoliate Virginian *staphylodendron*, called by some the *wild pistacia*, or the *trefoil Virginian pistacia*. *Tourn.* Inst. p. 616.

STAPHYLOMA, in surgery, the name of a distemperature of the eye, which is of two kinds: in one the cornea is more than usually protuberant; and in the other the uvea breaks forth, and forms an unsightly tumor on the cornea, either from internal causes, or from some wounding instrument forced through the coat; in which last case, the sight of the eye is usually destroyed.

This is a very dangerous disorder, as it not only deforms the face, and destroys the sight of the eye, but very often it induces violent inflammations, headachs, restlesness, abscesses, and sometimes a cancer in these parts. In the cure of this disorder, the tumor and deformity are to be relieved by the application of compresses dipped in alum-water, together with a plate of lead and a bandage, or some proper instrument. If the uvea protrudes itself through a wound in the cornea, it should be returned with a probe, and the patient must be ordered to lie in a supine posture, and the wound must constantly be dressed with the white of an egg, and a mucilage of quince-seeds, till it is healed; and by this means the sight is often restored.

If this disorder is become inveterate and inflexible to all remedies, a needle, armed with a double thread, must be passed through the middle of the tumor, and the two ends of the thread are then to be tied on a knot, first on one side, and then on the other, by which means the tumor will gradually wither, and fall off along with the threads; but as this method occasions a continued pain, and from thence sometimes arise inflammations, it is better still to cut off the tumor with a scalpel, or scissors. *Heister's* Surgery, p. 423.

STAPIDACEUS *musculus*, in anatomy, a name given by Duverney, Douglass, and many others, to the muscle of the stapes of the ear, called by others *stapedis musculus*, and by Albinus *stapedium*. See the article EAR.

STAR (*Cycl.*)—Mr. Flamstead had observed different distances of the pole-*star* from the pole at different times of the year; and these observations were, through mistake, looked upon by some as a proof of the annual parallax of the fixed *stars*. On the whole, Mr. Flamstead concluded that the pole-*star* was 35″, 40″, or 45″ nearer the pole in December, than in May or July.

Dr. Hook had also communicated several observations on the apparent motions of the fixed *stars*; and as this was a matter of great importance in astronomy, several of the learned were desirous of verifying and confirming his observations. An instrument was accordingly contrived by Mr. George

George Graham, and executed with surprising exactness. With this instrument the *star* γ, in the constellation Draco, was frequently observed by Messrs. Molyneux, Bradley, and Graham, in the years 1725, 1726; and the observations were afterwards repeated by Mr. Bradley, with an instrument contrived by the same ingenious person, Mr. Graham, and so exact, that it might be depended on to half a second. The result of these observations was, that the *star* did not always appear in the same place, but that its distance from the zenith varied, and that the difference of the apparent places of Themis, the third satellite of Jupiter, amounted to 21 or 22 seconds. Similar observations were made on other *stars*, and a like apparent motion was found in them, proportional to the latitude of the *star*. This motion was by no means such as was to have been expected, as the effect of a parallax; and it was some time before any way could be found of accounting for this new phænomenon. At length Mr. Bradley resolved all its variety, in a satisfactory manner, by the motion of light and the motion of the earth compounded together. See Light.

Star, *starrum*, in our old writers. All the deeds, obligations, &c. of the Jews, were called *stars*, and writ for the most part in Hebrew alone, or in Hebrew and Latin; one of which yet remains in the Treasury of the Exchequer, written in Hebrew without points, the substance whereof is expressed in Latin just under it, like an English condition under a Latin obligation: this bears date in the reign of King John; and many *stars*, as well of grant and release, as obligatory, and by way of mortgage, are pleaded and recited at large in the Plea Rolls. Pasch. 9 Edw. I. *Blount.*

The word *star* is a contraction from the Hebrew *schetar*, a deed or contract.

Star *of the earth*, in botany, the name of a plant famous for its virtues in curing the bite of a mad-dog: but unhappily there has been a very great misunderstanding among authors about the plant properly signified by this name; some calling by it the *coronopus*, or buckshorn-plaintain, an herb common every where, and others a species of *lychnis*, or catch-fly, which is a very scarce plant. The original account of its nature and virtues seems to be this: King James sent to the Royal Society a dried specimen of a plant, which had been sent to him as the plant with which his dogs had been cured when bitten by a mad-dog, and the name, by which this was called, was *star of the earth.*

The plant was so ill dried, that it was not easily distinguished, but at length Mr. Ray found it to be the *sesamoides salamanticum magnum*. It does not seem, however, clear, that this was the plant vulgarly known by that name, but rather that it was gathered by some ignorant person; neither the name *star of the earth* at all agreeing with it, nor any account having been given before of its having such virtues. Dr. Grey, in his Compleat Farrier, greatly recommends the *star of the earth* in the cure of this bite, and the plant he means is plainly the *coronopus*, or buckshorn-plantane: and, upon the whole, it seems that this last mentioned is the plant properly called by this name, as its virtues have always been celebrated even in this case, and its leaves always are disposed on the earth in the form of the rays of a *star*. It is to be added to this, that the Countess of Suffolk's powder, so famous in many places for this terrible disease, and by which several persons have been known to be cured, is principally composed of this plant. Philos. Trans. N° 450. p. 455.

Star-*fish*. There are many species of the *star-fish*, and those extremely different one from another: they have different numbers of rays, but the most common kind has five. Their upper surface, or that to which the legs are not fastened, is covered with a firm and hard skin, which is full of little eminences of a harder matter, approaching to the nature of that of the shells of the echini marini, and the like. This skin is of different colours in the different species; most usually it is red, sometimes it is green, in some blue, and in others yellow, and of all the degrees of these colours, or the mixtures that may be produced from them. This colour does not extend to the under surface, that is covered all over with legs and with points, like the eminences of the upper side, only longer; these are all either whitish, or yellowish. In the center of the *fish* there may be seen a mouth or sucker, by means of which the creature draws its nourishment from the shell-fish, on which it feeds. There are five teeth placed round this sucker, or perhaps they may be more properly called *five bony forceps*; by means of which it seizes and holds fast the creature, while the sucker does its office, in draining out the juices; and probably it is by means of these that they open the bivalve shells, when they feed on the fish in them.

Every ray of the *star-fish* is furnished with so very large a number of legs, that they cover the whole surface: they are disposed in four ranges, each of which contains about 74; so that the whole ray contains 304, and consequently the *fish* has, upon all five of its rays, no less than 1520 legs. With all this numerous train of legs, however, the animal moves but very slowly; and indeed they are so soft and feeble, that they scarce deserve the name of legs, and, more properly speaking, they are only a sort of horns, like those of our garden-snails, but they serve the animal to walk with, and are therefore called legs. It is not only in their softness that they resemble the horns of snails, but their figure is also perfectly like them; so as that the comparison gives a sufficient description of them. They are capable of being contracted or shortened also, in the same manner with the horns of snails, and it is only in the time of the creature's moving that they are seen of their full length; at other times no part of them is seen but the extremity of each, which is formed like a sort of button, being somewhat larger than the rest of the horn. If one of the rays of this *fish* be turned the lower part upwards, and attentively viewed, the mechanism by which it extends its legs will be easily understood. If the ray be cut transversely in two, it is found composed of two bodies, divided from one another by a cartilaginous hard substance. This body seems composed of a vast number of vertebræ, and along it there run a great number of spherical, or oblong tubercles, very bright and transparent. There are four ranges of these, on each side two; they are formed of a fine thin transparent membrane, filled with a perfectly clear and pellucid fluid, like water. It is not difficult to conceive, that these little bladders serve to the lengthening and contracting of the legs of the animal; it is soon perceived that they are of the same number with the legs, and are ranged in the same order, so that each bladder corresponds to one leg: but the whole is perfectly explained, when on pressing one of these bladders the liquor is seen to flow out of it into the leg which it belongs to, and that the leg is extended and lengthened by this means; and that when this pressure is taken off, the fluid runs back again of itself from the leg to the bladder, and that on this the leg gradually shortens again: there is, therefore, nothing more necessary for the lengthening and contracting of the legs, than that the animal should have a power of pressing these bladders; that would always perform the first motion, and the mere ceasing to press them would perform the other.

When the under part of the rays is viewed, and the creature in motion, it is seen that the legs are elongated, and again contracted, merely by the ingress and egress of a fluid; and that the creature does not use all the legs of the same ray to walk with, but sometimes one part of them, and sometimes another, and this with great irregularity. They seize on any part of the rock, in the creature's moving, in an acute angle, and in consequence, when they set themselves strait upright again the body of the fish, must be so far pulled forward, as is the space of that angle from the perpendicular. They march with equal ease when thus inverted, and when in their natural position, and as well on sand as stones, and if in the dry, or if covered with water; but in all cases they move very slowly.

If a *star-fish* is taken up when full of water, it throws it out at different parts of its body by a vast number of little, and almost imperceptible apertures, in so many small streams or threads; and when it has discharged thus all that it will naturally, it may be made to throw out more by pressing or squeezing the rays, and by this means the pipe, by which it is thrown out, may be forced out of the body, and is then seen to be white, and of a triangular, not round figure. These are disposed in great numbers over the rays. Mem. Acad. Par. 1710.

The amazing property of reproducing the essential parts, when lost, is not confined to the polype, and some few others of the insect world, but is extended to the *star-fish*, and to the urticæ marinæ of various kinds, and probably to many others, in which we at present have no expectation of finding it. Mr. Reaumur, on the discovery of this property in the polype, observed these other animals, as they lay on the shores of Poictou, and other places, and often found that species of *star-fish*, which is very commonly known, and which has naturally five rays or arms, with only three or four, one or two being wanting; and on taking up and examining these mutilated ones, nature was always found reproducing the limb that was wanting; and on cutting and breaking other *star-fish* into several parts, it was but a very little while before the broken parts cicatrised, and every part remained alive; and by the appearances of things there remained no doubt, but that these living pieces will all, in time, reproduce their wanting parts.

Mr. Reaumur could not stay long enough on the spot to see this, but Mr. de Villars, on the coast of Rochelle, saw the whole process very frequently in the urticæ marinæ, which he cut to pieces on purpose for the experiment, and which always reproduced the parts he had cut off; and the common fishermen of the coasts, where Mr. Reaumur was in company with Mr. Jussieu, seeing them making their experiments on the *star-fishes*, appeared to be well acquainted with their nature, and told them that they might cut aod tear them as much as they pleased, but they would not be able to kill them: so familiarly was this piece of natural history known among these people, though unknown to those who had employed their lives in the searches after such things.

Mr.

Mr. Reaumur was very ſenſible of the advantages that water inſects, and animals, have over others, as to the healing of their wounds, but was reſolved to try the experiment on ſome land animals. The creature he firſt choſe for theſe experiments was the earth-worm; and on cutting theſe creatures aſunder, though many of the pieces dried, yet he had the pleaſure of ſeeing ſome ſucceed ſo perfectly, that the tail part, which wanted not only the head, but alſo the organs of generation of both ſexes (which in theſe animals are always both contained in the ſame individual) has been ſeen to reproduce both theſe organs and the head, and become as perfect a worm as the whole was. Philoſ. Tranſ. Nº 464. Append.

STAR-*gazer*, in ichthyology, the Engliſh name of the uranoſcopus. See the article URANOSCOPUS.

STAR-*ſhot*, the common name of a gelatinous ſubſtance often found lying on the ſurface of the earth, and called by ſome *ſtar-jelly*, and *ſtar-fallen*.

The vulgar have been always of opinion, that this was produced from that meteor which they call a *falling-ſtar*; others have imagined it a vegetable ſubſtance, and ſuppoſed it grew out of the earth: neither of theſe however appear, upon a cloſe examination, to be the caſe, but that it is really the half-digeſted food of herons, bitterns, crows, ſea-mews, and coddy-moddies, principally when they have fed upon frogs or earth-worms.

The heads of frogs have been found whole in maſſes of this matter, as have alſo parts of worms; and theſe birds, when ſhot, have been found, when dying, to diſgorge a ſubſtance of the ſame kind.

It is a gelatinous ſubſtance, reſembling a thick mucilage of gum tragacanth, and is cold to the touch. There are often yellow ſpecks, and ſmall clots, like grumous blood, in it. It ſtinks like putrid fleſh when kept, and is principally found in miſty mornings, and in wet weather in autumn, winter, and ſpring. *Moreton*'s Northampt. p. 353.

Mr. Boyle ſays, he has ſeen this jelly reſolved by digeſtion only into a permanent liquor; and that a phyſician of his acquaintance extolled it as a ſpecific, outwardly applied, to wens. Works Abr. Vol. 1. p. 310.

STAR-*ſtone*, *aſteria*, in natural hiſtory, the name of a kind of extraneous foſſil, of a very regular figure and ſtructure, and approaching very much to the nature of the entrochi, having the ſame ſubſtance and inner ſtructure, and being much of the ſame ſize, though different in form: and as thoſe foſſils have fragments of ſhelly bodies, to which they are ſometimes found affixed, and appendages like branches, or the rudiments of ſuch, growing from them, ſo theſe have both the one and the other; the firſt called *aſteropodia*, and the others the *appendiculæ*, or wires of the *aſteriæ*.

The *aſteropodia*, in ſubſtance and inner ſtructure, agree perfectly with the ſhells of the echinitæ, found in our chalk-pits, and with the *aſteriæ* and entrochi; theſe bodies being all compoſed of obliquely-arranged plates of a tabulated ſpar: they are uſually compoſed of ſeveral joints, but they are only very imperfect fragments of the body of the animal the *aſteriæ* have once been a part of; the ſeveral parts of which they are compoſed are all convex on one ſide, and concave on the other, but they are of very different ſhapes, being ſometimes roundiſh, ſometimes oblong, often quadrangular, and not unfrequently of different numbers of angles. They have frequently two, ſometimes more ridges running acroſs them, and ſometimes they have tubercles, or ſmall protuberances, ſtanding either on their upper or under ſide: they are ſometimes found ſingle, but more frequently compound, or arranged into ſmaller or larger parcels, being placed one over another in the manner of the tiles of a houſe, and ſeem truly to have been originally part of an imbricated ſhell, or cruſt of ſome yet unknown ſpecies of ſea-fiſh. They are in theſe compound maſſes even very evidently fragments, and are uſually of irregularly broken figures, though ſometimes they reſemble, in ſome degree, parts of the rays of one or other of the kinds of *ſtar*-fiſh. They are uſually found looſe from the *aſteriæ*, though lying among them; but ſometimes the *aſteriæ* are regularly fixed on them, juſt as the entrochi on the modioli, and are plainly ſeen to have originally grown out of them.

The *encrinos* of authors is one kind of *aſteropodium*, and has been affirmed by ſome perfectly to agree in figure with a ray of the magellanic *ſtar*-fiſh. This is, however, ſeldom found in ſuch a compound ſtate; it uſually is met with in ſingle joints, and then is what authors call the *aſteropodium minus*, or ſmall *aſteropodium*. *Hill*'s Hiſt. of Foſſ. p. 653.

Theſe bodies are uſually of a pale bluiſh grey, or aſh colour; ſometimes they are whitiſh, and ſometimes, though more rarely, yellowiſh, or reddiſh.

Having thus far deſcribed the *aſteropodia*, which ſeem properly the baſes of the *aſteriæ*, we ſhall be more intelligible in the account of the *aſteriæ* themſelves, which are to be treated of merely as branches of them; though, from their being much more frequent than theſe their baſes, they are much more familiarly known, and uſually more regarded. The *aſteriæ* are ſhort, and commonly ſomewhat crooked angular columns, compoſed of ſeveral joints, each reſembling the figure of a radiated *ſtar*, with a greater or ſmaller number of rays in the different ſpecies: they are uſually found of about an inch in length, and of the thickneſs of a gooſe-quill. Some of them have five angles, or rays, and others only four, and in ſome the angles are equi-diſtant, while in others they are irregularly ſo; in ſome alſo they are ſhort and blunt, while in others they are long, narrow, and pointed; and ſome have their angles ſo very ſhort and obtuſe, that at firſt ſight they might be taken for *entrocho-aſteriæ*. The ſeveral joints in the ſame ſpecimen are uſually all of the ſame thickneſs; this however is not always the caſe, but in ſome they are larger at one end, and in others at the middle, than in any other part of the body; and ſome ſpecies have one of the rays bifid, ſo as to emulate the appearance of a ſix-rayed kind.

All the *aſteriæ* are naturally ſulcated between the angles, but this in a very different degree; ſome are very little ſo, while others are cut ſo deeply, that the ſingle joints of them reſemble the rowels of a ſpur. One end of the column is frequently found finely engraved along the edges of the angles, or rays, while the other end is ſmooth, or nearly ſo; and the ſame is often the caſe alſo in the ſingle joints. Not unfrequently, alſo, one end of a column is indented, and the other has five ſtriæ, running from a hollow center to the ſulci between the rays.

They are found of various bigneſſes and colours; the longeſt ſeldom arrive, however, at two inches, and they are found of all the intermediate bigneſs from this down to the length of a barley-corn: they are not unfrequently found, alſo, compreſſed and flatted, as is common to the foſſils that have been formed in animal moulds.

They are uſually found bedded in the ſtrata of clay, though not unfrequently in thoſe of a lax ſort of quarry-ſtone, and ſometimes in a harder, but that leſs frequently. They uſually have ſea-ſhells, and other marine remains, lying about them; and ſometimes theſe ſhells adhere to the *aſteriæ*, and when ſeparated from them do no injury to the *aſteriæ*, but themſelves ſhew a mark of the figure of the body, or part of the column, when a part has been always wanting in the ſhell. Had theſe ſhells been ſtuck into the bodies of the *aſteriæ*, it would have been a proof that theſe ſhells were the bodies firſt formed, and that the matter of the *aſteriæ* had been formed, or had gathered about them afterwards; but as it is, we have by it abundant proof on the other ſide of the queſtion, and may plainly diſcover that theſe *aſteriæ* are really of marine origin; and that however they may be altered in their matter or ſtructure, ſince they were depoſited in the earth, yet that they were really exiſting in this their proper form in thoſe ſeas, when the ſhells that are found adhering to them acquired their growth.

From the columns of the *aſteriæ* there are ſometimes propagated certain ſmall branches, like thoſe of the entrochi; theſe are called by authors *appendiculæ aſteriarum*, or the wires of the *aſteriæ*.

They are compoſed of ſeveral ſhort cylindric joints, with obliquely-truncated ends, and each hollowed to the middle, where there ſtands a ſmall tubercle. Theſe branches are ſometimes two inches long, and the largeſt or thickeſt joint always adheres to the *aſteria*, all the ſucceeding ones growing ſmaller, and the branch taperer toward the end. In their natural ſituation on the *aſteria*, they ſtand in regular circles at different diſtances, one above another: there is always one wire in each of the ſulci, or channels of the body, and theſe ſtand evenly againſt one another.

Theſe wires, or *appendiculæ*, are very ſeldom, however, found in this their native ſtate, or fixed to the bodies of the *aſteriæ*; they are commonly found broken off, and lying looſe among them, and the rudiments only of them remaining on the *aſteriæ*, and very rarely even theſe. The wires themſelves are more frequently found wholly ſeparate from them, and either in fragments of different lengths, or in ſingle joints, immerſed in ſtone, or lying among the ſtrata of clay. *Hill*'s Hiſt. of Foſſ. p. 654.

The *aſteria* is alſo denominated *aſtrites*, *aſtroites*, *aſtrobolus*, and *aſteriſcus*; by Geſner *ſphragis aſteros*, *ſigillum ſtellæ*, in Engliſh the *ſtarry-ſtone*.

The *aſteriæ* may be reduced to two kinds; the firſt, thoſe whoſe whole bodies make the form of a *ſtar*; the ſecond, thoſe which in the whole are irregular, but which are adorned, as it were, with conſtellations in the parts.

Dr. Liſter, for diſtinction's ſake, only gives the name *aſteria* to the former ſort, diſtinguiſhing the latter by the appellation of *aſtroites*; the other naturaliſts generally uſe the two indiſcriminately [b]. The *aſteria*, ſpoken of by the antients, appears to be this latter kind [g].—[[b] *Plott*, Nat. Hiſt. Oxfordſh. cap. 5. ſect. 16. ſeq. [g] Mercat. Metalloth. arm. 9. cap. 10.]

Some antient writers indeed ſpeak of another more extraordinary ſpecies of *aſteria*, or *aſterites*, which the ſun's rays would ſet on fire, and which on that account came into uſe for the compoſition of philtres for kindling love. *Bail.* Dict. Crit. in voc. Eſope, n. (A).

The quality of moving in vinegar, as if animated, is ſcarce perceivable in the *aſtroites*, but is ſignal in the *aſteria*.

The former muſt be broken in ſmall pieces before it will move; but the latter will move, not only in a whole joint, but in two or three knit together. *Plott*, Nat. Hiſt. Oxfordſh. ſect. 26, ſeq.

STAR-*wort*, *aſter*, in botany, the name of a genus of plants, the characters of which are theſe. The flower is of the radiated kind. Its diſk is compoſed of floſcules, and its border of ſemifloſcules: theſe all ſtand on the embryo ſeeds, and are contained in one common ſquammoſe cup. The embryos finally ripen into ſeeds, which are winged with down, and fixed to the thalamus of the flower.

The ſpecies of *aſter*, enumerated by Mr. Tournefort, are theſe. 1. The common blue Attic *ſtar-wort*. 2. The Attic *aſter* with white flowers. 3. The round-leaved hairy Auſtrian *ſtar-wort* with large blue flowers. 4. The long-leaved mountain *ſtar-wort* with large blue flowers. 5. The purple-flowered Alpine *aſter*. 6. The blue-flowered dwarf mountain *ſtar-wort*. 7. The blue-flowered Alpine Attic *ſtar-wort*. 8. The purple tripolium-flowered *aſter*. 9. The broader-leaved *aſter* with tripolium flowers. 10. The common acrid blue-flowered *aſter*, called the *blue fleabane*. 11. The great blue Attic *ſtar-wort*. 12. The leſſer blue Attic *ſtar-wort*, called the *blue Alpine fleabane*. 13. The blue-flowered willow-leaved ſea *ſtar-wort*, called *tripolium*. 14. The leſſer *tripolium*. 15. The ſmall white-flowered *tripolium*. 16. The early Pyrenean *aſter* with large blue flowers. 17. The autumnal Pyrenean *aſter* with ſmaller blue flowers. 18. The broad-leaved American *aſter* with pale blue umbellated flowers. 19. The tall hairy New England *aſter* with very large violet-purple flowers. 20. The late-flowering hairy willow-leaved American *aſter* with blue flowers. 21. The tall-branched, wild daiſy-leaved, late-flowering *aſter*. 22. The branched late-flowering purple *aſter*. 23. The broad-leaved paniculated *aſter* with deep violet-coloured flowers. 24. The blue-flowered hyſſop-leaved branched African *aſter*. 25. The white-flowered branched hyſſop-leaved African *aſter*. 26. The annual Canada branched *aſter*, called by ſome the *branched daiſy*. 27. The African *aſter* with helichryſum leaves. 28. The hairy yellow mountain *aſter atticus* with very large flowers. 29. The ſmooth mountain *aſter* with large yellow flowers. 30. The yellow-flowered *aſter* with ſweet-ſcented roots. 31. The fleabane-leaved autumnal meadow *aſter*, commonly called the *middle fleabane*. 32. The meadow Alpine *aſter* with gold-yellow flowers. 33. The yellow-flowered woolly Dutch *aſter*. 34. The very hairy and woolly Alpine *aſter*. 35. The hairy mullein-leaved *aſter*. 36. The rock *ſtar-wort* with viſcous, hairy, and ſtrong-ſcented leaves. 37. The long-leaved mountain yellow *aſter*. 38. The yellow marſh *aſter* with long woolly leaves. 39. The ſea *aſter* with a thick cylindric, and three-pointed leaf. 40. The yellow jagged-leaved marſh *aſter*, called the *jagged-leaved marſh fleabane*. 41. The marſh *aſter* with ſmall globoſe flowers. 42. The yellow-flowered tuberous-rooted ſea *aſter*, called *ſea-fleabane*. 43. The mountain willow-leaved *aſter* with yellow flowers. 44. The yellow ſweet-ſcented *fleabane* like *aſter*. 45. The fleabane-leaved yellow Alpine *aſter*. 46. The mullein-leaved *aſter* with yellow flowers. 47. The primroſe-leaved American *aſter* with yellow flowers, and a thick large cup. 48. The American primroſe-leaved *aſter* with a ſingle purple flower. 49. The ſhrubby yellow ſtœchas-leaved American *aſter* with umbellated yellow flowers. 50. The American *aſter* with large ragwort leaves, hairy underneath. 51. The yellow-flowered ſtœchas-leaved Æthiopian *aſter*. 52. The great *aſter*, commonly called *elecampane*. *Tourn.* Inſt. p. 481.

All the ſpecies of this plant are propagated by parting their roots early in ſpring, and they will grow in almoſt any ſoil or ſituation; and the larger ſorts encreaſe ſo faſt, that if not prevented, they will in a little time over-run a large ſpace of ground. They grow beſt in the ſhade. But the lower kinds do not run ſo much at the root, but ſhould be taken up and tranſplanted every other year, which will make them produce much fairer flowers. *Miller's* Gard. Dict.

Golden STAR-*wort*. See the article ASTER *Atticus*.

STAR *of Bethlehem*. See the article ORNITHOGALUM.

STARAPHAXAT, a name uſed by ſome of the old writers for any medicine that reſtrains fluxions upon the eyes, noſe, or fauces.

STARTING, in the manege. A horſe is ſaid to be *ſtarting*, ſkittiſh, or timorous, that takes every object he ſees to be otherwiſe than it is; upon which he ſtops, flies out, and ſtarts ſuddenly to one ſide, inſomuch that the rider can't make him come near the place where the object is. This fault is more common to geldings than ſtone-horſes. Such horſes alſo as have bad eyes are moſt ſubject to it, as well as thoſe that have been kept a long time in a ſtable without airing; but theſe laſt are eaſily cured of it. When you have a ſkittiſh horſe, never beat him in his conſternation, but make him advance gently, and with ſoft means, to the ſcarecrow that alarms him, till he recovers it, and gains aſſurance.

STARVING *to death*, a kind of puniſhment uſed by the people of Arragon ſome ages ago; and it is reported by Tavernier, that the chief ladies in the kingdom of Tunquin are at this day ſtarved to death for adultery.

STASIS, a word uſed by phyſicians to expreſs a ſtagnation of the humors.

STATELY, in the manege. A horſe is ſaid to be *ſtately*, that goes with a proud, ſtrutting gate.

STATER, the name of a weight among the antients, equal to four drachms.

STATHEUSIS, a word uſed by the old writers to expreſs the torrefaction, or roaſting of ſome medicines before a ſlow fire, as is done frequently at preſent with rhubarb, &c.

STATICAL, (*Cycl.*) is ſometimes applied in a peculiar ſenſe to the experiments made as to the quantity of perſpiration, and other excretions of the human body.

We have a very particular account of ſome experiments of this kind in the Philoſophical Tranſactions, N° 470, made by Dr. John Lining of Charles-Town, in South-Carolina.

STATICAL *hygroſcope*. See the article HYGROSCOPE.

STATICE, *thrift*, in botany, the name of a genus of plants, the characters of which are theſe. The flowers are collected into a head of a ſort of globular form, which is ſurrounded by a common ſcaly cup. The head is compoſed of a number of caryophylleous flowers, compoſed of ſeveral petals, and each ariſing from its own proper tubular cup. The piſtil ariſes alſo from the ſame cup, and finally becomes an oblong fruit, covered by the cup.

The ſpecies of *ſtatice*, enumerated by Mr. Tournefort, are theſe. 1. The larger *ſtatice*, *thrift*, or *ſea July flower*. 2. The ſmaller *ſtatice*. 3. The large white-flowered Alpine *ſtatice*. 4. The ſmalleſt mountain *ſtatice*. 5. The Portugal *ſtatice* with ſcorzonera leaves. 6. The large ſhrubby Portugal ſea *ſtatice* with great flowers. 7. The great Portugal *ſtatice* with capillaceous leaves. 8. The ſmalleſt Portugal *ſtatice* with capillaceous leaves. And 9. the low ſea *ſtatice* with rigid capillaceous leaves. *Tourn.* Inſt. p. 340, ſeq.

STATICULA, among the Romans, thoſe little figures with which it was uſual to adorn their drinking-cups, called *ſcyphi*. *Pitiſc.* in voc.

STATICULI, among the Romans, a kind of dancing pantomimes. *Pitiſc.* in voc. See PANTOMIME.

STATION (*Cycl.*)—We have a method of meaſuring diſtances at one *ſtation*, in the Philoſophical Tranſactions, N° 7, by means of a teleſcope. But the practice of this method does not anſwer to the theory.

STATION, *ſtatio*, στασις, in the antient muſic, was ſometimes uſed for any fixed pitch, or degree of ſound, whether produced by intention or remiſſion. Vid. *Wallis*, Append. ad Ptolem. Harmon. p. 154.

STATION-*line*, in ſurveying. See the articles LINE and SURVEYING, *Cycl.*

STATIONARY (*Cycl.*)—STATIONARY *fevers*, a term uſed by Sydenham to expreſs a peculiar kind of fever, adapted, and owing to ſome general conſtitution of the air and ſeaſons. There are certain general conſtitutions of years, which owe their origin neither to heat, cold, dryneſs, nor moiſture, but rather depend upon a certain ſecret, and inexplicable alteration in the bowels of the earth, whence the air becomes impregnated with ſuch kinds of effluvia, as ſubject the human body to peculiar diſtempers, ſo long as that kind of conſtitution prevails, which after a certain courſe of years declines, and gives way to another. Each of theſe general conſtitutions is attended with its own proper and peculiar kind of fever, which never appears in any other; and this is thence called a *ſtationary fever*.

STATIVA, among the Romans, a ſtanding camp kept for the defence of the frontiers of the empire. Theſe camps gave riſe to a great many towns, which took their names from the legion ſtationed there. *Pitiſc.* in voc.

STATORES, among the Romans, made a part of the emperor's life-guard. *Pitiſc.* in voc.

STATUARY (*Cycl.*)—STATUARY *marble*, among our artificers, the name of the ſofter white marble uſually wrought into *ſtatues*, the ſame with the Parian marble of the antients.

STATUTE (*Cycl.*)—The king's royal aſſent to a bill by his letters patent under his great ſeal, and ſigned with his hand, and declared and notified in his abſence to the lords ſpiritual and temporal, and to the commons, aſſembled together in the high houſe, is as effectual as if the king was preſent. Stat. 33 Hen. VIII. cap. 21.

Statutes were antiently proclaimed by the ſheriff, but upon the invention of printing, this method was diſcontinued. Every body is obliged to take notice of an Act of Parliament at his peril. 4 Inſt. 26.

STATUTE-*ſeſſions*, in law, a meeting in every hundred of conſtables and houſholders, by cuſtom, for the ordering of ſervants, and the debating of differences between the maſters and the ſervants, rating of ſervants wages, &c. 1 Eliz. cap. 4. *Cowel.*

STATUTO *mercatorio*, a writ for the impriſoning him that has forfeited a *ſtatute merchant* bond, until the debt is ſatisfied: and of theſe writs there is one againſt lay-perſons, and another againſt perſons eccleſiaſtical. Reg. Orig. 146, 148. *Cowel.*

STATUTO *ſtapulæ*, a writ that lies to take the body to priſon, and ſeize upon the lands and goods of one who hath forfeited the bond called *ſtatute ſtaple*. Reg. Orig. 151. *Blount*, *Cowel.*

STATUTUM *de laborariis*, an antient writ for the apprehending ſuch labourers as refuſe to work according to the *ſtatute*. Reg. Judic. 27. *Blount*, *Cowel.*

STAVESACRE, *ſtaphiſagria*, in botany. See the article STAPHISAGRIA.

Staveſacre grows in Provence, Languedoc, and many other parts of Europe. The leaves are large and finger'd, the flower blue, and ſomewhat like that of the larkſpur. The ſeed, which is the only part of the plant uſed in medicine, is of a duſky brown, and very rough on the outſide, and of a pale yellow within, and of a bitter, diſagreeable, and very acrid taſte. The ſeed ſhould be choſen new, clean, and plump. Taken inwardly they are a violent purge and vomit, in a very ſmall doſe, and are never preſcribed; but outwardly they have always been famous for deſtroying lice in children's heads. Some take it into their mouths alſo for the tooth-ach, and others have ventured to uſe gargariſms of it to cure phlegm, and as an errhine, ſnuffing it up the noſtrils. It is alſo commended for the cleanſing old ulcers. *Lemery's* Dict. de Drog.

The chief uſe of *ſtaveſacre*, as a medicine, is the deſtroying vermin in children's heads: to this end it is powdered and mixed with *cocculus indicus*, and ſeldom fails of ſucceſs. It is a violent purgative, and therefore ſeldom uſed at preſent.

STAUROPHORI, Σταυροφοροι, in church-hiſtory, certain eccleſiaſtics, whoſe buſineſs it was to carry the croſs in proceſſions. *Hofm.* Lex. in voc.

The word is compounded of σταυρος, a croſs, and φερω, I carry.

STAUROPHYLAX, Σταυροφυλαξ, in church-hiſtory, a dignified officer in the church of Conſtantinople, to whoſe care the keeping of the croſs, found by Helena, was committed. *Hofm.* Lex. univ. in voc.

The word is derived from σταυρος, a croſs, and φυλασσω, I keep.

STAXIS, a word uſed by the antient phyſicians to expreſs a diſtillation of blood in drops from the noſe.

A *ſtaxis*, in the doctrine of criſes, is juſtly condemned as indicating a weakneſs and decay of ſtrength in nature; whereas, on the contrary, free and copious diſcharges of blood from the noſe are eſteemed good indications, and often make happy criſes.

STAY (*Cycl.*)—STAY, in the manege. To *ſtay*, or ſuſtain your horſe, is to hold the bridle firm and high. We likewiſe *ſtay* or ſuſtain a horſe with the in-leg, or in-heel, when he makes his croupe go before his ſhoulders upon volts: as alſo when we hinder him to traverſe, and ride him equally, keeping him always ſubject, ſo that his croupe can't ſlip out, and he can't loſe either his cadence, or his ground, but marks all his times equal.

STEAMS. Subterranean *ſteams* often affect the ſurface of the earth in a very remarkable manner, and influence or prevent vegetation more than any thing elſe. The ſurface of ſome ground is ſo hollow and light, and ſo ſwoln by a warm and continually working ferment, that it muſt needs ſend up a warming *ſteam*; and that it does ſo, even in the coldeſt weather, is evident from the immediate melting of the ſnow that falls on it: nay, in many places, the effect of this *ſteam* is ſo great, that it melts the ſnow before it reaches the ground, ſo that it falls on it in form of rain.

Some ſtones alſo, and ſome waters, impregnate the earth by their innate warmth, ſending up a continual ſucceſſion of warm effluvia from all parts of their ſurfaces; and other ſtones have exactly a contrary effect, rendering the places where they lie barren and cold. Streams of water, which have in their ſubterranean courſe run through beds of limeſtone, marl, or chalk, are always enriched, and warmed by the *ſteams* iſſuing from thoſe ſubſtances, and mixing with them as they paſs, and conſequently theſe waters enrich the ground wherever they run; and, on the contrary, ſome waters are uliginous, or corroſive, from the *ſteams* they have received in their channels from the veins of pyrites, or beds of metalline ores. It is even reported, that the very ſubſtances of metals and minerals are thus raiſed in *ſteams*, and that the juices of plants are found loaded with them; thus we are told, that in Italy crude quickſilver is found in the juices, and at the roots of plants; and that in Moravia, Hungary, and Peru, the ſubſtances of the metals are found in the bodies of plants, particularly lead and ſilver. The Miſcellanea Curioſa of Leipſick ſpeak of wonderful appearances of gold in the form of plants, which, if true, muſt be owing to that metal's having been raiſed in *ſteams*, and carried into the veſſels of the plants in ſuch quantity, as in fine to deſtroy the vegetable appearance, and leave the figure of the plant in metal. Phil. Tranſ. N° 110.

STEATITES, in the hiſtory of foſſils, a name given by late authors to a ſubſtance called in Engliſh *ſoap-earth*, and which, though the authors on theſe ſubjects had not taken notice of that circumſtance, was the very ſubſtance called *Cimolia purpuraſcens*, or purple earth of Cimolus, by the antients. The later ages finding the purple Cimolian earth of the old writers to be wholly different from their white kind, have given that name (though it is not eaſy to gueſs why) to the common fuller's earth, which has no tinge of purple in its whole ſubſtance.

This earth however, called by us *ſoap-earth*, and *ſteatites*, is well worth enquiring after, as a ſubſtance for imitating the fine porcelain ware of China. Dr. Woodward much recommends it on this account, and repeated trials have been made of it ſince his time, and ſome of them very lately; in all which it has afforded the fineſt earthen-ware ever made with us, and promiſes fair, with good management, for the equaling any in the world.

It is dug in many parts of Devonſhire and Cornwall, and the neighbouring counties; the cliff of the Lizard point is almoſt wholly compoſed of it, and the adjacent little iſlands abound with it; and from all theſe places it might be brought, at ſmall expence, in any quantities. It is known from all other earths by theſe characters. It is compoſed of extremely fine particles, and is of a firm, equal, and regular texture, and great weight. It is very firm and hard as it lies in the earth, but when it has been ſome time expoſed to the air, it becomes almoſt of a ſtony hardneſs. It is of a perfectly fine, ſmooth, and gloſſy ſurface, ſofter to the touch than any other ſpecies of earth, and does not at all adhere to the tongue, or ſtain the fingers in handling; but drawn along a rough ſurface, as a piece of cloth, or the like, it marks it with a fine and even white line. In colour it is a clear white, veined and variegated very beautifully with purple of different degrees of deepneſs; and is of ſo fine a ſtructure of parts, that when cut into thin pieces it is in ſome degree tranſparent. It makes no efferveſcence with acids, and burns to a pure white, even in its purple parts. *Hill's* Hiſt. of Foſſ. p. 22. See TERRA *Cimolia*.

STEATOCELE, a term uſed by the antients to expreſs a ſort of rupture, occaſioned by a large quantity of fat or ſuety matter lodged in the ſcrotum.

STEEL (*Cycl.*)—The difference between *ſteel* and iron is, that *ſteel* being much the harder, will not yield to the hammer, but is brittle, inſtead of being ductile, and reſiſts the file. Malleable iron grows rigid by being ſimply extinguiſhed in cold water, but it yet retains a conſiderable degree of ductility in the cold, and may be extended in all dimenſions with the hammer.

Steel, however, if heated again, and cooled by ſlow degrees, may be filed, and extended more or leſs by the hammer. But there are many degrees in the hardening of *ſteel*; for if it has been made extremely red-hot, and is then quenched in cold water in motion, it becomes greatly harder than if it had been but moderately red-hot, and had been quenched in warm water.

Steel is alſo of a darker colour than iron, and the ſurface of it, when broken, appears to conſiſt of ſmaller granulated, or even ſtriated particles, than the iron it was made of. This appears moſt diſtinctly, when *ſteel* is welded to the ſame iron of which it was made, and the maſs made red-hot, and well incorporated by hammering. If then you harden it again, by extinguiſhing it in cold water, and poliſh it, the veins of iron are eaſily diſtinguiſhable from thoſe of the *ſteel*; the iron ones being whitiſh, and of a ſilver-like hue, the *ſteel* ones blackiſh, or like water; and when broken, the ſize of the particles is found extremely different. *Cramer's* Art of Aſſaying, p. 346.

The manner of making iron into *ſteel* had remained very long a ſecret, but many authors of late date have given the proceſs, though it does not appear the ſame in all, and in many is encumbered with circumſtances, intended only to diſguiſe it. Mr. Reaumur has taken greater pains, than almoſt any man, to come at the truth; but to be rightly informed of his reaſons, we ought to begin where he did, that is, at the origin of the iron in its pure metallic ſtate.

The ores of this metal are mixed bodies, compoſed of ſome particles truly metallic, and of others ſulphureous, ſaline, and terrene; this compound maſs is put in fuſion by the fire, and on this operation the metallic parts being heavieſt, ſubſide to the bottom of the veſſel, or furnace, and are then eaſily ſeparated from the lighter ſubſtances which float at the top. This ſeparation, however, is not ſuppoſed to be perfect, but the metal, after this its firſt fuſion, retains many heterogene particles, which prevent it from being malleable. It is after this to be refined, that is, to be melted again, and that ever ſo often performed, the metal becomes yet more and more pure and perfect, ſome heterogene matter being every time depoſited, or thrown off, and this is uſually much leſs after every fuſion.

The metal, when thus purified by melting, yet remains hard and brittle: theſe are two qualities which we do not want in iron, and this hardneſs and friability are no incompatible qualities, ſince their origin is this, that the iron in this ſtate is compoſed of a multitude of ſmall granules, every one of which is very firm and compact in its own texture, though they

they cohere but flightly one with another. The knife, or the file, cannot eafily cut any one of thefe granules, but a blow of a hammer eafily feparates large parcels of them from thofe to which they were joined : this caft iron is therefore ufed only for fuch purpofes as requires a fubftance poffeffed of thefe qualities; purpofes where hardnefs is required, and where no blows are to be met with. Thus backs of grates, iron pots, and the like, are made of it.

One of the general properties of metals is, that they are malleable ; that is, their feveral particles cohere fo well together, that they are ductile and extenfible under the hammer, and will fuffer the whole mafs to bend any way without breaking, that is, without their feparating from one another. In the words of the artizans, fuch fupplenefs and pliability is called *body* in a metal, and the caft iron, which wants this, is faid to have no body, and is what they call *no foft metal.* It is therefore no way fit for fuch works as require fafhioning by the hammer or the file, nor of fuch as are to ftand any violent blows ; but as it is eafily fufible, it ferves for caft works where there is no great delicacy in the figuring, fince it does not run fo thin as to adapt itfelf to every lineament of a fine figure, nor is qualified to be repaired by inftruments.

The ill qualities of caft iron are, in a great degree, remedied in the forged or wrought iron, taken from the fame quantity, and the fame fufion. The forging of iron is only the placing it over the fire till heated to a certain degree, and then beating it out with large hammers till it becomes foft. When it has been fufficiently forged, it becomes foft and malleable, even when cold, and when heated, is eafily wrought into any figures, which it retains always afterwards ; and it is eafily cut by the file when cold, and is not brittle on being ftruck, as is the caft iron.

While it gains thefe properties by the forging, it lofes, however, another by the fame means, which is its fufibility. It will no longer melt in the fire, but when the workmen give it the ftrongeft heat they can, it is only reduced to a fort of foft pafte, and *fweats* a little, as they exprefs it ; that is, fome few drops of truly melted iron fall from it.

It is very certain, that both the caft and the forged iron are mixtures of metalline, faline, and fulphureous particles ; and the different arrangement of thefe, in their mere fimple running together in the fufion, and their being driven intimately into, and among one another, by the hammering, makes the fufibility different in the two ftates.

If the forged iron differ greatly from the caft, there is however a third ftate into which it is reducible by art, which is yet different from both, this is what we call *fteel* ; and the quality of iron on receiving this change is not one of its leaft valuable ones, fince from this we have all our inftruments for cutting, fawing, boring, and the like purpofes, the value of which to us is almoft infinite. The German *fteel* has always been in great repute, and though feveral other nations have made it, yet the Germans have kept their method a facred myftery, to keep up their trade in it.

Steel is confiderably harder than forged iron, and fo it is neceffary that it fhould be, in order to many of the purpofes it is employed in. Shears of *fteel*, which are intended to cut iron, muft be harder than iron, otherwife their edge will turn, and they will not cut ; whereas, if the metal is too hard, then the granules will fly off, and the edge break away in fmall fragments. This is the cafe with all edged tools ; and hence it is that good *fteel* is fo nice and difficult a thing to make, fince there is required fuch a degree of hardnefs, and no more.

It is very well known, that *fteel* acquires its hardnefs from the plunging it into water ; it is to be heated to a certain degree, and then immediately plunged, while the fiery particles yet remain in it, into water perfectly cold ; it is then to be fpeedily drawn out of the water, and thus the whole operation is finifhed. It acquires its hardnefs in degrees, proportionate to its heat when plunged into the water ; and this hardnefs, or temper, remains with it only till it is heated as high again ; for after that, if it is left to cool leifurely, and not thrown into water, it is loft. All the maffes of *fteel* which are fold are thus tempered ; neverthelefs, when they are wrought into tools, their temper is loft, and is to be renewed by plunging them again into cold water, when they have been forged into the fhape of which they are to be.

Mr. Reaumur affirms, that *fteel* differs in nothing from forged iron, except that it contains more fulphurs, and more falts. Hence it follows, that caft iron fhould be *fteel*, fince it evidently differs from forged iron in the fame manner, and by the fame properties ; and in effect, caft iron is *fteel*, fuch as it is, efpecially the white fort, which is more pure, and more perfectly divefted of its earth, than the browner forts ; and this white kind may be accordingly brought to all the hardnefs of *fteel*, by repeated heating and quenching in cold water. It follows alfo, that in order to convert iron into *fteel*, we are to give it new falts, and new fulphurs. It may be afked, where is the neceffity of giving again that, which the mere caft iron poffeffes? To which the anfwer is, that *fteel* is required to be malleable in fome degree, which the mere caft iron is not ; and it is to be added to this, that it may be poffible for us to give to forged iron fuch falts and fulphurs as are more proper for the *fteel*, than thofe which the caft iron naturally poffeffes.

We have great variety of falts and fulphurs, out of which to chufe for this purpofe, and Mr. Reaumur made many trials to find which would fucceed beft ; and the refult of all was, that for fulphurs, powdered charcoal and common foot ; and for falts, fea-falt alone fucceeded beft, and that thefe were properly to be mixed with afhes, by way of an intermediate fubftance. Thefe fubftances muft alfo have their allotted dofe ; that is, there muft not only be a certain proportion of the feveral ingredients one to another, which however need not be very precife or exact, but there muft alfo be a proportional quantity of the whole employed to the quantity of iron that is to be wrought upon ; and in this alfo regard muft be had to the feveral forts of ores from which the iron was obtained, fince the iron of fome ores is much fooner convertible into *fteel* than that of others, and makes alfo a better *fteel*.

The manner of beft introducing thefe falts and fulphurs into the body of the iron, was found by this author a matter of great difficulty to determine. He foon perceived, that fire was the only agent that could convey thefe bodies into the metal ; and in contriving how this might be done moft eafily, and with leaft expence, he found out, after many trials, a new fort of furnace, which effected this purpofe with great eafe, and which was not fubject to the inconveniences of other furnaces.

As *fteel* is iron with an admixture of heterogene particles, it follows that it muft be lefs metallic, that is, lefs malleable, or more brittle ; and it is alfo neceffary that it muft be, in fome degree, malleable for the purpofes it is required for ; and it is eafy to conceive that thefe properties cannot be given it, in a proper degree, but by means of a very accurate operation ; and even when all the parts of the procefs are the fame, there is yet much depending on the iron itfelf, which can never be perfectly known but by trial. Something, however, may be judged of the iron by breaking bars of it : the feveral forts of iron, when broken, fhew fome of them only granules, others flakes, and others fibres ; fome alfo fhew all three of thefe moleculæ at once, and others two of them ; but it is eafy, in either of thefe cafes, to fee which fort is in the greateft number. The laminated and the fibrous iron are the two extremes ; the firft is very brittle, the latter very malleable. The laminated iron is ever the worft of all kinds for making into *fteel* ; and of this kind fuch pieces are worft of all, the laminæ of which are very white and fhining, and are large and irregularly difpofed, and arranged in different inclinations. Mr. Reaumur began to reckon from thefe an arrangement of all the kinds of iron, which coming, each by degrees, to have the laminæ ftill fmaller and fmaller, and at the fame time lefs glittering, and placed more evenly together, funk at laft into the irons of the granulated kind. It is eafy to conceive how many differences there muft be between thefe ; and from thefe the fibrofe ones may be deduced, owing their texture merely to the granulæ, which in thefe are difpofed into long ftrings or ftreaks. Tho' in this arrangement of the irons, the firft are, of all others, the leaft proper for making *fteel*, it does not follow that the laft are the moft fo : thefe indeed ufually make a very foft and pliant fort of *fteel*, which has what the workmen call the *greateft body* of all the kinds of *fteel*, and is therefore moft proper of all for certain purpofes, as the making watch-fprings, and the like ; but the want of hardnefs makes it very unfit for cutting tools of all kinds, from the razor to the ax. The granulated iron always makes the fineft and hardeft *fteel* ; and of thefe fuch fucceed beft, whofe granules are fmalleft.

One thing remarkable is, that all *fteel*, though made of iron of the granulated or ftriated kind, yet is, before it has been hammered, of a flaky, or a fort of laminated ftructure ; but this feems owing to the fire's having melted fome of the granules in the operation, and run feveral numbers of them together into thefe plates. The fmallnefs of thefe flakes in *fteel*, which has not been worked, are a proof of its being but of a bad kind.

A bar of iron, when converted into *fteel*, is not equally fo converted in all its parts ; the fire has always acted more ftrongly upon its furface than on its central parts, and it is therefore more perfect *fteel* there than in its inner parts ; but a perfection in the operation is not neceffary to the *fteel*'s being good and ufeful, and the whole bar is often very good *fteel*, as are alfo many bars made at the fame time, yet all perhaps fomewhat differently affected.

If the compofition, which is to convert the iron into *fteel*, be too ftrong, or if the fire be too violent, or the matter continued too long in it, in all thefe cafes the *fteel* will be over made ; that is, there will be an over proportion of faline and fulphureous parts added to the iron : thefe will therefore too far feparate the particles of the metal afunder, and the confequence will be, that the *fteel* will be too brittle to bear hammering, and will be of great lofs to the proprietor in the great quantities that will be broken, befide the lofs he

will suſtain from the abundance of ſcales which will fly off in the working. The way to meliorate ſuch *ſteel* as this, muſt be to diveſt it of part of its ſalts and its ſulphurs, but peculiarly of the laſt; and Mr. Reaumur found, that the burying the bars of ſuch *ſteel* in lime, or any other alkaline ſubſtance that would readily abſorb the ſulphurs, and placing it for a proper time in the fire, it would be in a manner decompoſed again, and come out a very good and perfect *ſteel*; and this is no trivial proof, that the account given of the manner of iron's becoming *ſteel* is the true one.

By this management *ſteel* may again be converted, or reduced to its primitive iron, and a body of any middle degree, between *ſteel* and iron, may be produced, by ſtopping this proceſs at different points of time, or continuing it till all the adventitious ſalts and ſulphurs are drawn off or abſorbed. Hardneſs and flexibility are the two great points in this operation, and what the metal gets of the one of theſe, it aſſuredly loſes of the other. The greater hardneſs is from the greater quantity of the adventitious ſalts and ſulphurs; and the greater flexibility, or, as the workmen call it, the *greater body*, is from the greater quantity of the metallic; and he who is able to calculate properly the quantities of his ſalt, charcoal, and ſoot, and to regulate exactly the degree of fire, is capable to make *ſteel* of what degree of temper or perfection he pleaſes.

Iron, impregnated with new ſalts and new ſulphurs, is not however perfectly reduced to the ſtate of what the workman expects in *ſteel*; there wants yet the quenching it while hot in cold water, to compleat the operation. The *ſteel* penetrated every way by the particles of fire, and at that inſtant plunged into water, is by that quenching ſtopt in the very ſtate in which it was, and is not ſuffered to exhale the igneous bodies, as it would otherwiſe have done. It was, while in the fire, rarified and dilated, and this quenching continues it in that ſtate, and it is found, on meaſuring, conſiderably thicker and larger than it was while unheated. It might be ſuppoſed from hence, that the particles of fire, which were lodged in the *ſteel* while red-hot, were thus detained and impriſoned in it, and ſo wrought the change, as they are known to remain in many calcined bodies, though they have not been ſo ſuddenly quenched; but if this were the caſe, the *ſteel* muſt be encreaſed in weight as well as bigneſs, as many calcined bodies are, but this is not found to be ſo in fact.

Recourſe muſt be had therefore to ſome other operation on the *ſteel*, and this appears, in reality, to be no other than the change of its texture, or internal ſtructure. If a body be naturally compoſed of a number of particles, which are in themſelves hard and compact, but between which there are certain ſpaces; if one take from thoſe hard and compact particles ſomewhat to fill up thoſe voids, it muſt appear very evidently, that though by this the proper particles are rendered leſs hard, yet the whole body muſt be made harder than it was before.

In the converting of iron into *ſteel*, Mr. Reaumur conceives that the particles of iron, being naturally very covetous of ſalts and ſulphurs, have imbibed great quantities of theſe adventitious bodies, while the ſpaces between them have been able to retain very few. This being then the firſt ſtate of the *ſteel*, when it is afterwards heated, in order to its being tempered by quenching, the fire drives theſe ſulphureous and ſaline particles, ſo abundant in the iron, out of its granules, and diſperſes them throughout the ſpaces between theſe granules; and that it is to this equal and regular diſtribution of theſe ſalts and ſulphurs, fixed in that ſtate by the immediate quenching, that the hardneſs, and other qualities of *ſteel* are owing.

To the advantage the metal gets by this means, there is however always joined a diſadvantage, which is, that its grain naturally and neceſſarily becomes coarſer by it, and the *ſteel* has the leſs body. The hardeſt *ſteel* always muſt neceſſarily have the leaſt body; but according to the rules laid down by Mr. Reaumur, one may diſpoſe the hardneſs in what degree one pleaſes, and conſequently all the other properties are in the direction of the ſame laws.

If the oppoſition of the qualities of *ſteel* be nicely conſidered, we ſhall find, that inſtead of being hurtful, they are truly what ſhould be moſt wiſhed for, and are productive of the moſt deſirable conſequences. It may appear ſomewhat ſtrange, that hardneſs and flexibility in *ſteel* ſhould be ſuch directly oppoſite and contradictory principles, and that the quenching, which makes *ſteel* more powerful to reſiſt preſſure or rubbing, ſhould at the ſame time make it more feeble in action; but this is plainly the caſe, and a piece of *ſteel* wire, which, before it is tempered by quenching, will, when hung vertically, ſuſpend a certain weight, will not ſuſtain the ſame weight when tempered, but will be broken even by a leſs; and that if the trial be made by tempering it up to one certain part, and no farther, the wire will aſſuredly break at that very part where the tempered and untempered portions meet. The encreaſe of ſize in every grain of *ſteel*, from the quenching, gives the plain ſolution of this phænomenon. The rupture of any body whatever, that is, the ſeparation of its parts, by whatever means it is done, muſt be more difficult, the more intimately thoſe parts touch, or the more points they touch in. The granules of *ſteel* are theſe touching parts, and it is very evident that theſe granules becoming larger on the quenching, muſt after this touch in fewer points, in the whole combination of the maſs; and on the other hand, as they are larger, they alſo muſt mutually touch each other in a larger ſpace. Here are two contrary principles, which conſtitute the facility and the difficulty of the rupture by different means; and it cannot be, but that the one of theſe conſtructions muſt give the greater force to reſiſt preſſure or friction, and the other to reſiſt drawing or traction.

It has been already obſerved that *ſteel* is the harder, according as it was more or leſs hot at the time when it was plunged into the water; and it muſt be added to this, that it alſo is the more ſo, the more cold the water is into which it is plunged. The degree of heat in the *ſteel* is eaſily known by its colour, and the diſtinctions in it are familiar to the workmen. Several perſons have thought there was great virtue to be communicated to the water by means of different ingredients; this Mr. Reaumur carefully tried, and the reſult was, that he found common cold water the beſt, and moſt uſeful of all liquors: it is true, that vinegar and verjuice harden the *ſteel* ſomewhat more, and aqua fortis greatly ſo, but the latter of theſe renders it too hard for ſervice; and repeated trials have evinced, that common water alone will give *ſteel* all the hardneſs it can be wiſhed to have, provided only that it be plunged into it at a time when it is ſufficiently hot.

If *ſteel*, after the tempering, be found too hard, there is a very familiar way of bringing it back to what ſtate one pleaſes, between that and iron, which is only the heating it in the fire; for it may be kept in the fire ſo long, as to be reduced wholly to iron again. It is eaſy to infer from hence, what was before obſerved, that caſt iron is *ſteel* of a peculiar kind; its properties plainly evince, that it is *ſteel* with an over proportion of all that makes it ſo, and conſequently of all its properties. It is not malleable, is very brittle, and too hard for the file, or any other tool, to cut. Theſe are the qualities of *ſteel* which is over tempered, or, as it may be called, too much *ſteel*: it owes theſe qualities to its being overcharged with thoſe ſulphurs and ſalts, which in a due proportion makes *ſteel* of iron. The method of reducing this to the ſtate of wrought iron, is the ſame with what we have before obſerved is to be uſed to untemper too high tempered *ſteel*, that is, keeping it in the fire till part of its ſalts and ſulphurs are driven off; and if the fire alone be thought too difficult, or too tedious a method, Mr. Reaumur has found that thoſe alkaline ſubſtances, which naturally abſorb ſulphurs, will aſſiſt the reducing this to the ſtate of wrought iron, as they do to the untempering of *ſteel*, and that the very ſame ſubſtances of this kind, which have been found beſt in the untempering *ſteel*, ſucceed beſt in the rendering this malleable; ſuch are lime, chalk, and the like.

Caſt iron may be taken for theſe operations in two ſtates; the one, that of ſimply melted iron in its firſt fuſion, the other that of the iron, which has been run into the mould. When a caſt piece of iron, in a certain form, is heated again with the calx of animal bones, which is one common way, this being a ſubſtance extremely diveſted of ſalts and ſulphurs, it abſorbs thoſe of the metal too greedily, and diveſts it of too great a quantity of them; ſo that when the piece comes afterwards to be filed, the fragments fly off in large ſcales, and the beauty of the caſt figure muſt be loſt: to remedy this difficulty, ſome powdered ſulphur is to be added in the heating; for this being a ſulphureous and ſaline body, checks and moderates the effects of the calx of bone.

Chalk in the ſame manner can only be employed with certain regulations; it ſucceeds very well, if the fire be not too violent, or too long continued, but if it be exceſſive in either of theſe particulars, the chalk throws into the body of the iron ſalts and ſulphurs of its own, which lay hid in its ſtructure, and which would not have been diſlodged by a ſmaller fire; but which being diſlodged, and thrown into the iron, act upon it, and render the ſucceſs of the operation quite different from what was intended, the iron becoming more hard and more brittle by it.

One great nicety in all theſe operations, is the underſtanding the ſigns by which it is known at what time caſt iron is ſufficiently ſoftened, or over tempered *ſteel* is ſufficiently reduced toward the ſtate of iron again; but this is only to be acquired by nice obſervation, and on this depends the whole certainty of the proceſſes, ſince every minute's continuance in the fire gives the operation a different turn in degree.

Mr. Reaumur, in one of his experiments in the ſoftening a piece of caſt iron of a beautiful figure, found, on taking it out, that it had loſt prodigiouſly of its weight, and coming to a nicer examination, he found that it was hollow; its outer cruſt having been ſooner converted into malleable, that is unfuſible, iron than the reſt, and the violence of the fire afterwards having melted away the inner part, which was not yet ſo changed. This accident led him to experiments, by which he found that he could, at any time, melt out

the central part of a thick ſquare bar of caſt iron, the outer part changing firſt into the condition of malleable iron, and ſerving as a crucible for the fuſion of the yet unaltered fuſible iron within. By a proper management of this diſcovery, it will be eaſy to take off the unwieldy weight of many works of caſt iron, which do not require ſo much ſtrength as that of the ſolid contained in their circumference. Mem. Acad. Scienc. Par. 1722.

Mr. Cramer obſerves, that the method of making *ſteel* out of iron, is either by fuſion, or by cementation. That by cementation may be performed in the following manner: chooſe ſome bars of pure iron, not too thick, prepare a cement of charcoal-duſt, moderately pulverized, one part, and wood-aſhes half a part; or of charcoal-duſt two parts, bones, horns, leather, or hair of animals, burnt to a blackneſs in a cloſe veſſel, and in a gentle fire, and afterwards reduced to powder, one part, wood-aſhes half a part; mix them together. Prepare a cylindrical earthen veſſel, two or three inches higher than the bars are long; put into the bottom of this veſſel the cement, prepared as before directed, ſo that being gently preſſed down, it may cover the bottom of the veſſel an inch and half deep; place then the iron bars perpendicularly, ſo that they may be every where an inch diſtant from the ſides of the veſſel, and from each other; fill the interſtices with the cement, and cover the bars with it, that the veſſel may be quite full, cover it with a tile, and ſtop the joints with a lute; put this veſſel into a furnace, and keep it moderately, but equally red-hot, for ſix or ten hours. When this is over, take the red-hot bars out, and dip them in cold water, they will then be brittle, and turned to *ſteel*. *Cramer*'s Art of Aſſaying, p. 344.

The method of making *ſteel* by fuſion is this: take of iron ore, or of unmalleable iron of the firſt fuſion, divide it into ſmall parcels, and put them into a bed made of charcoal-duſt in a ſmith's forge; let the quantity of the iron be but ſmall for the experiment; put to it, as a defenſitive menſtruum, ſome of the vitreſcent ſcoriæ of ſand, or ſtones of the ſame nature; then put upon them a quantity of charcoal, light this, and admit only a ſmall blaſt of the bellows, that the ſcoriæ and metal may both melt regularly: when this has been ſome time kept in fuſion, take it out, divide it into two parts, which make red-hot, and hammer into long bars; finally, heat them red-hot, and plunge them into cold water, and they will then be found to be *ſteel*, ſo very hard, as not to be filable, and ſo brittle, as to break aſunder when ſtruck with conſiderable force. *Cramer*'s Art of Aſſaying, p. 348.

Mr. Lemery ſhews a ſimple method of reducing *ſteel* to a very fine powder, without ruſting it: pour water on filings of *ſteel* in an earthen veſſel, till it is four inches above the filings; ſtir it well every day, ſupplying more water, as that in the veſſel ſubſides, ſo that the *ſteel* is always covered: continue this operation till the *ſteel* falls into an impalpable black powder, then dry it for uſe. Mem. de l'Acad. des Scienc. 1736.

Mr. Boyle tells us of his having opened the body of *ſteel*, by a highly rectified ſpirit of urine made *per ſe*, and poured upon new filings of the *ſteel*. This being put into a warm place, the menſtruum diſſolved a conſiderable part of the metal. See his Works Abr. Vol. I. p. 77.

Annealing, or *nealing of* STEEL, is by ſome uſed for the ſoftening it, in order to make it work eaſier; which is uſually done by giving it a blood-red heat in the fire, and then taking it out, and letting it cool of itſelf. *Mox.* Mechan. Exerc. p. 60.

Some have pretended to ſecrets in annealing, by which they could bring down iron or *ſteel* to the temper of lead: this was to be done by often heating the metal in melting lead, and letting it cool again out of the lead. But this method is found by Moxon to have no other effect than what is had from the former. *Hought.* Collect. N° 276.

Steel may indeed be made a little ſofter than in the common way, by covering it with coarſe powder of cow-horn, or hoofs; thus incloſing it in a loam, heating the whole in a wood fire till it be red-hot, and then leaving the fire to go out of itſelf, and then the *ſteel* to cool. *Mox.* loc. cit.

STEEL *glaſſes*, a name given by ſome authors to the metalline ſpheres uſed in optics. Theſe, according to Cardan, are made of three parts of braſs, one part of tin, and one of ſilver, with an eighteenth part of antimony; but moſt either totally leave out the ſilver, or add only a twenty-fourth part, to ſave the expence. There are many other methods, directed by ſeveral authors, but moſt uſe arſenic and tartar, mixed with the metals. Theſe are afterwards to be poliſhed with emery, rotten-ſtone, putty, and the like. *Merret*'s Notes on Neri, p. 342.

STEEL-*ore*, is uſed to ſignify a particular kind of lead-ore. See LEAD-*ore*.

STEEL-*waters*. See the article *Mineral* WATERS.

STEELING, in cutlery, the laying on a piece of *ſteel* upon a larger maſs of iron, to make that part which is to receive the edge harder than the reſt. The body of an ax may very well be of iron, as it never comes into uſe to cut with, and perhaps is ſtronger, and leſs liable to break, than if of *ſteel*; but it muſt have a quantity of *ſteel* at that part where the edge is to be made.

STEELYARD (*Cycl.*)—*Chineſe* STEELYARD. The people of China carry this ſtatera about them to weigh their gems, and other things of value. The beam, or *yard*, is made of wood, and is round, and a quarter of an inch over, and about a foot in length; upon this are three rules of meaſure, made of a fine ſilver-ſtudded work, as in a watch-caſe. One of theſe rules is divided into inches, and every inch into 25 parts; the other two are divided alſo into equal parts, but not into inches. They all begin from the end of the beam, whence the firſt is extended 8 inches, the ſecond 6 and $\frac{1}{2}$, the third 8 and $\frac{1}{2}$. The firſt is the European meaſure, the other two ſeem to be China meaſure, and that of ſome other nation trading with them. At the other end of the *yard* hangs a round ſcale, marked with China characters, and at three ſeveral diſtances from this end are faſtened ſo many ſlender ſtrings; the firſt diſtance makes $\frac{8}{5}$ of an inch, the ſecond is double to the firſt, and the third 4 inches and $\frac{4}{5}$. When they weigh any thing, they hold up the *yard* by ſome of theſe ſtrings, and hang a ſealed weight, of about an ounce and $\frac{1}{4}$ troy weight, upon ſome point of the rule, as the thing requires. *Grew*'s Muſeum, p. 369.

STEELYARD-*ſwing*. In the Philoſophical Tranſactions we have an account of a *ſteelyard-ſwing*, propoſed as a mechanical method for aſſiſting children labouring under deformities, owing to the contraction of the muſcles on one ſide of the body. The crooked perſon is ſuſpended with cords under his arm, and theſe are placed at equal diſtances from the center of the beam. It is ſuppoſed that the gravity of the body will affect the contracted ſide, ſo as to put the muſcles upon the ſtretch; and hence by degrees the defect may be remedied. See N° 462. ſect. 7.

STEEVE, aboard a ſhip. The ſeamen ſay that the bow-ſprit, or the beak-head of a ſhip *ſteeves*, when it ſtands too upright, and not ſtrait enough forwards.

STEEVING, in merchant ſhips, is uſed for the ſtowing of cotton, or wool, by means of ſcrews, to force it cloſe together.

STEINBIZA, in ichthyology, a name given by Hildegard, and ſome other writers, to that ſmall ſpecies of cobitis, called by others *cobitis aculeatus*, and *tænia cornuta*. It is the *cobitis* with a forked ſpine under each eye, deſcribed by Artedi. *Hildegard*, lib. 4. p. 1. See COBITIS.

STEINHUN, *ſtone-hen*, a name given by the Germans to a bird of the lagopus kind, more commonly known by the name of *otomo*, and in ſome places by that of *colmeſtre*.

It ſeems not to differ from the lagopus in any thing but colour, and that bird being known to change its colour in the ſummer months, it is probably no other *ſpecies*. *Ray*'s Ornitholog. p. 127. See the articles LAGOPUS and OTOMO.

STELE, Στηλη, in antiquity, a kind of puniſhment, being a pillar whereon a criminal was expoſed, and on which was engraven an account of his crime.

The perſons, thus expoſed to the laughter and reproaches of the people, were called *ſtelitæ*. *Potter*, Archæol. Græc. lib. 1. cap. 25. Tom. I. p. 130.

STELECHEIA, a word uſed by ſome authors to expreſs the vena portæ.

STELECHITES, in the materia medica, a name given by Dioſcorides, and ſome other of the Greek writers, to a peculiarly fine kind of ſtorax. It was the ſame with the calamite, only that this name was given to the larger, and the name *calamite* to the ſmaller or ſlenderer pieces. Pliny, Strabo, and many others, join in telling us, that the wood of the ſtorax-tree was the moſt ſubject to be eaten by worms, of that of any tree in the world.

The ſoftneſs, and ſweet taſte it had, probably rendered it liable to theſe injuries. When the worms attacked a branch, they generally eat away all the wood, and left an empty caſe of the bark, ſo that inſtead of a ſtick, there was a hollow tube like a reed: all the while that the worms were eating, the wounded veſſels poured out their balſam, and covered at length the whole ſurface with their fine pellucid yellowiſh balſam. This was doing without, while the vermin were at work within, and in conſequence, the whole ſtick, or twig, became a hollow tube, covered over with the moſt pure and fine ſtorax. This was eſteemed beyond any other ſtorax for medicinal uſes; and when in ſmall twigs, it was called *calamites*, or *calamita*, and when on larger ſticks, it was called *ſtelechites ſtorax*. When the worms attacked the body of the tree, the duſt they made by their eroſion formed a hillock or heap round the tree, or at its foot, and the extravaſated balſam running among this duſt, made a maſs that was called the *cymatius ſtorax* at that time, and was the ſame with the common ſtorax now in uſe.

STELECHITES *ſtibii facie*, in natural hiſtory, a very uncouth name given by Aldrovandus, and ſome others, to the entrochi. He gave them this name from the reſemblance of ſome of the longeſt pieces to fragments of the trunks of trees, the arms parting out from the ſides of theſe main branches, the rudiments of which are very frequent in many

of the entrochi, paffing for the remains of boughs, and the hollow in the middle, for the cavity where the pith of the tree was. The addition of *ftibii facie*, was only from the obferving that the top and bottom were radiated, or ftriated, from the central hole to the circumference, in the manner of antimony. Thefe are truly no vegetable remains, but parts of the arms of that ftrange fifh called *ftella arborefcens*.

They are all fragments, or fhort pieces, broken from larger; the longeft pieces we meet with feldom exceed two inches in length, and we find from thefe down to fingle joints, as thin as a fixpence: thefe fingle joints are diftinguifhed by authors from the compound bodies, or entrochi, by the name *trochitæ*. The largeft that we find meafure two inches in circumference, but we have from this fize to the thicknefs of the fineft pin; about a quarter of an inch in diameter is, however, the moft frequent fize. The longeft pieces confift of from twenty to thirty joints, and are very various in their thicknefs. Thefe bodies are found fometimes in clay, and fometimes in marble. The Derbyfhire marble, of late come fo much into efteem, owes all its beauty to the great quantity of them it contains; and they in fome places make up all the fubftance of the maffes of rock, only with a very flender portion of ftone to join them.

They are ufually found thrown in irregular directions, and often fhew that they have fuffered injuries by accident. In fome the joints they are compofed of are diflocated, and thruft out of their place; in others the whole fubftance is crufhed flat, as if a hollow cane were trod upon, and fqueezed to flatnefs; and in this cafe, the cracks occafioned by the injury are always manifeft. Thefe injuries muft have happened to the entrochi, while their matter was yet foft; for at this time they are fo brittle, that the force employed to diflocate, or crufh them, would only fhatter them to pieces, not take that regular effect. In fome the whole feries of joints are diflocated, and the entrochus refembles a pile of crown pieces placed on a table, and then pufhed afide, fo as not to break the pile, but force all the feveral crowns, or joints of it, to hang over one way. Some of them are found twifted like a cord, and fome have the taints evenly arranged, but ftuffed full of extraneous matter, as bricks are laid in mortar. The joints of the entrochi vary in thicknefs, from the thicknefs of a fixpence to a quarter of an inch; but this is not proportioned by their fize, for there are fome of them as fmall as pins, which yet confift of very thick joints.

The outermoft joint is in fome more deeply, and in others more flightly furrowed; and the outer circle of the points, though generally fmooth, is fometimes radiated. The rudiments of branches from the entrochi are fmall knobs, evidently broken off: they are always placed in the middle of a thick joint, between future and future, and fometimes are fingle; but fometimes there is a whole circle of them round the body of the entrochus in that joint; and fometimes, befide a regular circle of knots, there are other fmaller eminences, like warts, which ftand irregularly above and below them, and give the whole a very irregular figure. Sometimes the entrochi with thinner joints are found thus knotted, and thefe feem to have been all over covered with joints of fmaller branches; and in the living ftate of the animal, when they were perfect, muft have made a very remarkable figure. Some joints have three regular rows of knots on them, each perfectly encompaffing the entrochus; the middle row, or circle, confifts of large knots, and the upper and lower one of fmall ones. Some of the joints, inftead of having a circle of knots, rife up regularly into a circular fharp ridge between future and future; and in fome of thofe which have no rudiment of a knot on any part, the joints all rife thus regularly into fharp ridges in the middle, but that alternately, and in a very beautiful order; the one joint having a high and large ridge, and the other a fmall and low one all the way. In others there is the fame fort of difference in the joints alternately, but the one ridge is blunt, and the other fharp, and edged all the way: in thefe the joints alfo are alternately larger and fmaller, one than another. In fome the alternate edges are knotted, and in fome there is a double edge in the middle of every joint: thefe have the appearance of being compofed of a very great number of extremely thin joints, but this is not in reality the cafe. Some of thefe laft have the double edge in the center of the joint knotted at intervals, and have the appearance of ferrate edges.

Moft of the entrochi have had branches, in greater or fmaller number, iffuing from them; in all they are inferted deep into the ftem, and often, when they have been difplaced, leave deep holes in it. The ftriature of the branches runs tranfverfely to the ftriature of the main ftem: thefe branches are of various thickneffes, and fometimes very thin ones grow upon very thick ftems; but the more general rule is, that the thicker the ftem, the thicker are the branches from it. Some of the branches from the largeft ftems are found to be branched again, but this is very rare. The pieces of entrochus which we find, however large, are ufually of a cylindric figure, as thick at one end as at the other; but there are fome few found which fwell out in the middle, and grow gradually taper to each end. Thefe Agricola has defcribed, and efteems them a diftinct kind; but thefe never terminate regularly, in the manner of perfect bodies, at the ends, but are all fragments as the others are. Phil. Tranf. N° 100.

STELENCHIS, a ftrigil, or an inftrument ufed in the baths to rub off the fweat from the fkin.

STELITÆ, Στηλῖται, in antiquity, perfons who had undergone the punifhment called *ftele*. See STELE.

STELLA (*Cycl.*)—STELLA *crinita*, in natural hiftory, a name given by Linkius to a genus of *ftar-fifh*, the characters of which are thefe; that they have more than five rays, and from thefe have feveral other lateral proceffes, which are covered with a fine down or hair.

STELLA *lapis*, in the materia medica, the name of a ftone which has been very differently interpreted by different writers. Some have fuppofed it the *afteria* of Pliny, and fome the common *corolloide aftroites*; but Mefue explains it to be the *lapis lazuli*.

This ftone, and the fapphire, being both blue gems, have been very fubject to be confounded together; and the fapphire of the antients was indeed no other than a kind of lapis lazuli; but this author has always diftinguifhed between the modern fapphire and the lapis lazuli, by calling the latter *ftella lapis*, and the former *zemphyrus*. This word has been by fome written *zephyrus*, and its meaning much doubted of, but it is plainly the name of the fapphire; and this word is only formed on the Arabian name of the fame gem, which is *femphir*. See the articles ZEMPHYRUS and SEMPHIR.

STELLA *lumbricalis*, in natural hiftory, a name given by Linkius, and others, to a kind of *ftar-fifh* with an undivided body, and with five vermiform rays.

STELLA *marina*, in natural hiftory, a genus of animals, the characters of which are thefe. It is a foft animal divided into many parts, or compofed of many fegments, or lobes, running out from a central part, and refembling the radii of a circle, or the rays of a *ftar*, as it is vulgarly painted. The central part is the body, and has always a mouth in its lower fide; and the rays, commonly called *arms*, and by fome very improperly *legs*, all ftand at equal diftances from one another. The upper part of the central nucleus of this animal is called the back, and the lower the belly, but in both thefe the ftructure is very different in the feveral diftinct fpecies of the creature.

The fkeleton of the *ftar-fifh* examined, fhews the body to be made up of joints, very different in number and figure; and in fome, this articulated fubftance is made up of very fmall, and in others of very large pieces; in fome alfo it is covered with a very thick fkin, and in others with a very thin one; this however, in the firmeft ftate, never approaches to a fhelly hardnefs, and is rather callous than teftaceous, or cruftaceous, as fome have called it. The parts, of which all thefe fifh are invariably compofed, are the trunk or body, and the lobes: thefe are of no determinate figure, nor have any thing certain, but that there is a mouth, or aperture, for the taking of food, in fome part of the under plane of the trunk; and the only apparent fenfation the animal has, is that of touch or feeling. The common pofition of the mouth is in the center of the body, and the conformation of it is this: the under part of each lobe runs toward a point with the reft at the center of the body, and thefe feveral productions of the lobes make a fort of lips, the ends of each of which are armed with a number of fharp teeth, which ferve to take and convey the food into the body. From this mouth there goes a feparate canal to all, or many of the lobes, which runs through their whole length, and becomes gradually narrower, as it approaches the extremity: thefe things are conftant in all the fpecies, all their other properties differ in the different ones.

Some genera of the *ftellæ marinæ* have their body multifid, and have juft as many canals in their belly as there are lobes or arms, one conftantly and regularly running to each; while others have feveral cylindric rays or lobes, which are not perforated with any canal: hence the general number of them are divided into the whole, and the multifid kinds. In the multifid kinds the lobes, or rays, are ufually five in number, though fometimes they are more, fometimes fewer: hence authors have eftablifhed a triple diftinction of thefe creatures. 1. Thofe which have juft five rays. 2. Thofe which have more than five. And 3. thofe which have a fmaller number than that. The whole bodied ones are alfo arranged into their feveral genera in the fame manner.

The moft frequent kind of *ftar-fifh* is that which has five rays, which iffue in the manner of fo many vermiform, or worm-like proceffes: thefe therefore are called *ftellæ vermiformes*, or the worm-like *ftar-fifh*. Another kind, nearly approaching to the nature of thefe, has more than five rays, and from the fides of thefe other tranfverfe proceffes being produced, which are covered with an extremely fine kind of down, or hairynefs: thefe are called the *hairy ftar-fifh*. A third kind is called the *aftrophyta*, or plant-like *ftar-fifh*: this is compofed of a body from whence there arife a great

number of branches, which divaricating more and more, are at length encreafed, or divided into a prodigious number; and thefe being cylindric in figure, refemble very much the branches of plants.

This general diftinction being eftablifhed, the general and particular arrangements are naturally deduced from the fubordinate diftinctions: from the moft remarkable differences in each feries of *ftellæ* of every clafs are conftituted the genera; from the lefs remarkable difference among each genus, the fubordinate diftinctions, and from the minuter diftinctions among thefe, the fpecies are diftinctly feparated from one another. The accurate Linkius has hence eftablifhed a very regular method of thefe animals, calling them by names expreffive of their differences, as *oligactis*, for fuch of the firft general divifion as have lefs than five lobes, or rays, and the like. Several of the fpecies of the *ftar-fifh* are eatable, and fome of them afford a very good nourifhment. Some are prefcribed by phyficians as ingredients in plaifters.

The foffile world has been greatly enriched by the fragments and remains of the feveral kinds of *ftar-fifh* which have been converted into ftone, and have been varioufly gueffed at in that ftate, as to their origin. The afteriæ are by many affirmed to be the foffile radii of the *ftar-fifh* of the decempede, or ten-rayed kind; and others have thought it evident, that fome fpecies of them have been the remains of the common coriaceous kinds. The encrinos, or *lilium lapideum*, feems to be a part of one of the ten-rayed kinds; and the trochitæ, and entrochi, are plainly owing to the fragments of feveral of thefe kinds. *Linkius*, de Stellis Marin.

STELLA *arborefcens*. See ARBORESCENT and BASKET-*fifh*.

STELLA *occidens*, a word ufed by fome of the chemical writers to exprefs fal armoniac.

STELLA *fcolopendroides*, in natural hiftory, a name given by Linkius to a kind of *ftar-fifh* with an undivided body, and five rays, refembling the bodies of the fcolopendræ, as thofe of the more ufual kind, called *ftella lumbricalis*, do the bodies of common earth-worms. See the article STELLA *marina*, fupra.

STELLA *vermiformis*, in natural hiftory, a name given by Linkius, and other authors, to a common kind of *ftar-fifh*, which has five rays parting from the body, each fomewhat refembling the body of a large worm. See the article STELLA *marina*, fupra.

STELLARIA, in botany, a name ufed by fome authors for the *carduus ftellatus*, or *ftar*-thiftle. *Ger.* Emac. Ind. 2.

STELLARIS *lapis*, a name given by many authors to the various fpecies of *aftroites*. See the articles ASTROITES and STAR-*ftone*.

The near alliance between this name and the *afteria*, though they are the names of two foffils of an extremely different kind, has been the occafion of great errors. Authors, not converfant in foffils, have too haftily attributed to one of them the properties of the other.

Cambden tells us, that about Bevor-Caftle there are found *aftroitæ*, which he very well defcribes, as confifting of the reprefentation of feveral *ftars* fixed together by a flinty, or other extraneous matter.

STELLATE *leaf*, among botanifts. See LEAF.

STELLIO, in zoology, the name by which authors call the fwift, or fpotted lizard. The fpots which diftinguifh this kind are not, however, ftellated, as might be fuppofed from the name, but round; fome fmall, and fcattered irregularly all over the body; and others larger, and difpofed in thirteen zones, or femicircles. The fpots are much more diftinct and clear on the back than on the belly. It is common in Syria, and fome other places.

STELLIO *adufta*, an affected term ufed by fome chemical writers for cinnabar.

STELLITES, in natural hiftory, a name given by fome writers on foffils to a kind of white ftone found on Mount Libanus, and in fome other parts of Syria, containing the lineaments of the ftar-fifh compleat.

The fame ftones frequently contain the lineaments of other fifhes, principally of the bones, or fkeletons of them; and it is very certain, that the real bodies of thefe ftar-fifhes, and the bones of other fifh, after the flefh and fkin had been corrupted and worn off, have been received into this ftone while yet foft, and afterwards retained in it after its concretion: our own coal-flates fhew us innumerable inftances of leaves of plants; and the black flate of ifleb fhews us, fifhes thus preferved.

STEM (*Cycl.*)—*Falfe* STEM, in a fhip, that fixed before the right one. When a fhip's *ftem* is too flat, fo that fhe cannot keep a wind well, they ufe to put a *falfe ftem* above, which makes her rid more way, and bear a better fail.

STEMPHYLA, a word ufed by the antients to exprefs the hufks of grapes, or the remains of the preffings of wine. The fame word is alfo ufed by fome to exprefs the remaining mafs of the olives, after the oil is preffed out.

STEMPHYLITES, a name given by the antients to a fort of wine preffed hard from the hufks.

STEMPLES, in mining, crofs bars of wood in the fhafts which are funk to mines.

In many places the way is to fink a perpendicular hole, or fhaft, the fides of which they ftrengthen from top to bottom with wood-work, to prevent the earth from falling in: the tranfverfe pieces of wood, ufed to this purpofe, they call *ftemples*, and by means of thefe the miners in fome places defcend, without ufing any rope, catching hold of thefe with their hands and feet. *Ray*'s Engl. Words, p. 118.

STENO'*s duct*, a name given from its difcoverer to the fuperior falival duct. See SALIVAL, *Cycl.*

Several anatomifts, particularly Heifter and Palfyn, have difputed whether *Steno's duct* is pervious in recent fubjects, as well as in the fkeleton. Dr. Kulm affirms, he has demonftrated it to feveral to be pervious in deer, bears, wild goats, hares, calves, and in the human fubjects; and mentions the manner of tracing it. See Med. Eff. Edinb. Abridg. Vol. 2. p. 421.

STENOMARGA, in natural hiftory, a name ufed by fome authors for a light marly earth, more ufually called *agaricus mineralis*, and *lac lunæ* by the later writers, and *terra*, or *creta Seleneufiaca*, by Diofcorides and Galen. *Agricola*, de re Metal. p. 378.

STENTATO, in the Italian mufic, is ufed to fignify that the voice fhould be forced in fome part of a fong, or on fome particular found, to exprefs an extraordinary emotion.

STEP (*Cycl.*)—STEP, in a fhip, that piece of timber whereon the mafts or capftans do ftand at bottom, is called the *ftep* of the maft or capftan.

STEPHANITÆ, Στεφανῖται, in antiquity, an epithet given to games and exercifes, where the prize was only a garland. *Potter*, Archæolog. Græc. Tom. I. p. 451.

STEPHANOPHORUS, Στεφανοφόρος, in antiquity, the chief prieft of Pallas, who prefided over the reft. It was ufual for every God to have a chief prieft; that of Pallas was the *ftephanophorus*, juft mentioned, and that of Hercules was called *dadouchus*. *Potter*, Archæol. Græc. Tom. I. p. 206. See DADOUCHUS.

STEPHANOPHORUS was alfo a prieft that affifted the women in the celebration of the feftival Thefmophoria. Id. Tom. I. p. 403. See THESMOPHORIA.

STEPHENS'*s medicine for the ftone* (*Cycl.*)—Mrs. *Stephens* having fold medicines for the ftone in the bladder or kidneys, Dr. Hartley publifhed feveral cafes of their fuccefs; and fo much was faid of them, that the parliament appointed truftees to examine into the truth of what was alledged in their favour. The report of thefe truftees being favourable, fhe had five thoufand pounds fterling ordered her for publifhing the receipt. Dr. Hartley leaving out the fuperfluous part of Mrs. *Stephens*'s prefcription, reduces her receipt to a more fimple form; to wit, to two ounces and an half of foap, and feven fcruples and an half of egg-fhell powder, as the mean dofe of the medicines to be taken. Dr. Hales, after feveral trials on the different ingredients, found that the diffolving power of them lay in the lime, which Dr. Rutty confirmed; and Dr. Jurin having taken foap-lees, the ingredients of which are pot-afhes and lime, beginning with a few drops, and increafing the quantity till he took an ounce, or an ounce and an half every day, in a proper vehicle, was cured of bloody urine, pain, &c. and paffed feveral fmall ftones; after which he had no uneafinefs.

STERA, in anatomy, a word ufed by fome of the barbarous writers to exprefs the uterus. It feems to have been only a corruption of the word *hyftera*.

STERCORARIUS *pifcis*, the *dung-fifh*, the name of an Eaft-Indian fifh; fo called, from its frequenting neceffary-houfes which are over the water, and other places, where the like naftinefs is to be found. It is for this reafon fuppofed unwholefome by fome, but is really a very well-tafted fifh, and eaten by moft people where it is to be had. It is a broad and thin fifh, of about fix or feven inches long, and nearly as much in breadth. Its back is variegated with fpots of deep brown; its belly is bluifh. *Ray*'s Ichthyogr. Append. p. 2.

STERCUMEZEFF, an affected word ufed by fome of the chemical writers for litharge.

STEREO-*ftatics*, is ufed by fome for the *ftatics*, or fcience of the equilibrium of folid bodies. *Curtel.* Math. Univ. p. 79.

STERN (*Cycl.*)—STERN-*faft*, aboard a fhip, fome faftenings of ropes, &c. behind the *ftern* of a fhip, to which a cable or hawfer may be brought, or fixed, in order to hold her *ftern* to a wharf, &c.

STERN-*pofts*, in a fhip, a great timber let into the keel at the *ftern* of a fhip, fomewhat floping, into which are faftened the after-planks; and on this poft, by its pintle and gudgeons, hangs the rudder.

STERNA, in zoology, a name by which Turner, and fome others, have called a bird, known among authors by the name of the *hirundo marina*, or fea-fwallow.

It is of the fmaller kind of *lari*, or gulls, and has a forked tail. It is called the *fea-fwallow*, from its having very long wings, very fhort legs, and a forked tail, and its being almoft always on the wing. Its ufual weight is about five ounces. Its body is of a long and flender fhape, the upper part of its head is black, but it has a white line furrounding it; the belly, and under part of the wings, are white, the breaft

breaſt a little greyiſh; the rump is alſo white, but the back and wings of a blackiſh grey; its beak is ſomewhat long and ſtrait, and its legs are red. It is very common on our weſtern coaſts. It feeds on fiſh, and flies uſually in large flocks. *Ray's* Ornitholog. p. 269.

STERNOCOSTALES, commonly called the *muſculi triangulares ſterni*, are five pairs of fleſhy planes, diſpoſed more or leſs obliquely on each ſide the ſternum, on the inſides of the cartilages of the ſecond, third, fourth, fifth, and ſixth true ribs. They are inſerted by one extremity in the edges of the inſide of all the lower half of the ſternum; from thence the firſt muſcle on each ſide runs up obliquely, and is fixed in the cartilage of the ſecond rib. The ſecond runs leſs obliquely to its inſertion in the cartilage of the third rib; and the reſt are inſerted, in the ſame manner, in the cartilages of the following ribs; their obliquity decreaſing, and their length encreaſing, in proportion as they are ſituated lower down, ſo that the loweſt of all is almoſt tranſverſe. This laſt muſcle, which is fixed by one extremity in the cartilage of the ſixth true rib near the bone, ſeems to paſs the appendix enſiformis, immediately above the inſertion of the diaphragm in that appendix, and to join the muſcle on the other ſide. *Winſlow's* Anatomy, p. 233.

The *ſternocoſtalis* was called by ſome of the older anatomiſts *ſextus thoracis*; and by Riolanus, and ſome others of the later writers, *pectoralis internus*.

STERNODACTYLÆUS, in anatomy, a name given by Riolanus, and ſome others, to a muſcle of the foot, called by Albinus the *flexor brevis digitorum pedis*, and by others the *ſublimis flexor*, or *perforatus pedis*.

STERNOHYOIDÆUS, a long, thin, flat muſcle, called by ſome *ſterno-cleido-hyoidæus*.

It is broader at the lower than at the upper part, and is ſituated, together with its fellow, on the foreſide of the throat; from whence ſome have very improperly named it *muſculus bronchialis*. It is fixed by its lower extremity in the ſuperior and lateral part of the inner, or poſterior ſide of the ſternum, in the poſterior part of the ſternal extremity of the clavicula, in the tranſverſe ligament which connects thoſe two bones, and in the inner, or backſide of the cartilage of the firſt rib. All theſe other inſertions are more conſiderable than that in the ſternum, which is ſometimes ſcarce perceivable. From hence it runs up to the foreſide of the aſpera arteria, joined to its fellow by a membrane which forms a ſort of linea alba, and is inſerted laterally in the lower edge of the baſis of the os hyoides. There is ſometimes a tranſverſe tendinous line about the middle of the backſide of this muſcle. *Winſlow's* Anatomy, p. 256.

STERNOMANTIS, Στερνομάντις, in antiquity, a deſignation given to the delphian prieſteſs, more uſually called *pythia*. *Potter*, Archæol. Græc. Tom. I. p. 278. See the article Pythia, *Cycl.*

Sternomantis is alſo uſed for any one that had a propheſying demon within him. *Potter*, Archæol. Græc. Tom. I. p. 300, ſeq.

STERNOMASTOIDÆUS, a muſcle, called alſo ſimply *maſtoideus*, and *maſtoidæus anterior*, or *externus*. It is long and narrow, pretty thick, and moſtly fleſhy, and is ſituated obliquely between the back part of the ear, and the lower part of the throat. It is in a manner compoſed of two muſcles, united at the upper part through their whole breadth, and ſeparated at the lower. It has two inſertions below both of them, flat, and a little tendinous; the firſt is in the upper edge of the ſternum, near the articulation of the clavicula; and the other in the clavicula, at a ſmall diſtance from the ſternum. Theſe two portions run up obliquely, and unite together at about an inch above their lower inſertions, the triangular ſpace left between them being filled by a membrane. The ſternal portion riſes foremoſt, and covers the clavicular, both forming one body, or belly, which running in the ſame oblique direction to the apophyſis maſtoidæus, is inſerted in the upper and back part of that proceſs, over which it likewiſe ſends off a very broad aponeuroſis, which covers the ſplenius, and is inſerted in the os occipitis. The two anterior maſtoidæi repreſent a great Roman V, the angle being at the lower part of the throat, and the two crura running up behind the ears. *Winſlow's* Anatomy, p. 234.

STERNUM (*Cycl.*)—This is a long flat bone, not all of the ſame breadth, but repreſenting a kind of dagger. It is generally made up of three principal pieces; the firſt broad and ſhort, the ſecond longer and narrower, and the third a ſort of ſmall appendix, called by the Greeks *xyphoides*, from its reſemblance to the point of a broad ſword.

The firſt, or uppermoſt piece, is broad and thick at the top, but thinner and narrower below, being nearly of the figure of a triangle with the three angles cut off, or of a very irregular ſquare. The ſecond is much longer than the firſt, and is flat on both ſides, whereas the outſide of the upper is unequally convex, and the inner a little concave. This is broader alſo toward the lower, than toward the upper part, and has ſometimes ſeveral tranſverſe lines, eſpecially on its outſide, which point out the places where the pieces, of which it is made up in children, are joined together. The two lateral edges of this bone have each one cartilaginous half notch, and five cartilaginous whole notches; the half notches are at the upper part of the lateral edges, and the five entire notches come nearer to each other, in proportion as they are lower, and part of the laſt properly belongs to the third piece.

The third piece, commonly called *cartilago enſiformis*, and *xyphoides*, is entirely cartilaginous in infants, and young ſubjects, but in an advanced age it generally oſſifies, either wholly, or in part. This piece is joined to the lower extremity of the ſecond, between the cartilages of the laſt true ribs, and is often more or leſs notched on each ſide, to form part of the articular notches of the *ſternum*. Its figure and ſize vary, and in ſome ſubjects it is forked, and in others perforated. Sometimes alſo it is very large, and at others very ſmall, hardly exceeding in ſome ſubjects the third part of an inch. The inner ſubſtance of the *ſternum* is almoſt all cellulous, and very tender; it is covered with a thin, but compact lamina. The *ſternum* compleats the fore part of the cavity of the thorax, and ſuſtains the anterior extremities of the ribs; being ſufficiently fixed to reſiſt compreſſions, and other outward accidents, and yet moveable enough, by means of its articulation with the cartilages of the ribs, not to obſtruct the motions neceſſary to reſpiration. It ſerves alſo for the inſertion of ſeveral muſcles, and to ſupport the mediaſtinum. *Winſlow's* Anatomy, p. 67.

We owe to Mr. Hunauld a very judicious account of the perforation which is ſometimes found in the lower part of the *ſternum*.

This perforation is ſometimes larger, ſometimes ſmaller; and a certain German author has found a very ſingular uſe for it, ſuppoſing that it gives paſſage to the mamillary veins and arteries; but Mr. Hunauld, though he had often found the *ſternum* thus perforated, never could obſerve any veſſels paſſing it, but always found it filled up with a cartilaginous ſubſtance. The German author does not poſitively affirm that he ſaw the veſſels paſſing through this perforation, and Mr. Hunauld ſuppoſes it to have been but a conjecture, that this might be its uſe. Its origin and formation, however, may be more rationally accounted for on much ſounder principles.

The *ſternum* is in its firſt ſtate wholly cartilaginous, and the oſſification begins afterwards in ſeveral different parts of it: the number of theſe oſſifying ſpots is wholly uncertain, but as they encreaſe they unite, ſooner or later, into three pieces, and afterwards theſe three pieces unite themſelves, ſo as to form only one. If therefore, when theſe different oſſifications begin to unite, there be ſome place where the oſſification has been impeded, this place, or ſpot, muſt remain only of a cartilaginous ſubſtance, and in making the ſkeleton, this cartilage will be ſeparated from the bones, and will conſequently leave a perforation in the *ſternum*; and what makes this the more probable, is, that this perforation, which is ſo commonly ſeen in ſkeletons, is never found in diſſecting the recent body. It may alſo have happened, that the three pieces of bone, which conſtitute the *ſternum*, by uniting at their edges, may, in acquiring their growth and ſolidity, have naturally left a vacancy between them. We never find a perforation of this kind in the upper part of the *ſternum*, which is probably owing to that part of it being only one piece in the earlier times, and not oſſifying in different places and ſpots at the ſame time; as is always the caſe in regard to this lower part of the *ſternum*, where the perforation is always found. Mem. Acad. Par. 1740.

Cartilages of the Sternum. The *ſternum* of an adult ſubject has commonly ſixteen cartilages; fourteen of the number are articular, the other two are ſymphyſes. Of the former, two belong to the articulations of the clavicle, and twelve to thoſe of the true ribs, from the ſecond to the ſeventh incluſively; and the two ſymphyſes are both between the *ſternum*, and the firſt rib on each ſide. There is likewiſe another ſymphyſis, by which the upper portion of the *ſternum* is connected to the lower; but the cartilage of this is often obliterated in advanced age. The apophyſis enſiformis is often long toward the *ſternum*, and more or leſs cartilaginous toward the other end. This has, in very aged perſons, been ſometimes found entirely oſſified, and ſometimes wholly cartilaginous even in adults. *Winſlow's* Anatomy, p. 149.

Ligaments of the Sternum. The *ſternum* has ſeveral ligaments, by which it is connected to the clavicles and ribs. It is joined to the clavicles by ſtrong ſhort ligaments, fixed by one extremity round the edges of its two ſuperior notches, and by the other in the extremity of each clavicle, and by the middle to the inter-articular cartilages, ſurrounding the particular ligaments which go between the edges of theſe cartilages and the *ſternum*. *Winſlow's* Anatomy, p. 149.

Sternum *fractured*. The *ſternum* is equally ſubject to depreſſions and fractures, from falls and blows, with the reſt of the bones. When either of theſe accidents happen to it, the part is not only uneven and painful, but the ſubjacent arteries and veins are alſo contuſed and ruptured; whence ariſe pains in the breaſt, difficulty of breathing, violent coughs, ſpitting of blood, or elſe extravaſations of it in the

præcordia, or between the duplicatures of the mediaftinum, with many bad fymptoms of the like nature. The figns of a *fractured fternum* will therefore be very evident by thefe, and by its being moveable to the touch, efpecially when one part of it grates againft another, and when there is a cavity and inequality very remarkably vifible there.

In order to reduce a fracture of this bone, the patient muft be laid on his back on a bed, or hard even place, as a table, putting a hard pillow, a large parcel of cloth rolled up, or fome other fuch body, under his back, and preffing down his fhoulders, by which means the *fractured fternum* will be elevated and extended; and to facilitate the reduction, the furgeon muft prefs the bones of the *fternum* together, and fhake them very ftrongly. But when this method is impracticable, or not proper, the fkin muft be divided, and the depreffed part of the *fternum* lifted up into its place, by means of an elevator, or elfe of a fcrew gently wormed into the part, and afterwards pulled upwards; and when it has regained its natural fituation, it muft be kept in it by the proper bandages. If after the reduction violent pains continue under the *fternum*, and if blood fhould gather, and fuppurate internally, between the duplicature of the mediaftinum, the lower part of the *fternum* ought to be trepanned, as the cranium on the like occafions; and when the putrid matter is difcharged, and the wound cleanfed, it muft be healed with vulnerary balfams; and if any blood fhould be found difcharged into the cavity of the thorax, the cure muft entirely depend on the evacuating that by the paracentefis, in the manner of wounds of the thorax. *Heifter*, p. 122.

STHENIA, Σθενια, in antiquity, a feftival of Argos, fuppofed to be kept in honour of Minerva, furnamed Σθενιας from σθενος, ftrength. *Potter*, Archæol. Græc. Tom. I. p. 430.

STIÆ, a word ufed by fome of the old authors for pebbles found on the fea-fhore.

STIBIALIA, a term ufed by fome to exprefs the antimonial medicines.

STIBADIUM, among the Romans, a low kind of table-couch, or bed of a circular form, which fucceeded to the triclinia, and was of different fizes, according to the number of guefts they were defigned for. They were called *hexaclina*, *octaclina*, or *enneaclina*, according as they held fix, eight, or nine guefts, and fo of any other number.

STIBINUS *color*, a term ufed by St. Jerom, and others, to exprefs the falfe black colour which the antient Jews, and other Eaftern people, gave to their eye-brows with *ftibium*, or antimony.

STIBIUM, *antimonium*, antimony. See ANTIMONY, *Cycl.*

This is a mineral never found native in its perfect ftate, but always intimately mixed with, and penetrated by fulphur, and other extraneous matter, and by it reduced to the ftate of an ore. In this condition it is ever found in the earth, and according to the different proportions of fulphur, or other matter, it contains, it affumes very different appearances.

It is moft commonly found in form of a very hard and heavy lead-coloured fubftance, compofed of a number of extremely fmall granules, all very bright and fparkling, and giving it the appearance of a lump of the pureft fteel when frefh broken. This is what is commonly underftood by the name *antimony ore*, and is what is fold under that title in the German fhops.

Not unfrequently, however, it appears of a fomewhat more lax texture, lefs heavy, but much more bright, and compofed of fmall, but vifibly broad and flat particles, of a very pale whitifh lead colour, and glittering appearance, like that of many of the lead ores. This is called *broad-grained antimony ore*.

Sometimes alfo, but lefs frequently, *antimony* appears in form of bright maffes, made up of multitudes of parallel flender filaments, of a bright fteel colour, and more glittering hue than in either of the former ftates: thefe filaments are of different breadths and thickneffes in the feveral maffes. Thefe are generally known by the name of *ftriated*, or *plumofe antimony ore*.

Thefe are the moft natural and fimple appearances of this foffil, but befide thefe it is liable to a multitude of other very different ones, as it fometimes contains iron mixed among its own matter, and very frequently filver; thefe may naturally be fuppofed to give it fome differences in its appearance: but befide thefe it is fubject to much greater, from its admixtures with the common marcafites and pyritæ; thefe often tinge the whole body of the ore to a filvery white, or to a golden yellow.

Antimony ores are found in fiffures and veins at different depths, and often very near the furface, and is varioufly accompanied with fpars, cryftals, fulphurs, and other fubftances. Sometimes the veins of it are every way furrounded by a tolerably pure yellow native fulphur; fometimes with a more debafed matter, made of a mixture of fulphurs, earth and fpar, differing according to the different difpofition and admixture of thefe bodies.

Antimony is found in great abundance in England and Germany; we have feveral mines of it in Cornwall; and Germany, Hungary, and many other parts of the world, afford it in very great abundance.

To reduce it to a ftate fit for ufe, it is to be feparated from its ore by the force of fire, and by the affiftance of fuch ingredients as break the mutual connection between the fulphureous and the reguline part, which mutually diffolving each other, keep the concrete in the ftate of ore. The addition of iron is able to do this; and that of filver, copper, and other metals, has alfo the fame effect.

There have not been wanting perfons, who have pretended to extract a mere running mercury from *antimony*, and Mr. Boyle believed it might be done: but this is one of the many great things pretended to by chemiftry, of which we have yet no fufficient proof.

Antimony, when feparated from its ore, is very eafily fufible, and runs the thinneft of all the bodies of this kind. It greatly promotes the fufion of other foffils, but it makes every thing brittle that it is mixed with. It is of great ufe in medicine, chemiftry, and mechanics, and in its feveral preparations is diaphoretic, cathartic, and emetic. The chemifts ufe it greatly in their operations on other metals, and it is an ingredient in pewter, bell-metal, and the mixt metal, of which types are made for printing. *Hill's* Hift. of Foff. p. 623.

Mr. Geoffroy has been the inventor of a new method of treating this mineral, by which it yields much more regulus than according to thofe prefcribed by Kunkel and Stahl, and is purified without the addition of falts, and with very little lofs.

It is generally fuppofed, that the vapours of *antimony* are poifonous when raifed by fire, but it appears otherwife from the operations this gentleman made on it; the fame operator having once gone through fixty calcinations of twelve ounces of *antimony*, without receiving any harm from it: whence it is very evident, that the common opinion of the fumes of *antimony* containing an arfenical fulphur is an erroneous one; and it may be added, that one great mark of *antimony*'s being good, is, that it lofes a great deal of its weight in calcination. It has more fulphur in this cafe, which the fire raifes in a vapour, and lefs of the terreftrial matter or fpar, which are ufually very abundant in it. It has been proved by experiment, that the fulphur of *antimony* is a neceffary and effential part of its conftruction, fince without this it is no longer emetic; but this fulphur is only neceffary in a certain proportion; for it is found, that when it is more abundant in the *antimony*, the whole lofes in proportion of its emetic quality; and Mr. Geoffroy has found by repeated experiment, that to give this virtue in its greateft degree, the *antimony* is firft to be divefted of its native fulphur, much of which is of no ufe as to this intention, and is then to be melted with a gentle fire in a crucible with a quantity of foap, made from a ftrong lixivium of pot-afhes, quick-lime, and oil, united by boiling into a folid mafs.

The *antimony* melted with this, after a fufficient previous calcination, affords a fort of glaffy cruft of fcoriæ, which covers a quantity of compact regulus lying at the bottom of the crucible. Thefe fcoriæ are a fort of blackifh glafs, which melts in the flame of a candle, but does not run on being expofed to the air. This is plainly compofed of the burnt oil of the foap, united with the acid of fulphur of *antimony*, and a vitrification made with fome earthy particles, and the falts of the foap; this vitrification is what preferves the fatty matter from being liquified by the air. When thefe fcoriæ are feparated from the reguline matter, if that be again melted, with an addition of an alkali falt and of the powder of white cryftal glafs, there is produced a purer regulus than can be obtained by any other known method, and in a larger quantity, by two ounces from the pound, than ever Stahl, or Kunkel, were able to procure. Mr. Geoffroy, by thefe nice obfervations and experiments, difcovered that *antimony* contained much lefs common fulphur than had been generally fuppofed, fince it can be made to lofe, at the utmoft, only three ounces and five drachms in the pound in calcination. The emetic quality of the regulus proves, however, that it yet contains a very large fhare of fulphur, though of another kind: this Mr. Geoffroy diftinguifhes from the common fulphur, by the name of the *metallic fulphur*. Mem. Acad. Scienc. Par. 1736.

Acid of ANTIMONY. Mr. Charras was the firft author who gave the world a fuccinct method of drawing an acid liquor from *antimony*. He did it thus: he mixed crude *antimony* ore in powder with three times its weight of fand, this he diftilled in a large retort into a capacious receiver, filled half full of river water, and on rectifying this, the acid liquor was to be produced. Himfelf acknowledges, however, that this, though a fuccinct, is not always a certain method, for that fometimes the acid liquor was produced, and fometimes not: this, however, he attributes wholly to the management of the fire, which he fays will always afford the acid, if conducted regularly through its feveral degrees. But Mr. Homberg trying this experiment feveral times, and finding it fometimes fucceed, and at other times not, though the fame cautions were ufed, difcovered at length that this variation,

riation, in the ſucceſs of the proceſs, was not occaſioned by any difference in the fire, but by the different nature of the matter employed. The crude ore of *antimony* ſometimes being mixed with a white argillaceous earth, and ſometimes free from this admixture; he found, that when it had this white earth in any great proportion, it never failed to yield this acid liquor; and that when it had none of it, it never could be made to yield a drop of acid; and conſequently, that this was not an acid extracted from *antimony*, but merely from the earth, as common pipe-clay, or any of our argillaceous earths, will yield an acid by means of a ſtrong fire.

This liquor had therefore been very improperly called the *vinegar of antimony*; and it is evident, that whatever acid *antimony* contains, muſt be of the nature of ſpirit of ſulphur, ſince ſulphur ſo greatly abounds in the compoſition of that mineral, and its ſulphur is wholly the ſame with the common brimſtone. Whatever acid, therefore, of this kind could be produced, muſt be of the nature of that collected from the fumes of burning ſulphur; and, even though it were produced from *antimony*, could have nothing of the nature of *antimony* in it, ſince it would be wholly the produce of the common ſulphur in that mineral, and not of the reguline part, which alone is properly *antimony*. Experiment alſo proves the truth of this opinion, the *acid of antimony*, truly ſeparated from it, being no way different, in any particular, from that of crude ſulphur.

There are ſeveral ways by which it may be made, but the following ſeems the eaſieſt and moſt familiar. Powder crude *antimony* very fine, lay it in an earthen diſh not glazed, and of a conſiderable width at the top; cover this diſh with an earthen pot, with the bottom taken out, and fit to this three earthen aludels, and cover the mouth of the uppermoſt aludel with a large glaſs bell; the edges of which muſt be ſuſtained about a quarter of an inch above a veſſel of water, kept ſo hot, as to fumigate the inſide of the bell; the water that runs down from the bell, will be received again into the veſſel of water. In the middle of the earthen pot, which covers the diſh of *antimony*, there muſt be a hole, large enough to admit the handle of an iron ladle, or ſome ſuch other inſtrument, to ſtir about the *antimony*. The fire being made under the earthen diſh, and continued a proper time, there will be found the flowers of *antimony* in the aludels, a little acid liquor in the water of the veſſel kept under the bell, and the *antimony* will be found calcined in the diſh.

It is but little acid that can be obtained in this manner, but then it is aſſuredly the pure acid of the ſulphur of *antimony*. Sometimes this method furniſhes alſo little or no acid, but this depends on the care of the operator, and the temperature of the air; for the colder and moiſter the ſeaſon is, the more acid will be obtained, and the hotter and drier it is, the leſs. The operation, whenever ſo perfect, is however of little value, the acid being every way the ſame with that of common ſulphur. Mem. Acad. Par. 1700.

Infuſion of ANTIMONY. Mr. Homberg being well aſſured, that water was a menſtruum capable of diſſolving all the metals, if properly applied, uſed it, in ſeveral different manners, in his analyſis of *antimony*. He made an *infuſion of antimony* in water, putting into ſeveral glaſs veſſels crude *antimony*, coarſely powdered, five pounds into each veſſel, and to each of theſe quantities he added two pints of rain water; after the *antimony* had ſtood thus for ſix months, the ſeveral parcels were uſed on different occaſions, one only excepted, which had been forgotten, and had at length ſtood two winters and a ſummer: having at length found this veſſel, he obſerved that its inſide was every where coated over with configurations of leaves; he at firſt ſuppoſed this to be owing to ſome ſalts of the *antimony*, which had been diſſolved in the water, and had afterwards cryſtallized themſelves in this manner, as the butter of *antimony* is ſometimes known to do in ſublimation; but on rubbing the ſides of the veſſel with a finger, and afterwards ſcraping them with a knife, he found that they were covered with a yellowiſh pellicle, without the leaſt appearance of ſalt, and that the configurations of the leaves were not raiſed upon this pellicle, but ſunk, as if graved by a tool. The water taſted ſomewhat acid, and being tried on turnſol, and on different metallic ſolutions, it turned the turnſol to a light red, and turned a ſolution of ſilver white; whence it appeared to be an acid, and of the nature of that of ſea-ſalt. The ſunſhine had turned this water ſower, had made it act upon the *antimony*, and take up a part of its ſalt. This ſalt, in the winter, was probably afterwards concreted into the figures of leaves, formed upon the mud depoſited by the water on the ſides of the veſſel; and theſe ſalts being afterwards diſſolved again in ſome hotter weather, had eaten their way into this ſediment of mud, in the form of the leaves, &c. in which they had concreted. Mem. Acad. Par. 1693.

Texture of STIBIUM. Monſieur de Reaumur gives the following account of the contexture of *antimony*, or *ſtibium*.

Nothing is more common, than to obſerve on the ſurface of broken *antimony* long and ſhining needles, as it were; and that *antimony*, on which theſe are moſt diſtinct and viſible, is eſteemed the beſt. Sometimes theſe ſtreaks are ranged with ſo much order, and branch out ſo regularly in certain directions, that thoſe who are ever ſo converſant with it, cannot but admire its beauty. The figures of the conſtituent molecules of this mineral may poſſibly contribute ſomething to the formation of theſe needles, but the texture, and configuration of the conſtituent parts, will not alone account for the diſpoſition of theſe ſtreaks, and their arrangements, in regard to one another; ſince upon breaking different lumps of the ſame *antimony*, and thoſe of the ſame ſhape, we frequently obſerve quite different configurations of the needles. Let us take, for inſtance, equal maſſes of *antimony* of a regular conic figure, theſe being moſt frequent, from the ſhape of the veſſel they cool in, which reſembles a funnel, or inverted cone; let ſeveral of theſe conical maſſes be broken into different parts, and we ſhall ſee the needles in very different directions in theſe ſeveral parts.

In one of theſe maſſes, from a certain height, we may obſerve all theſe needles directed to the point of the cone; in a piece taken from a little higher, the needles ſhall be horizontal, or nearly perpendicular to the former; above theſe we ſhall find others, which ſometimes direct themſelves toward ſome point in the baſe of the cone, and ſometimes form themſelves into different cones with their ſeveral ſummits.

In another of theſe maſſes we ſhall not find the needles diſpoſed into a horizontal direction, but running into ſmall conical parcels, in directions quite reverſe one to another; that is, ſome of them ſhall have their ſummits toward the baſe of the cone, and others toward its apex. In ſome lumps alſo we ſhall diſcover needles every where, and in others no where at all; and often the needles are found in one part of the lump, with no appearance of them in the others. Sometimes alſo we ſhall find the inſide of a maſs regularly diſpoſed into cones, though the outſide is of no ſuch figure, for the internal cones have no dependance upon the external figure of the maſs; and ſometimes the needles are diſpoſed along the ſides of the cone, and their direction ſeems to follow the ſides of the veſſel in which they were fixed. Notwithſtanding, however, all theſe varieties in form, the cauſe of all the appearances is wholly the ſame, and is no other than that refrigeration, by which the maſs is changed from a fluid into a ſolid ſtate; and to the progreſs of this the needles plainly owe their different directions.

All melted metals cool firſt at the tops and ſides, and thence by degrees through the whole body of the maſs: the particles at the ſides and top, which firſt cool, becoming fixt to thoſe which are neareſt them, affix thoſe, and they are the next that cool, and ſo on, in ſucceſſive order; now moleculæ, of whatever ſhape, thus affixed ſucceſſively to each other, form a kind of threads or needles, the ſeveral directions of which ſhew the order in which the refrigeration has been carried on.

If the crucible, or other veſſel, in which the melted *antimony* is ſuffered to cool, were in the ſhape of a hollow bowl; if its ſides were every where equally thick, and equally warm, and acted equally upon by an air equally cold; and if the melted ſubſtance were of the ſame uniform nature, alſo, in all its parts, all the needles or fibres would be then ſo many rays, terminating in the center of the bowl; and if the ſubſtance were ſuch, that its fixed particles were naturally all of a length, we ſhould find ſo many concentrical beds of needles, formed by parcels of each ray, and lying at equal diſtances from the center.

But ſo many regular circumſtances do not concur in the cooling of melted *antimony*; and hence the beforementioned irregularities muſt neceſſarily ariſe. In melting *antimony* in conical crucibles, and ſuffering it to cool in them, the needles may be determined ſeveral ways, to any directions one may chooſe.

If, when the crucible is taken from the fire, it be ſet to cool upon ſome cold body, the conſequence is, that the bottom and top of the *antimony* muſt cool firſt, and the needles will be found diſpoſed into two cones, the one having its baſe at the apex, and the other at the baſe of the large, or general cone: but if the crucible be ſet on burning coals, and the ſurface of the *antimony* covered with more coals, then the ſides muſt cool firſt, and the needles will be found running horizontally, or forming themſelves into horizontal cones: the touching the ſides of the crucible alſo, at times, with a wet cloth, and by that means forcing the melted matter to cool firſt in ſuch particular places, will give cones of needles directed horizontally, and having their baſes at thoſe ſpots of the crucible ſo forcibly cooled.

Not unfrequently there is found a hollow in the midſt of a conical maſs of *antimony*, and in that caſe there are ever found needles proceeding in different directions from the ſides of that cavity inwards, as they, when cooled, became of the ſame nature with the ſides of the veſſel, and acted on the encloſed maſs in the very ſame manner.

To procure the needles perfect and fine, the *antimony* muſt be ſuffered to cool gradually, for if it cool too faſt, one molecula becomes fixed before it can be adapted to the end of another, and the whole is a confuſed maſs; and the ſame happens alſo if it cool too ſlowly; for then the particles of fire

fire get out ſo very regularly and inſenſibly, that the moleculæ cooling equally all together, form no arrangements. This is found by letting a crucible of melted *antimony* ſtand on ſome burning coals, and gradually cool as their heat burns away and decreaſes; in which caſe the maſs will have perhaps no needles at all, or if any, then but very few.

It may be objected to this, that if the refrigeration of the maſs is the only cauſe of the needles in *antimony*, all melted metals ought to afford the ſame appearance alſo, if cooled in the ſame manner: and poſſibly indeed all do ſo; we ſee them eaſily in *antimony*, becauſe it breaks with a ſlight blow, without diſordering the configuration of its parts, the combinations of its molecules into needles being more firm than that of the needles to one another; but in metals which require more force to break them, the needles may perhaps rather break than ſeparate, and by more force muſt be more diſordered; and all the parts may be as regularly arranged in a ductile maſs, as in a brittle one, though we are not able to diſcover that arrangement.

Lead, when hot to a proper degree, ceaſes to be ductile, and is brittle, and lead broken at this juncture is found to be granulated, appearing like broken ſteel; there is no reaſon to doubt but that this is alſo the caſe, when that metal is perfectly cold, but that the force required to ſeparate, or break it, deſtroys its proper ſtructure.

Mr. Reaumur melted lead in a conical crucible, and ſuffering it to cool to a certain degree only, he broke the maſs into ſeveral large lumps by a ſmart blow of a hammer, and in theſe found the ſame needles as in *antimony*, the granules having cohered in long trains, juſt as the moleculæ of the *antimony*; and the diſpoſitions of the ſeveral groupes of needles in the lead, in regard to the ſides and bottom of the crucible, were the very ſame with thoſe of *antimony*. But there is this manifeſt difference between the needles of lead, and thoſe of *antimony*, that whereas the latter are flat and extremely gloſſy, the former are viſibly round, and much leſs bright. Mem. Acad. Scienc. Par. 1724.

Ore of Antimony. The way of running down *antimony* out of its ore by the aſſayers, is as follows. Take a crucible that will hold ſome pounds of *antimony* ore, broken into pieces of the ſize of a hazel-nut, and bore at the bottom of it a few ſmall holes with a common gimblet; place this bottom in the mouth of another ſmaller crucible, put in the ore, and cover the orifice with a tile; then lute all the junctures, and place this on the pavement of the hearth, making a circle of ſtones all round it, at ſix inches diſtance; fill this intermediate ſpace with aſhes, ſo high, that the lower pot may be covered up to its rim, then put freſh burning coals upon the whole, and blow the fire ſtrongly with a pair of hand-bellows, to make the upper veſſel red-hot: when it has been ſo a quarter of an hour, take away the fire, and when the veſſels are cold, open them, and the *antimony* will be found in form of a regulus in the under veſſel. *Cramer's* Art of Aſſaying, p. 356.

The moſt ready method of fuſing *antimony*, yet known, is by means of that mineral ſubſtance called *cawk*. A lump of this, of the bigneſs of a wallnut, thrown red-hot into a pound of *antimony* in fuſion, converts almoſt the whole ſubſtance of it into glaſs, fifteen ounces of clean and fine glaſs being thus produced; and what is very remarkable, the cawk itſelf never melts in the metal.

The purification of gold, by means of *antimony*, is performed in this manner. Before you enter on the proceſs, it is neceſſary to gueſs, as nearly as may be, at the allay of the gold, by the touch-needles, or otherwiſe. If the quantity of gold in the maſs is not leſs than three quarters, that is, eighteen carats, the maſs muſt be melted in a wind-furnace, and the crucible muſt be covered, to prevent coals falling in; this done, put into it, at ſeveral times, double the quantity of crude *antimony* in fine powder, as ſoon as one portion of the *antimony* is melted, putting in another: let the whole continue in fuſion a few minutes, then pour it into a melting cone, warmed, and rubbed with tallow, and ſtrike with a hammer on the floor, near where the cone ſtands, that the heavier part may ſink to the bottom. When all is cold, invert the cone, and ſtrike it, and a maſs will fall out, having at bottom a regulus, more or leſs yellow, according to the quantity of the gold in the mixture; this may with a few blows be ſeparated from the ſulphureous cruſt, which is at top. Melt in a ſmaller fire this regulus, and when in fuſion add to it a double quantity of crude *antimony* in powder, and pour it out into the cone again a little after; ſeparate the regulus from the *antimony* at top, and then repeat this operation once more. When this is done, put the ſeparated regulus into a thick good teſt, place this in the furnace immediately before the bellows, put coals round it, and one or two pieces of wood upon them, and make a middling fire, ſuch as is ſufficient to melt the regulus, the reguline part of the *antimony* will vaniſh in a thick ſmoak; then encreaſe the fire, and keep it ſo, till the fumes are over, and the ſurface of the gold is of a fine green; and afterwards give the gold another fuſion with borax and nitre, and it will be perfectly pure.

When the gold to be purified by this proceſs is impure to an allay of eight carats, it is not proper to perform the precipitation by *antimony* alone, but there ſhould be added as many times two carats of common ſulphur, as the allay of the gold is ſo many carats leſs than eighteen. *Cramer's* Art of Aſſaying, p. 276.

Stibium, in medicine, &c. is not only given in ſubſtance, but many preparations of it are alſo uſed; which are either emetic, cathartic, diaphoretic, or ſudorific. Crude *antimony* in powder is found good for diſſolving viſcidities, in cutaneous diſeaſes, and, as ſome very confidently aſſert, in convulſions and epilepſies. Externally, in ointments, it is commended for drying up ulcers, curing the itch, and in plaiſters for reſolving of tumors.

There appears no reaſon for people's being afraid of giving crude *antimony* internally, experience ſhews it to be a ſafe medicine, unleſs by accident the acid of the ſtomach ſhould prove ſtrong enough to be a menſtruum to it.

The preparations of *antimony* are, 1. *ſulphur præcipitatum antimonii*. 2. *Crocus antimonii*, called alſo *crocus metallorum*. 3. *Crocus antimonii lotus*. 4. *Calx antimonii*, called *antimonium diaphoreticum*. 5. *Tartarum emeticum*. 6. *Cauſticum antimoniale*. 7. *Cinnabaris antimonii*. 8. *Regulus antimonii martialis*. 9. *Tinctura antimonii*. 10. The *Kermes* mineral, or Carthuſian powder. See the articles Sulphur, Crocus, Calx, &c. *Cycl.* and *Suppl.*

The virtues of *antimony*, in the diſeaſes of animals, are very great, and very evident on any trial. Pigs that have the meaſles are at all times recovered by it, which proves it a great purifier of the blood. Horſes who have running heels, that cannot be cured by the common methods uſed by the farriers, will generally be cured by this medicine in a little time. The manner of uſing it is this: mix one drachm with every feeding of oats which the horſe has in a morning; it is beſt put together in one place, buried under a few oats, and the horſe's head being with-held a little, and then let go juſt againſt that place, he will take it all in at a mouthful. Some horſes do not diſlike it, others obſtinately refuſe it, but to theſe it may eaſily be given in balls. The virtues of this drug, in fattening of cattle, has by many been thought imaginary, but experiment proves it to be a real truth. A horſe that is lean and ſcabby, and not to be fatted by any other means, will become fat on taking a doſe of *antimony* every morning, for two months together. A boar fed for brawn, and having an ounce of *antimony* given him every morning, will become fat a fortnight ſooner than others put into the ſtye at the ſame time, and fed in the ſame manner, but without the *antimony*. Philoſoph. Tranſ. Nº 39.

Crude *antimony* is recommended in palſies, pains, and numbneſs, which come on after a ſalivation, and is ſaid to have cured ſeveral who were paralytic from other cauſes. The method of giving it, is to begin with three grains, increaſing the doſe with three grains every day, to half a drachm; after which the doſe is diminiſhed three grains every day, till it comes down to the quantity of the firſt doſe. Commerc. Liter. Norimb. ap. Medic. Eſſ. Edinb.

Antimony, before the twelfth age, was of ſervice only in the compoſition of paint. Scripture deſcribes it to us as a ſort of paint, with which the women blackened their eyebrows. Jezabel underſtanding that Jehu was to enter Samaria, painted her eyes with *antimony*, or, according to the Hebrew, put her eyes in *antimony*.

As large black eyes were thought the fineſt, they of both ſexes, who were careful of their beauty, rubbed their eyes, eyelids, and round the eyes, with a needle dipped in a box of paint made of *antimony*, with a deſign of blackening them.

At this day the women of Syria, Arabia, and Babylonia, anoint and blacken themſelves about the eyes; and both men and women put black upon their eyes in the deſert, to preſerve them from the heat of the ſun, and the piercing of its rays. M. Darvieux tells us, that the Arabian women border their eyes with a black colour made of tutty, which the Arabians call *rebel*. They draw a line of this kind of blacking without the corner of their eyes, to make them appear larger. Iſaiah, in his enumeration of the ſeveral ornaments belonging to the daughters of Sion, has not forgot the needles which they made uſe of in painting their eyes and eyelids; nor has this practice eſcaped the laſh of Juvenal [b].

> *Ille ſupercilium madida fuligine tinctum*
> *Obliqua producit acu, pingitque trementes*
> *Attollens oculos.*

Ezekiel, diſcovering the irregularities of the Jewiſh nation under the idea of a debauched woman, ſays, that ſhe bathed, perfumed herſelf, and that ſhe anointed her eyes with *antimony*. Job ſhews ſufficiently how much *antimony* was in eſteem, by calling one of his daughters a veſſel of *antimony*, or a box to put paint in, *cornu ſtibii*. Tertullian and St. Cyprian have declaimed very warmly againſt this cuſtom of painting their eyes and eyebrows [c].—[[b] *Juv.* Sat. 2. [c] *Calmet's* Dictionary.]

STIBIUM *ceratum.* See the article VITRUM *antimonii ceratum.*

STICA, a name given by some authors to all external astringents used in hæmorrhages.

STICA, in our old writers, a brass Saxon coin, of the value of half a farthing, four of them making an helfing. *Blount.*

STICHOMANTIA, Στιχομαντεία, in antiquity, a sort of divination by verses, (commonly those of the Sibylline oracles) which being wrote on little pieces of paper, and thrown into a vessel, the first drawn out was supposed to contain the will of the Gods. *Potter*, Archæol. Græc. Tom. I. p. 333. See SORTES, *Cycl.*

STICHOS, a name given by the old writers to a pectoral confection, the principal ingredient of which was the herb *marrubium*, or hore-hound.

STICKLEBACK, in ichthyology, a name given by us to that small fish, called by authors by the several names of *spinachia, spinax*, and *pugnitius piscis*; as also *pisciculus asper, pisciculus aculeatus*, and the like; and finally, by Artedi, by the much more expressive name of *gasterosteus*, expressing that great singularity it has in the bony structure of its belly. The common *stickleback* is distinguished by Artedi by the name of the *gasterosteus* with three spines on the back; and by this character it differs from two other species, the one the *spinarella* of authors, a small species with ten prickles in the back; and the other a long sea kind with fifteen spines on its back, called by Willughby, and others, the *pugnitius marinus longus.* See the article GASTEROSTEUS.

As contemptible a fish as this may seem, its mischief in eating the young fry in ponds is not greater than its value. In a sort of manufacture carried on at Boston, and some other parts of Lincolnshire, they have fallen into a way of making oil of it, and have made annually a hundred tun, or more, to their very great advantage. All the waters thereabout swarm with this little fish, and doubtless a sufficient quantity might be found in other places for the same sort of use. They grow in the Boston river to an inch and half in length, and about half an inch in breadth, and are taken out at a bushel a draught. Eight chalder of them make a barrel of oil; their barrel is a hogshead; they are obliged to use them very fresh, else the oil runs from them to waste, and they usually boil every night what they have caught by day. It is a wonder that this quality of this little fish was not found out sooner, for in frying them in the common way for eating, they all run into an oil in the pan. Philos. Trans. N° 223.

STICKLER, in our old writers, an inferior officer, who cut wood within the king's parks of Clarendon. Rot. Parl. 1 Hen. VI. *Blount.*

STICKS *of eels*, a quantity, or measure of twenty five. A bind of eels contains ten *sticks*, and each *stick* twenty five eels. Stat. Weights and Measures. *Blount.*

STIFFLE, or GREAT *muscle*, in the manege, is the part of the hind leg of a horse which advances towards his belly. This is a most dangerous part to receive a blow upon.

STIGMA, among botanists. See the article PISTIL.

STIGMATA, in natural history, the apertures in different parts of the bodies of insects communicating with the tracheæ, or air vessels, and serving for the office of respiration. *Reaumur*, Hist. Insect. passim.

Nature has given to these minute animals a much larger number of tracheæ and bronchia, than to us. We have the ramifications of the trachea reaching no farther than into the breast, whereas, in the bodies of these insects, we find them extended through the whole, and finely and admirably interlaced one with another. We have but one mouth to respire by; and the organization of the parts, inservient to respiration, is very admirable in us; but in the insect class, the mouths, or openings to breathe at, are much more numerous, and the organization much more complex.

All the two-winged and four-winged flies, which have a single or undivided corcelet, to which their legs are all fixed, have also four *stigmata* in that corcelet, two on each side. They have them also on the rings of their body, but those on the corcelet are the most considerable.

Of the four on the corcelet, the two anterior ones are usually the largest. The best way to find them, in the generality of flies, is to examine them first in the larger species of the libellæ, where they are very distinct and plain, and after their situation is well known in that species, they will be much the more readily found in the rest.

These *stigmata* of the corcelet, as well the anterior as the posterior, are oblong, and placed obliquely to the length of the body; that end of them next the head is more elevated than the other, and their size is sufficiently large to render them visible, especially the first pair. Each of these seems not a little to resemble a sea-muscle with its shells a little open, or is somewhat like the opening of an eye. It is also surrounded by two eyelids, proportionably thick; and beside these, which make its outer circumference, one may discover two others within, which are bordered with hairs, and which, when closed, often quite shut up the opening.

The colour of the *stigmata* often is some help also to us for the discovering them; they are very frequently different in colour from the corcelet; some are yellowish, others of a coffee colour, or some degree of a fallow colour, in flies whose corcelet is brown, or black, or bluish.

Flies have, beside these, several *stigmata* also in the rings of their bodies, perhaps in every one of them, though commonly those in the two or three first are only to be distinguished: these are not like those of the corcelet, but are round, usually a little eminent above the rest of the surface, and resembling pin's heads; they are not easily discovered, because they are not only small, but usually hid by the folds, or commissures of the rings. They are usually two on each ring, placed on the two opposite sides, and partly under the belly. *Reaumur*, Hist. Ins. Vol. 4. p. 248.

STIGMATICI, among the Romans, were servants marked in the face for some crime. *Pitisc.* in voc.

STIGMATIZING, among the antients, was inflicted upon slaves as a punishment, but more frequently as a mark to know them by; in which case, it was done by applying a red-hot iron, marked with certain letters, to their foreheads, till a fair impression was made, and then pouring ink into the furrows, that the inscription might be the more conspicuous. *Potter*, Archæol. Græc. Tom. I. p. 64.

STIGMATIZING, among some nations, was looked upon as a distinguishing mark of honour and nobility. *Potter*, loc. cit. p. 65.

STIL *de grain*, in the colour trade, the name of a composition used for painting in oil or water, and is made of a decoction of the lycium, or Avignon berry, in alum-water, which is mixed with whiting into a paste, and formed into twisted sticks. It ought to be chosen of a fine gold yellow, very fine, tender, and friable, and free from dirt. *Pomet's* Hist. of Drugs, p. 14.

STILE (*Cycl.*)—In a philosophical *stile*, the only end is accurately to explain our thoughts to others; thence the particular rules to be observed by a philosopher, in delivering his doctrines, naturally follow: such as,

1°. Not to deviate from the received significations of terms.

2°. That the same terms be always taken in the same sense.

3°. To fix the meaning of such words as have only a vague sense.

4°. To signify objects, essentially different, by different names.

From these rules, the use and necessity of terms of art appear, and shews with how little reason they are vulgarly condemned.

5°. The philosopher ought always to make use of proper expressions, and use no more words than what are precisely necessary to establish the truth of his doctrines. *Wolf*, Disc. Prælim. Logic. cap. 5.

STILL-*bottoms*, in the distillery, a name given by the traders to what remains in the *still* after the working the wash into low wines.

These *bottoms* are procured in the greatest quantity from the malt wash, and are of so much value to the distiller in the fattening of hogs, &c. that he often finds them one of the most valuable articles of the business. They might also be put to other uses, such as the affording a large proportion of an acid spirit, an oil, a fuel, and a fixed salt; and with some address, and good management, a vinegar, and a tartar. Another very advantageous use of them, is the adding them to the next brewing of the malt for more spirit: the encrease of the produce from this, is more than could easily be conceived. It also more readily disposes the new wash to ferment, and gives the spirit a vinosity that it cannot have without it; the proportion, in this case, must never exceed that of a fifth, or sixth part of the whole quantity of liquor employed.

The liquor left behind in the *still*, after the rectifying the low wines into proof spirit, is also called by some by the name of *still-bottoms*; but this is little more than mere phlegm, or water impregnated with a few acid, and some oily parts, not worth separating, unless for curiosity. The liquor left in the *still*, after the rectifying the proof spirit into alcohol, is also of the same kind.

The *bottoms* of melasses spirits seem calculated for many uses. It is very probable that the vinegar-makers would find their account in the trying them, and the strong, and lasting yellow colour, with which they tinge the hands, may recommend them to the dyers. A small proportion of them added to the new treacle to be fermented, greatly promotes the operation, and encreases the quantity of spirit.

The *bottoms* of the wine spirit, that is the remainder, after distilling the spirituous part from damaged wines, or wine lees, may be brought to afford Mr. Boyle's acid spirit of wine, and that substance called by Becher the *media substantia vini.* A parcel of tartar may also be procured in very great perfection; and the last remainder may be converted into excellent and genuine salt of tartar. The liquor may otherwise be serviceable in making vinegar and white lead. *Shaw's* Essay on Distillery.

STILL-*house.* The Dutch have much the advantage of us in the structure of their *still-houses*, and have every thing in

great readineſs and neatneſs. The general rules, in building theſe *houſes*, ſhould be theſe.

The firſt caution is to lay the floor aſlope, not flat, where any wet work is to be performed; it ſhould alſo be well flagged with broad ſtones, ſo that no wet be detained in the crevices, but all may run off, and be let out at the drains made at the bottom and ſides.

The *ſtills* ſhould be placed abreaſt on that ſide of the *ſtill-houſe* to which the floor has its current. The largeſt *ſtills* in Holland, for their greateſt works, are never of that monſtrous ſize that we ſee them of in England, but much more manageable and handy, as ſeldom containing more than ſix or eight hogſheads; and with ſuch *ſtills*, a ſingle hand will perform much more buſineſs than with one of a much larger ſize. Fronting the *ſtills*, and adjoining to the back wall, ſhould be a ſtage for holding the fermenting backs, and theſe being placed at a proper height, may empty themſelves, by means of a cock and a canal, into the *ſtills*, which are thus charged with very little trouble.

Near this ſet of fermenting backs ſhould be placed a pump or two, that may readily ſupply them with water by means of a trunk, or canal, leading to each back. Under the pavement, adjoining to the *ſtills*, ſhould be a kind of cellar, wherein to lodge the receivers, each of which ſhould be furniſhed with its pump, to raiſe the low wines into the *ſtill* for rectification; and through this cellar the refuſe waſh, or *ſtill*-bottoms, ſhould be diſcharged by means of a hoſe, or other contrivance. Theſe are the principal things to be regarded in the erecting a *ſtill-houſe* for the original production of ſpirits, and if theſe rules are well obſerved, malt ſpirit will be made with little more trouble than melaſſes; for by this means the buſineſs of brewing and cooling the waſh, which, according to the method generally practiſed in England, takes up ſo much time and trouble, is entirely ſaved, fermentation is carried on to a much greater advantage, and the quantity of ſpirit encreaſed. *Shaw*'s Eſſay on Diſtillery.

STINT, in zoology, the name of a ſmall bird common about the ſea ſhores in many counties of England, and ſeeming to be the ſame with the *cinclus prior* of Aldrovand, and the *ſchœniclos*, or *junco* of Bellonius, called by the French *alouette de mer*, the *ſea-lark*.

It is ſomewhat ſmaller than the common lark, and in ſhape reſembles the ſmaller ſnipe. Its beak is black, ſlender, and ſtrait; its feet of a greeniſh, or browniſh black; its back is a grey, variegated with oblong black ſpots, and its wings ſomewhat of a reddiſh brown; its neck is grey, and its head variegated with black and a reddiſh brown; its wings are long, and when folded reach beyond the end of the tail; and its rump is ſomewhat reddiſh with black ſtreaks. *Ray*'s Ornitholog. p. 226.

STIP *viſch*, in zoology, a name given by the Dutch in the Eaſt-Indies to a fiſh of the claſs of our European ones which have two back fins, the anterior of which is prickly, the hinder not ſo. Its ſkin is ſpotted, and its fleſh very delicate, and well taſted. It is generally caught by hooks. *Ray*'s Ichthyogr. Append. p. 8.

STIRRUP, (*Cycl.*) in the manege. To looſe one's *ſtirrups*, is to ſuffer them to ſlip from the foot.

The *ſtirrup-foot* is the near, or left foot before.

Stirrup-leather is a thong of leather, deſcending from the ſaddle down by the horſe's ribs, upon which the *ſtirrups* hang.

Stirrup-bearer, called in French *porte etrier*, is an end of leather made faſt to the end of the ſaddle, to truſs up the *ſtirrup* when the rider is alighted, and the horſe ſent to the ſtable.

STIRRUP *of a ſhip*, a piece of timber put upon a ſhip's keel, when ſome of her keel happens to be beaten off, and they cannot come conveniently to put, or fit in a new piece; then they patch in a piece of timber, and bind it on with an iron, which goes under the ſhip's keel, and comes up on each ſide of the ſhip, where it is nailed ſtrongly with ſpikes; and this they call a *ſtirrup*.

STOÆ, Στοαι, in antiquity, the porticos at Athens. Theſe were full of exedræ, ἐξέδραι, and ſide-buildings, furniſhed with ſeats fit for ſtudy or diſcourſe. Here it is probable philoſophers, and their ſcholars, uſed to meet. *Potter*, Archæol. Græc. lib. I. cap. 8. Tom. I. p. 38. See the article EXEDRÆ, *Cycl.*

STOAKED, in a ſhip. When the water in the bottom cannot come to the well of the pump, they ſay, *the ſhip is a-ſtoak*, or *ſtoaked:* ſo they ſay alſo, *the limber holes are ſtoaked*, when the water cannot paſs through them; and that *the pump is ſtoaked*, when ſomething is got into it which choaks it up, ſo that it will not work.

STOAT, in zoology, the name uſed by many for the animal whoſe ſkin is the ermin. See the article ERMINEUM *animal.*

STOC *and ſtovel*, in our old writers, a forfeiture where any one is taken carrying *ſtipites* and *pabulum* out of the woods; for *ſtoc* ſignifies ſticks, and *ſtovel* pabulum. Antiq. Chart. ap. *Blount.*

STOCK *of an anchor.* See the article ANCHOR.

STOCK-*bricks.* See BRICK-*making.*

STOCK-*fiſh*, in the fiſh trade, a name given to the common cod-fiſh when cured in a particular manner, which makes it neceſſary to beat it with ſticks before it is fit for dreſſing. *Willughby*'s Hiſt. Piſc. p. 166. See COD-*fiſh.*

STOCK-*July-flower.* See the article LEUCOIUM.

STOCKER, in ichthyology, a name given by the Germans to the *ſaurus* of the antients, the *trachurus* of the later writers. It is a ſpecies of the *ſcomber*, known among us under the name of the *horſe-mackrel*; and is diſtinguiſhed from the reſt by Artedi, by the name of the *ſcomber* with the lateral line prickly, and with thirty rays in the pinna ani.

STOCKS (*Cycl.*)—STOCKS, among ſhip-carpenters, a frame of timber and great poſts, made aſhore to build pinnaces, ketches, boats, and ſuch ſmall craft, and ſometimes ſmall frigates. Hence we ſay, *a ſhip is on the ſtocks*, when ſhe is a building.

STOCKS, *cippus*, a wooden machine to put the legs of offenders in, for the ſecuring of diſorderly perſons, and by the way of puniſhment in divers caſes ordained by ſtatute, &c. And it is ſaid that every vill, within the precinct of a torn, is indictable for not having a pair of *ſtocks*, and ſhall forfeit 5 *l.* Kitch. 13.

STOMACACE, a word uſed by ſome authors to expreſs a ſymptom of the ſcurvy, which is a fœtor of the mouth, with a ſoreneſs and bleeding of the gums.

STOMACH (*Cycl.*)—In order to underſtand the action of the *ſtomach*, in turning the aliments into chyle, we are firſt to thoroughly conſider its form. It is eaſy to obſerve, that the two orifices of the *ſtomach*, the œſophagus, and pylorus, are not ſituated exactly over-againſt one another; but that if the *ſtomach* be regularly divided longitudinally into two halves, the œſophagus will be found wholly in the anterior half, and the pylorus, in great part, in the poſterior. Near the inſertion of the œſophagus there are two planes of muſcles, the one is placed near the bottom of the *ſtomach*, and encompaſſes all that part of the œſophagus that is neareſt that part. This muſcle throws off obliquely ſeveral bundles of fibres, which run to the middle, both of the anterior and poſterior ſides of the *ſtomach*, and many of theſe extending even to the lower part of it, make what are there called *the oblique fibres of the ſtomach.* The other muſcular plane encloſes, in the ſame manner, the other part of the mouth of the œſophagus, or that which lies toward the pylorus; this terminates on each ſide near the bottom of the *ſtomach.* Theſe two planes of fibres are, as it were, two fleſhy bands about the mouth of the œſophagus, which croſs one another both on the upper and under part of the *ſtomach.*

The longitudinal fibres are very ſlender, and appear about an inch from the pylorus, extending themſelves along both the anterior and the poſterior ſides of the *ſtomach*, quite to the orifice of the œſophagus; and finally, they are inſerted round about the pylorus by two ligamentary bands, which authors have generally paſſed over without obſerving. Theſe bands are much like thoſe of the colon, and occupy all the length of the neck, and may be eaſily diſtinguiſhed by the touch, and are not difficult to be ſeen on bending the part in an inflated *ſtomach.*

The fibres of the bottom of the *ſtomach*, when nicely examined, are found to be circular, all compoſing ſeveral ſmall concentric circles, each ſeries of which is independent of all the reſt. There is one of theſe circles placed juſt in the center of the bottom of the *ſtomach*, and from this the other circles ſpread, being of ſeveral different diameters, according to the places where they ſtand, and reaching to near the orifices where the fleſhy fibres take another courſe, as before obſerved. The bodies, called *circular fibres of the ſtomach*, and ſuppoſed to part from the upper part of the *ſtomach*, cloſe to one another, and taking the round of the *ſtomach* to return thither again, are truly a number of ſmall muſcles, or bundles of fibres, placed at ſmall diſtances from one another, no one of which ever reaches perfectly round the *ſtomach:* from theſe ſeveral ſmaller fibres are propagated in an irregular manner, which fill up the interſtices of the circular directions of theſe, and form a ſort of net-like plexus, between the fibres of which the nervous membrane of the *ſtomach* is eaſily ſeen. Theſe interſtices, in general, are of a ſort of lozenge ſhape, and the whole of theſe fibres may be ſaid to conſtitute a ſort of muſcular net, enveloping the whole *ſtomach.* All thoſe bundles of fibres, or ſmall muſcles, which are ſituated below the upper orifice of the *ſtomach*, or near about it, form together a plan, or ſeries, which runs in a ſtrait line from the upper to the lower extremity of the *ſtomach*; whereas, on the contrary, thoſe which are placed about the middle of the *ſtomach* ſeem to turn about, and form parts of circles, the convex part of all which ſtands toward the bottom of the *ſtomach:* and finally, thoſe which are placed about the neck of the *ſtomach* are much bent, and their bending is always the greater, as they approach nearer to the pylorus. This appears to be the true figure and arrangement of the fibres of the *ſtomach*; and as this is very different in many particulars, from the common accounts of anatomical authors, it was neceſſary to give this at large, in order to underſtand and explain the action of this part in the

the great work of digestion; and according to this account, the offices of every part will be very easily understood.

The circular bands of muscular fibres, placed round the orifice of the œsophagus, are designed to prevent the upper orifice of the *stomach* from being too much distended, whether by our carelessly swallowing too large morsels, or by the action of vomiting. The use of the muscular circles, at the bottom of the *stomach*, is as easily seen: the aliments received into this part of the *stomach*, were it not for these circular arrangements of fibres, would remain there, and have no tendency given them to go out of the *stomach*; but by this wonderful structure, the whole bottom of the *stomach* can at once be put into a safe and easy, though a powerful contraction, by means of which the aliments are naturally sent toward the pylorus for their discharge. These circles give the first principle of the peristaltic motion of the *stomach*, which is much the same with that of the intestines.

When the aliments have been thrown off from these circles, they are not immediately, however, discharged into the pylorus, but are thrown upon those bundles of fibres, or small muscles, which make what has been before called the *reticular coat of the stomach*. That part of this coat which immediately receives them, is that composed of segments of circles, the convex parts of which are all placed toward the bottom of the *stomach*; and as these afterwards form their contractions, their middle naturally elevates, and throws off the aliment still toward the pylorus, and this is done with the more force, as the action of these fibres is strengthened by the longitudinal ones; and, in fine, those longitudinal fibres, which are attached to the bands that surround the pylorus, when they act, contract, or pull the other parts of the *stomach* toward their insertions; so that every thing tends to help the throwing the food upon the pylorus.

The reticular coat of the *stomach* has also other great advantages; it is easily capable of extension, and consequently gives the *stomach* a capacity of enlarging, so as to hold a larger quantity of aliments than it otherwise could; and when they act, so as to be approaching toward their natural state again after such distention, this action, which is no other than their contraction, necessarily throws the aliments toward the pylorus: this contraction is always succeeded by a small dilatation again, and that by another contraction, and these alternately succeeding one another, so long as any of the aliments continue in the *stomach*, constitute what authors call its peristaltic motion. Although this motion is very slight, and only a kind of vermicular undulation, which is scarce sensible, yet there have not been wanting very great men, who have thought it sufficient for the great work of digestion. These authors set aside the use of any liquors, or juices of the *stomach*, mixing themselves with the aliments, and give the whole to this motion, which they call a kind of trituration, which they say breaks the aliments into small and fine parts, by rubbing them against one another, and that these fine broken particles make what is called chyle; but it is scarce consonant to reason, that so weak a cause should be productive of such great effects.

This motion is no stronger than the peristaltic motion of the intestines, and that is never supposed to have any such effects on their contents, but only to push them forward. The liquor prepared from the food is known also to be grey at its passing out of the *stomach*, and only to acquire its white colour in the duodenum; and how is this accountable for on the plan of trituration only? And finally, if that were all that was required to digestion, to what purpose did nature, which does nothing in vain, ordain such an abundance of fluids to be present in all places, where the aliments were destined to undergo any change? To know the abundant quantity of these, we need only follow the course of the food from the time of its being taken into the mouth to that of its being changed into chyle.

All the time that the teeth are chewing the food, the parotid glands afford a prodigious quantity of saliva, which runs into the mouth, mixes with it, and passes with it into the *stomach*; beside these, also, there are many other sources of the saliva, which all discharge it at the same time, but the quantity from these alone is not easily conceived. A soldier had, by a wound in the cheek, one of the parotids cut in two, and had the wound closed within, but not without; it was observed, that whenever he used his jaws in chewing, this one wounded gland alone discharged a quantity of lymph enough to wet several napkins; what then must be the quantity at every meal discharged from both, and from all the other sources together? Though this is all carried down into the *stomach*, yet there fresh juices are added to it. Wepfer discovered multitudes of glands in the human *stomach*, the orifices of which were very sensible; and beside these, Mr. Ruysch discovered several other eminences, which, by their resemblance to those in the second *stomach* of an ox, seem to be only cases enclosing clusters of minute glands, all destined, with the others, to pour out their contents on the mass of aliments. All these fluids, however, only change the food into a thick greyish liquor, which is too coarse to be received into the lacteals, and needs a farther elaboration. This elaboration changes it into a white liquor, which we call chyle; and this is only performed in the duodenum, where there can be no trituration, but where there is a very remarkable assemblage of different liquors to effect it: for beside the common ones, the liver and gall-bladder discharge into this intestine a great quantity of bile by the ductus choledocus; and the pancreas sends thither also a great deal of its lympth. Brunderus has observed also, in this intestine, a vast number of glands, which, according to him, make a sort of second pancreas: these all furnish, also, a great quantity of liquors to the duodenum, where this great change is made in the matter of the aliment; and it is very natural to conclude from the whole, that it is by means of these liquors that this change is effected; and if it appear, that the last change of the greyish liquor of the *stomach* into chyle be wrought by these fluids, why should it be doubted but that nature, which is alike in all its works, has used the same means in the first change, and by the liquors, mixt with the aliments in the *stomach*, has wrought them into that grey liquor they are found there changed into? Trituration does not at all seem the business of the *stomach*, nature we see has appointed another part, the mouth, for that office, and has furnished that with hard bodies, capable of tearing and grinding things to pieces. The most natural opinion, on the whole, seems therefore, that the office of the mouth was thus to rend and tear in pieces the aliments before their passage into the *stomach*, that there the juices might act more strongly upon them; in the same manner as the chemist beats and breaks to pieces the substances, which he is going to throw into proper liquors, to extract their tincture. Mem. Acad. Par. 1719.

The digestive power of the *stomach* of some fowls is vastly greater than that in men, or any other animals. Crystal bullets, some hollow, and others solid, have been crammed down the throats of hens, and have been found afterwards strangely eroded, and eaten by the juices there. Hollow bullets of glass have been also crammed down by the members of the Florentine Academy, and have been found afterwards not only eroded on their surface, but filled within with a whitish liquor like cream, which seemed to prey upon their substance. It is probable hence, that the strong digestion of these fowls may be in some measure owing to a powerful menstruum in their *stomach*; glass and crystal are two things wholly indissoluble by any menstruums we are acquainted with, and yet they are corroded here.

This menstruum in the *stomach* of these animals, assisted by what the gravel-stones, which they swallow, are able to do in the manner of teeth, may very well destroy, and reduce substances of such dense texture, as we scarce know how to manage. The glass drops with long tails, called *Prince Rupert's drops*, having been in the same manner forced down the throats of capons, were found entire in the *stomach* after many days, and burst as usual on breaking off the tail. These lost somewhat of their weight by remaining in the *stomach* some time, but the same sort of drops, when untempered by heating in the fire, lost a great deal in a very short time. One of them, with which Redi made his experiments, lost four grains of its weight in four days, and giving it to another fowl, it, in six days time, lost nine grains more. This is an argument, not only of the vast power of digestion in the *stomach* of these fowls, but of the great difference of hardness there is between the same glass when tempered, by being dropped hot into water, and when untempered again by fire.

Experiments were also made, by giving diamonds, topazes, leaden bullets, jaspers, and porphyry, to the same animals, and others of like kinds. The diamond lost nothing of its weight; the topaz almost nothing, the loss being scarce discernible with nice scales; other stones scarce lost any thing, but the leaden bullets lost considerably. Hence it is easy to conclude, that the small gravel-stones, which they pick up to serve for grinding the food in their *stomachs*, do their office without parting with almost any thing from themselves; these little stones, though less beautiful, yet approaching in their nature to the gems. There is great difference, however, between these and pearls; for it was found that four pearls given to a pigeon lost one third of their weight in twenty four hours, and eight small pearls given to another pigeon lost two thirds of their weight in two days. *Redi*, Esperienz.

STOMACH *of fishes*. The *stomach of fishes* is very different in the various kinds, in respect of size, thickness, and its several properties and qualities; but its situation is generally longitudinal, and it is single in all the known fishes, except in the *stromateus* of Rondeletius, in which it is said to be double.

The *stomach* in living fish is cold to the touch, but this is only a proof that it is less hot than our own flesh. That there is heat in it, is evident enough from the digestion which is so powerful in it, the *stomachs* of many fish digesting substances which ours could not at all effect; such are the shells of shell-fish. It is not easy to suppose this could be performed without some degree of heat in the part, but at the same time we are informed by this how small a degree

degree of heat is neceſſary for working theſe effects, and how much may be done by the continual attrition of the fibres, and by a proper fluid. *Artedi*, Ichthyolog.

STOMACH *of flies*. In examining with care the bodies of theſe little animals one may perceive, that when the paſſage of the aliments is got beyond the lungs, and below the place where they form a ſort of diaphragm, one finds the canal, that ſerved for this paſſage, forming a large, though ſhort body, the diameter of which three or four times exceeds that of the canal itſelf. This body is compoſed of three fleſhy lobes, and is unqueſtionably the *ſtomach* of the animal. The inteſtine goes out of it, very nearly from the ſame part where the other paſſage is admitted into it; the inteſtine then directs itſelf toward the anus, and afterwards runs upward again toward the diaphragm, or bottom of the lungs; and thence, after many convolutions, many times running backward and forward, it terminates in the anus.

In caterpillars and butterflies, the canal from the mouth to the anus is only one ſtrait inteſtine, but it is much otherwiſe in theſe creatures, the inteſtines, both in the fly, and in the worm it is produced from, always making a number of contortions and convolutions.

STOMACH-*bruſh*. See EXCUTIA *ventriculi*.

STOMACHICA *febris*, the *ſtomachic fever*, a name given by Heiſter, and ſome others, to a ſpecies of fever, called by others a *meſenteric fever*, and by our Sydenham *nova febris* in a peculiar treatiſe. See INTESTINAL *fever*.

STOMATICA, a term uſed by ſome for all medicines uſed in diſorders of the mouth.

STONE (*Cycl.*)—Some look upon *ſtones* as unorganized vegetables, and that they grow by the accretion of ſalts, which often ſhoot into angular and regular figures. This, it is ſaid, appears in the formation of cryſtals on the Alps; and that *ſtones* are formed by the ſimple attraction and accretion of ſalts, appears by the tartar on the inſide of a claret veſſel, and eſpecially by the formation of a *ſtone* in the human body. Dr. *Berkeley*, Biſhop of Cloyne, in Philoſ. Tranſ. N° 481. p. 326.

Stones are often corroded, and conſumed by the air. Ibid.

Naturaliſts vulgarly define *ſtone* a foſſil incapable of fuſion, yet *ſtone* has been known to be melted, and when cold to become *ſtone* again, Philoſ. Tranſ. N° 481. p. 327. See the article SCIARRI.

Hence it ſhould ſeem not impoſſible for *ſtone* to be caſt, or run into the ſhape of columns, vaſes, ſtatues, or relievos; which experiment may perhaps, ſome time or other, be attempted by the curious, who following where nature has ſhewn the way, may poſſibly, by the aid of certain ſalts and minerals, arrive at a method for melting and running *ſtone*, both to their own profit, and that of the public. Phil. Tranſ. N° cit. p. 328.

Formed STONES, among naturaliſts, mineral, or *ſtony* matter, caſt in the cavities of certain ſea-ſhells, or other parts of marine animals.

Of theſe ſome are found quite naked and bare; others have the remainder of the ſhell about them: and among theſe there are alſo found many real ſhells, ſcarce at all altered from their recent ſtate, buried at great depths in the earth, far from ſeas, and even on the tops of mountains.

This is by moſt ſuppoſed an effect of the general deluge, and by many is thought a convincing proof of the truth of that hiſtory; but there have been many who have aſſerted, that theſe bodies can convey no ſuch proof, ſince, as they affirm, they are not, nor ever were marine bodies, or owed their form to ſuch, but mere *luſus naturæ*, *ſtones* formed in the places where they are found, having no relation to animals of any kind, but only accidentally reſembling them. But the aſſertors of the former opinion have plainly the better ſide of the argument. See MARINE *remains*.

It ſeems indeed contrary to the great wiſdom of nature, which is found, in all its works and productions, to deſign every thing to ſome determinate end; that theſe bodies ſhould have been ſo nicely formed by a mere plaſtic virtue in the earth, or endued with all the characters and neceſſary parts of animal coverings, &c. for no other end but merely to exhibit ſuch a form, without having any relation to the uſes theſe particulars are appropriated to in the animal. See the article FIGURED *ſtones*.

But if the origin of the *ſtones*, found in the ſhape of ſhells, be doubtful, yet the real ſhells, found in the earth, ſurely cannot be ſuppoſed to have been formed there; yet theſe are found at as great diſtances from the ſea, and that not only in the lower grounds and hillocks, but in the higheſt parts of the loftieſt mountains, and that without the leaſt particle of *ſtony* matter about them; mere ſhells, unpetrified, and uncorrupted, and of the exact figure, ſtructure, and conſiſtence with the ſea-ſhells, which are now living, of the ſame ſpecies.

Mentzel ſays that the mount near Bologna, where the Bononian *ſtone* is found, abounds with theſe *formed ſtones*: they lie in beds with ſtrata of ſand, of a yard thick, between them, and are not lodged in *ſtone*, or any cementitious matter, as we often find them in England, but are all looſe and ſeparate: and Fabius Columna tells us, that the hills about Andria, in Apulia, abound with ſea-ſhells not at all petrified, but whole and uncorrupt; and ſeeming to have undergone no change. The mountains about Genoa have alſo been found full of them; and we have in our own kingdom numerous inſtances of them in all their ſtates, ſome ſeeming mere *ſtone*, and others perfect and unaltered ſhells; ſome looſe, and others bedded in marble, in *ſtone*, or in indurated earth.

That nature ſhould form real ſhells, without ever intending them for the covering of an animal, ſeems no way probable; and indeed, were it true, would give great ſtrength to the atheiſt's opinion, that all things exiſted by mere chance, and were intended for no end or uſe. Nor are the ſhells the only inſtances of theſe foſſile bodies perfectly reſembling animal ones, but we find with them other parts of animals, as the teeth of fiſhes and land animals; which, though met with buried in earth, or on the tops of mountains, are plainly the ſame with the ſubſtances produced by the fiſhes; &c. Of this kind are the teeth of the ſeveral ſpecies of ſharks, called *gloſſopetræ*; thoſe of the wolf-fiſh, called *bufonitæ*; the vertebræ of ſeveral fiſh, and the like.

The very inſpection is abundantly ſufficient to prove, that theſe were once parts of animals; but were that inſufficient, they have not, even in this their foſſile ſtate, ſo far diveſted themſelves of their animal nature, but that they carry proofs of it; and Columna has evidently proved their true origin from theſe. He obſerves, that all animal and vegetable ſubſtances, whether of a woody, bony, or fleſhy nature, by burning, are changed firſt into a coal, before they go into a calx or aſhes; whereas *ſtony* ſubſtances, on the contrary, do not burn into a coal, but are reduced at once into their calx or lime, or elſe into glaſs. But theſe teeth, ſuppoſed by ſome mere productions of the earth, all burn firſt to a coal, while the *ſtony* matter adhering to them does not; whence alone it is ſufficiently plain, that they and that ſubſtance are of very different kinds, and that they are truly of a bony, not a *ſtony* matter. It is alſo repugnant to that great maxim, that nature does nothing in vain, to ſuppoſe theſe teeth formed in the earth where they are now found, ſince they could there have no uſe as teeth, nor the vertebræ, or other bones, as bones. It is very certain, that nature never made teeth without a jaw, nor ſhells without an animal inhabitant, nor bones without the reſt of the body they belong to; theſe things are not made in this ſeparate and uſeleſs ſtate in the element to which they naturally belong, much leſs in a foreign one.

Their very ſubſtance and place alſo evince plainly, that they were not formed where they are now depoſited; for they are uſually lodged in *ſtone*, and *ſtones* contain not the matter of which they are made; and as to their place, they muſt be ſuppoſed to have been lodged there either when formed, which proves our aſſertion, or elſe they muſt have been at ſome time either generated all of a ſudden there, or have grown from a ſmall origin, encreaſing by little and little, as the animal ſubſtances which they imitate do. Now if the *ſtone*, in which they lie, was formed before them, and they were formed all of a ſudden in it, how came the cavity there juſt correſponding to their ſize? and if they grew by little and little, how could they force a cavity in the *ſtone*, without hurſting or cracking it?

Things that grow, expanding themſelves leiſurely and ſlowly, may indeed by degrees lift up great weights, and dilate the chinks or cracks of *ſtones*; but then they are ſubject to various contortions and alterations in their ſhape, as we daily ſee in the roots of trees, which make their way through the cracks of *ſtones*, and in common plants, whoſe roots meet with hard matter in their way, receding from the form they would have in a looſe open ſoil, and conforming to that of the body that ſtands in their way: thus, if foſſile ſhells and teeth were generated, and grew in *ſtone*, they muſt be liable to contortions and alterations in their ſhape and figure, from the ſhape of the cavities they found, or the hardneſs of the different matter they meet with in their progreſs; but nothing of this kind appears, and it is plain they were generated elſewhere, and then buried in the ſtrata of our fields, becauſe they are all of the ſame exact and regular ſhape, whether found looſe on the ploughed lands, buried in clay or marl, or lodged in beds of marble, or hard *ſtone*. All of the ſame ſpecies are, in theſe ſeveral matrixes, of the ſame exact form; whence it evidently appears, not only that they were not produced where they are now found, but even that the ſtrata were not hardened at the time when they received them.

It is alſo no ſmall proof of theſe teeth being of marine or animal origin; that they are not regularly ſhaped at the baſe, but are all broken, and that in various manners; which proves very plainly, that there has been no vegetation in the caſe, becauſe in all other figured foſſils it is obſerved, that they are never found mutilous, or imperfect. It cannot, with any ſhew of reaſon, be ſuppoſed, that theſe teeth were thus broken within the body of the *ſtone* where they now lie, but is plain that they were lodged in the *ſtone* at a time when it was ſoft, and were before that broken off from the jaw of the creature in this irregular manner.

It is likewife no weak argument, that thefe bodies are not formed at this time in the *ftone*, that they are all found perfectly alike; for were they continually encreafing, either in fize or number, it is probable that the new-formed ones would be fome way different from thofe which were of older date; nor can any thing be more abfurd, than to think that were they mere *ftones*, they would have been formed as we fee they are, not only with the external fhape and appearance, but with the whole inner ftructure of teeth; thefe foffile teeth being not like *ftones*, one homogeneous body, but compounded of various parts of a different conftitution, there muft, in the formation of it, have been made a various election of humors; one for the root, another for the inner part, and a third for the enamel, or fuperficial coat. The variety of fpecies in the gloffopetræ alone may evince, that they have belonged to the animal we attribute them to, fince they are of extremely different kinds; fome being ftrait, fome crooked, fome bent inwards, fome outwards, fome to one, and others to the other fide, fome plain, others ferrated at their edges, others undulated, and others befet all about with fmaller teeth, and fome ftrait and flatted, or cylindrical, others triangular, fome plain, and others tricufpidate, or having a fmall point on each fide the great one, or main body of the tooth; and all thefe varieties, and no more than thefe, are found in the teeth of fharks of various kinds, and at various ages, and in the different parts of the mouth. The firft row of teeth in thefe animals hanging out of the mouth, bend forward and downward, the fecond row are ftrait, efpecially towards the fides of the mouth, where they are triangular and broad, and the other rows bend downward toward the inner part of the mouth. *Columna*, de Gloffopetra.

If the *formed ftones* be original productions of nature, merely refembling thefe marine bodies in form, why are we to fuppofe that nature ftopt here, or confined her formations of this fort merely to the refemblance of fifhes, and parts of them? why might not other natural bodies as well be imitated, and *formed ftones* found in the fhape of the horns and hoofs of animals? for if we deny them their origin from animals, is it yet explained how, or in what manner they are formed? They cannot fhoot in the manner of falts, fince then the feveral fpecies, which are of the fame fubftance, ought to be alfo of the fame fhape, which is not found to be the cafe; but, on the contrary, we meet with the fame fpecies of fhell in feveral kinds of matter, and compofed of every various fpecies of *ftone*; nay, and of the pyrites, a falino-fulphureous matter, wholly different from common *ftone*, and which could not, by any principle in nature, be made to fhoot as a falt into the fame form with fo different a fubftance as limeftone; whereas, if, as we obferve, thefe bodies are really formed from fhells, &c. they muft retain the forms of thofe bodies, of whatever foffile matter they be compofed; neither could it be fuppofed, that if a falt fhould fhoot into the figure of a fhell, it fhould alfo fhoot into all the natural differences of the upper and under valve in bivalves, the one hollow, the other flat, as is neceffary in many fpecies, for the prefervation and well-being of the animal; and as thefe foffile bodies are found wholly correfponding to the moft minute particulars of the recent fhells of the fame fpecies, there feems no reafon to doubt their having been actually formed from them.

The perfection of the figures of thefe bodies is a farther proof of their origin from animals which they reprefent, fince in all cryftallizations there are many imperfect and mutilated figures, nay more than perfect ones. The hexaedral figure of common cryftal, the cubes of marcafites, and the cryftals of falts in chemical operations, are all much more regular and ordinate in themfelves, than the figures of fcallops, cockles, and other fea-fhells; yet in thefe fimple bodies we find great defects and imperfections; often the top is cut off, and fometimes one of the folid angles; and not unfrequently numbers of thefe concretions are found adhering one to another, and injuring one another's form: fometimes, alfo, their planes greatly differ from one another in fize and fituation, and often they differ, or recede other ways, from their natural and perfect figure. Since this is the cafe in the cryftallizations of bodies of fo fimple a figure as cubes and columns, terminated by pyramids, how much greater muft have naturally been the varieties and imperfections, in fuch varioufly figured bodies as the *formed ftones*, which refemble the fhells of fea-fifhes, had they been formed like thefe by mere cryftallization? but no fuch defects or irregularities appear in thefe.

As there are, therefore, none of thofe defects in thefe compound bodies, to which other much more fimple ones are found fubject, and that there are no irregularities obferved in them, the like of which are not alfo found in the living animals which they reprefent; and as in whatever country they are found, and in whatever matter they are lodged, and whatever fubftance they are compofed of, they are ever found alike among themfelves, and perfectly refembling the parts of animals, it is not to be conceived that they fhould have fhot into thefe forms merely in the manner of falts, but evident that they were parts of animals; the fimilitude of conformation in their pores, their ftriæ, hinges, teeth, prominences, &c. neceffarily inferring a fimilitude of original, and being a ftrong argument of the government of fome principle fuperior to matter figured and moved in their formations. Nor is it any fmall argument againft their arifing from the fhooting of falts, that in all the experiments made with the different falts and minerals by chemiftry, no one fimilar cryftallization, no refemblance indeed, even to the meaneft of them, was ever produced. *Steno*, de Solido intra Solidum.

To all this it may alfo be added, as an unanfwerable proof of the foffile fhells having been once marine, and having lived in the fea, that they are found with injuries which could have been no way elfe received. The purpura, and fome other fhell-fifhes, have bony tongues, with which they bore regular holes through the fhells of fhell-fifh of other kinds, in order to make their way in, and prey upon their flefh. Thefe holes are always eafily known by their regularity and fhape; and fhells bored through in this manner are not only frequent on our fhores, but there are fuch alfo found foffile, bedded in the ftrata of earth or *ftone*; and furely, if falts could be allowed to have fhot into the figures of fea-fhells, they could never be fuppofed able to fhoot into the figures of fuch wounds, as a few of thofe fhells have received in their recent ftate from other animals.

The general opinion is, that the deluge brought all thefe fhells into the places where we fee them; but this feems not eafily conceived; and as there is no argument fo good, but that being carried too far it will make againft its purpofe, fo the laying too much to the effects of the general deluge, has made many believe it has done nothing at all.

Thefe *formed ftones* and real fhells are both found in vaft ftrata on the tops of the higheft mountains, the Alps, Apennines, and others in different parts of the world. The deluge lafted only ten months, and probably the tops of mountains were not covered half that time; and thefe immenfe quantities of fhells cannot be fuppofed either to have bred there in that time, or to have been carried fo high in fuch prodigious numbers. It is more probable that thefe tops of mountains were once not fuch, but bottoms of the fea. The hiftory of the marine bodies they contain is then very plain, and earthquakes may have raifed them, or they may indeed not be fo high above the level of the fea, as we at firft fight fuppofe. If indeed we ftick to the letter of the text, in the fcripture hiftory of the creation, we can find no account for thefe bodies from that time; for if the creation of fifhes fucceeded the feparation of the land from the water in all parts of the globe, they could not be then depofited there; but it is poffible, that at the creation the whole earth was not all at once uncovered, but only thofe parts where Adam and the animals were created, and the reft gradually afterwards, perhaps not in many years, as there feems no neceffity of underftanding the account of the creation to have been in fix natural days. If we may thus underftand, and conjecture in this refpect, it is not difficult to conceive, that during the years in which the earth remained covered with fea-water, fhell-fifh might breed and multiply abundantly all over its bottom; and this bottom being afterwards elevated, deferted by the fea, and made dry land, thefe fhells muft be elevated with it, and retained in thofe ftrata, which afterwards hardened into the various kinds of earth and *ftone*: and fomething of this kind feems to have been the cafe, much rather than, according to Dr. Woodward, that all *ftony* matter fhould have been diffolved by the deluge, and afterwards have concreted again. *Ray's* Phyficotheological Difcourfes.

Solution and colours of STONES. The various beauties of the form and colour of the feveral more precious *ftones*, cannot but have been always the admiration of the curious part of the world, and the wits of the ableft chemifts have been tried, in attempting to counterfeit them; and much may be gathered even from their attempts, which have not fucceeded, toward the learning the true nature and hiftory of thefe beautiful bodies.

The beautiful figures of the Florentine marble, whofe veins reprefent trees, rivers, and ruins of buildings, are well known; as are alfo the delineations of trees and fhrubs in thofe fpecies of white agates, called *Mocoa ftones*. All the *ftones* of this kind are natural, for art has not yet been able to come up to any counterfeit of them; but it is not fo in regard to thofe agates which reprefent regular figures of beafts, &c. thefe are all affifted by art, and that by a very fimple and eafy procefs; and Mr. Du Fay, in the Memoirs of the Paris Academy, has given at one view the feveral ways, then known, to penetrate into the fubftance of agate, marble, &c. and to lodge figures in them.

The *ftones* fubject to be tinged he divides into two claffes, the harder and the fofter. Of the harder kind are thofe which refift the force of acids, even of the moft powerful kind; and of this clafs are agates, onyxes, and all that are vulgarly comprehended under the general name of the gems, or precious *ftones*, with cryftal, porphyry, granite. Thefe, and the like *ftones*, are not foluble in any of the known acids, yet thefe fame acids, impregnated with the folutions

of metals, are capable of penetrating very deeply into them, and tinging them with different colours. The simple agates and jaspers, and other *stones* of the like uniform structure, are easily coloured in an uniform manner; but those which are variegated with veins are composed of several different sorts of matter, and therefore are less easily, and less evenly stained. As the tinging matter does not penetrate the several beds, or veins, in the same manner, therefore all that can be done to these, is to add spots and veins to their natural ones, but they cannot be tinged throughout to one uniform colour, as the chalcedony, or white agate may.

If a small quantity of a solution of silver, in spirit of nitre, be poured upon one of these agates, and the *stone* exposed to the sun, it will in a few hours be tinged to a reddish brown colour; and if more of the same solution be added, and it be again exposed, the colour will become stronger, and will penetrate deeper into the body of the *stone*; and if the *stone* be not too thick, and the solution be rubbed on both sides, it will tinge it throughout. Nor is this all the effect, for it will give it several veins and lineations, which were not distinguishable in it before; the reason of which is, that in all these *stones* there are some parts harder than the rest, and consequently more difficultly coloured, and these remaining, therefore, paler than the rest of the mass, make the lines and veins in it.

If there be added to the solution of silver, used for this purpose, a fourth part of its quantity of soot, and as much salt of tartar, the colour becomes grey; and if, instead of this soot and tartar, the same quantity of plumose alum be used, the *stone* will be tinged to a deep violet colour, tending to black.

A solution of gold gives agate only a pale brown colour, and that penetrates but a little way into it; and a solution of bismuth gives a colour, which appears white when the light falls directly upon it, but brown when it is held against the sunshine, or a candle; and all the metallic and mineral solutions, employed in the same manner, affect the *stone* more or less in the same way.

The exposing the *stones* to the sun is a very necessary article in the process, since without that the tinge is but very faint, and penetrates but to a very little depth. To trace in the chalcedony, or white agate, figures of any determinate kind, the usual method is this: before the agate is polished, mark out the intended figure with the point of a fine needle, and afterwards with a brush, or a pen, follow those lines with a very strong solution of silver. One would imagine that the dendritæ, or delineations of trees in Mocoa *stones*, might be imitated in this manner; but it is difficult to give the due blackness of colour, and to mark the figures with a like precision and exactness. If any *stone* should, however, be suspected to be adulterated, or counterfeited in this manner, it is easily brought to the trial; for if it be thus made, a small heat over the fire will almost entirely divest it of its colour, and the rubbing a little spirit of nitre, or aqua fortis over it, will have the same effect. In both cases the *stone* may, however, be restored again to its beauty; in the first, by tinging it afresh with the same liquor, and in the last, by only exposing it for several days to the sun.

It is well known, that by means of fire alone the amethyst, the sapphire, and the other gems, may also be wholly divested of their beautiful colours. The method of doing this, is, to put the gems into a crucible, surrounding them with sand, or with steel filings; then putting them into the fire, they lose their colour as they become hot, and are taken out wholly colourless. If the white agate be calcined in this manner alone, it becomes of a cloudy or opake white; but if it has before been stained with the solution of silver, those spots or stains become of a yellow colour, which aqua fortis afterwards has no power to take away. If the agate be calcined first, and afterwards rubbed over with the solution of silver, it receives some spots and lines of brown. The cornelian loses a great part of its redness by calcination, and becomes of a dusky flesh-coloured white; and the Mocoa *stone*, treated in the same manner, loses all its colour, and the delineations of trees disappear.

There are many *stones* on which the solution of silver has no effect; of this number are all the gems, rock crystal, and the like. The dendrites of Catalonia is also of this kind; and of this *stone* the artificers relate an odd phænomenon, which is, that if it be sawn asunder there are very few delineations observed in it, but if it be split by a blow, it is usually found full of them. The reason of this is only that these delineations are so many flaws and cracks, and the *stone* breaks easiest in these places.

The effects of the solution of silver are different, as to degree of colour, on different *stones*. The Oriental agate receives from it a deeper and blacker tinge than the common chalcedony. Some agates, naturally distinguished by their yellow spots, receive a purple colour from it. The jade *stone*, used by the Turks, takes only a faint tinge of brown. The common prime emerald, or root of the emerald, becomes blackish with it. The Oriental granite is tinged in many places with a violet colour by it; this is principally effected in the white parts. The solution does not act much on the black ones, only that it takes some of them away. The serpentine marble receives an olive colour from it; but it is remarkable that the amianthuses, and the talcs, and other foliaceous *stones*, are wholly unaffected by it.

Marble being a substance greatly softer than agate, receives the colours with much greater ease, and the doing this in an accurate manner has been the subject of the attempts of many eminent men. Kircher has given some directions for the staining marble, which have been translated word for word into the Philosophical Transactions; but they are so indeterminate and uncertain, that nothing can in reality be learned from them. Many others have written also on the same subject, but Mr. Du Fay is the only one whose experiments are plainly and clearly laid down, and may be followed by any body.

This gentleman chose the common white marble without veins for making his experiments, for the same reason that he chose the plain agates, because in the veined ones there are several different sorts of matter, all of which are not to be penetrated with equal ease. The solution of silver penetrates into marble to the depth of an inch, or more, and gives a tinge, reddish or purple, at first, and afterwards brown, from which colour it never varies afterwards. It always takes off the polish of the marble, eating away a part of its surface. The solution of gold does not penetrate so deep into marble as that of silver, but it gives a beautiful violet colour. Both these operations are much assisted by exposing the marble to the sun. The liquors usually diffuse themselves, and spread every way in the marble, so that it is not easy to make any figure with them that shall keep its outline tolerably regular.

The solution of copper gives marble a beautiful green tinge; but it does not penetrate deep, and on the application of boiling water becomes black; when the surface is polished off afterwards, however, it becomes again of a beautiful green.

Beside the powerful acid menstruums, there are many other liquors which have a power of penetrating deep into marble. Of this nature are all the oily fluids; but the expressed oils have this disadvantage, that they leave a fattiness in the marble which will not suffer it afterwards to take a good polish. All substances which can penetrate marble, can carry colours into it; but such are most eligible, which having lodged the colours evaporate, and leave them there, without injuring the *stone*. Spirit of wine is of this number; it is excellently qualified for the extracting beautiful tinctures, and sinks them very deep. Oil of turpentine also has its value, but it does not take tinges so well as the spirit. Some have recommended lixiviums of the fixt alkaline salts, but they very rarely produce any beautiful colour. In the using these fluids the marble is to be gently heated, and the spirit is by that means evaporated before it is cooled, leaving its colour always behind. White wax penetrates very deep into hot marble, and conveys colours into it in a very beautiful and determinate manner. There are however but a few bodies, which will impart their colours to wax, and therefore this valuable means is of a very limited use.

Several of the gums alone are also able to tinge marble very strongly. Dragons blood, and gamboge, if rubbed on hot marble, penetrate it to the depth of about a twelfth of an inch: the gamboge requires the marble to be hotter than the other, and tinges it to a very beautiful yellow; the dragons blood tinges to a red in different degrees, according to the heat of the marble.

If these gums have been used to polished marble, there is no farther caution necessary, than the cleaning them off from the surface with a little spirit of wine: but the way to make them sink deeper into the *stone*, is to take off the polish by rubbing the surface with pumice, or the like, and then the gums sink much farther, and the colours appear very beautiful when the marble is polished again.

Though these gums act alone, yet they will succeed much better if dissolved in spirit of wine, and applied with a pencil; for by this means they sink deeper in, and the figures traced out will keep their determinate form and outlines, these solutions fixing immediately, without spreading any way. It is also remarkable, that the solution of dragons blood hardens the marble, and renders it less soluble in acids than before; so that if a piece, stained in part with this solution, be afterwards rubbed over with an acid dissolvent, and its surface eaten away to some depth, the parts which are coloured will all stand out above the rest.

A tincture of Brasil wood in spirit of wine tinges marble red, and if the heat given to the marble be greater, it becomes purple; but both these colours fade a little in keeping. A tincture of cochineal gives a purplish red, and the more the marble is heated, the farther the colour penetrates, and the deeper it is. In oil of turpentine the colour of cochineal penetrates much deeper into the marble, but it has a brownish cast. Alkanet root, by means of spirit of wine, gives also a red colour, which, if the heat be too great, changes to brown; and this, and most other of the like matters, tinge the marble, in tincture with spirit, to a slight depth; and in oil of turpentine they sink much deeper, but then the oil leaves a greasy look upon the marble.

If verdigreafe be boiled a confiderable time in white wax, it tinges marble, when rubbed hot upon it, to a beautiful green, little inferior to that of the coarfer emeralds, and the colour fpreads itfelf very equally, and penetrates to a third of an inch deep; if the marble be made too hot, the colour becomes that of the jade *ftone*. Alkanet boiled in white wax gives a flefh colour, which penetrates very deep; and the roucou boiled in wax makes a permanent yellow, which alfo finks very deep. The beft way of heating marble for this purpofe, is to lay the piece, intended to be ftained, upon a bed of fand, a fifth of an inch deep, upon an iron plate; this is to be fet over the fire, and when of a proper degree of heat, the colour is to be applied. The juft degree can only be found by experience, and it varies indeed in almoft every colour; but in general, the finer colours require the marble to be of fuch a heat, that the hand can juft bear to be laid upon it, and the others require a fomething greater degree than this.

Black is, of all colours, the moft difficult to give in this manner to marble; and perhaps indeed it is impoffible to give that colour in any degree of perfection, and that for this plain reafon, that all thefe colours only fill the interftices between the granules of the marble, thofe granules themfelves remaining unaltered: thus, in the other colours, the whitenefs of the granules is only a heightning to the tinge, making it brighter, and a little paler; but the whitenefs can never fail to appear diftinguifhably as fuch in black, and by that means deftroy that colour.

Next to black, blue feems the moft difficult, of all the colours, to give to marble. Mr. Du Fay, however, having found by Mr. Geoffroy's experiments, that oil of thyme, by long ftanding with fpirit of fal armoniac, acquired a blue colour, tried this mixture, and found it fucceed very beautifully. But this is one of thofe colours which require the marble to have but a very fmall degree of heat, fince a greater would evaporate them before the colour had time to penetrate. The colours of the gums may be laid on when the marble is cold, and on heating it afterwards they will fink into it.

There is another very elegant fort of workmanfhip to be employed on marble, that is, the tracing figures in relief in it; and this is done much more eafily than might be imagined, there being nothing more required to it, than the faving the parts which are to be left in relief, by covering them with a varnifh, and eating away the reft by means of an acid. For this purpofe let the defigned figures be traced in chalk upon the marble, and cover them with a bed of varnifh, made by diffolving a piece of common red fealing-wax in fpirit of wine; then pour on the marble a mixture of equal parts of fpirit of falt and diftilled vinegar, and this will eat down all the ground, and leave the figures ftanding, as if engraved with immenfe trouble. The adding the colours, before defcribed, to thefe marbles afterward, in a regular manner, will give them a furprifing beauty. Mem. Acad. Par. 1728.

Electrical attraction of Stones. Many *ftones* have been obferved by Dr. Lifter to have a fort of *electrical attraction* to vegetable refins.

This author obferves, that having placed fome foffils in a cabinet made of Barbadoes cedar, and examining them at fome diftance of time, he found them all covered with a liquid refin like Venice turpentine. Many of the *ftones* were wrapt up in papers, yet thefe, as well as the reft, were covered with this refin; though, upon the moft diligent fearch, there could not be found any exfudation on any part of the cabinet. The iron ores were moft of all covered with refin, all the kinds of the hæmatites being thick coated with it; and among the aftroitæ fome were thinly covered, and others perfectly free from it.

It was not owing to the texture and denfity of the *ftones*, that they either efcaped this, or had it, but thofe of the moft open grain, and thofe of the clofeft, were indifferently covered with it. It is certain from this fingular obfervation, that the whole body of the turpentine of the cedar wood was carried up into the air, and floating in it was again condenfed, on the coming into contact with certain *ftones*, tho' not with others.

There are feveral vegetable fubftances, which in this manner emit their whole body into the air: of the number of thefe is camphor; but the *ftone*, that will again condenfate this into camphor, is not known. Philofoph. Tranfact. N° 110.

Formation of Stones. See Lithogenesia.

Medical Stones, a term ufed by fome to exprefs thofe particular *ftones*, which for their real or imaginary virtues have, at one time or other, been made ingredients in medicinal preparations.

The opinions of the antients, in regard to the virtues of gems and precious *ftones*, were very whimfical; they fuppofed that they had certain fympathetic properties, and that the wearing them on the finger, or carrying them in the pocket, would cure difeafes, render the Gods propitious to their prayers, or fave them from thunder. Thefe have been defervedly laughed out of the world in our more enlightened times; but it has remained a queftion, and does fo even to this time, whether or not fome of the gems have real medical virtues, naturally refulting from their parts, and conftituent matter. It appears from the prefent ftate of the gems, that they were once fluid bodies, or, at leaft, made up in part of fuch fubftances as were once fluid; and as in this ftate they were capable of receiving metalline admixtures, it is poffible they may derive certain virtues from thofe admixtures; and fome concurrent circumftances in that mixture may have exalted the virtues of the bodies received, beyond what they could naturally and fingly have excited.

The diaphaneiety, the external figure, and the internal ftructure of gems, all argue ftrongly for their having once been in a fluid ftate; and their colours, which feem to be evidently adventitious, and imparted either by fome coloured mineral juice, or fome tinged exhalation, could have fo deeply affected the denfe texture of thefe *ftones*, as to pafs through all their parts in no other manner, than when that *ftone* was in *folutis principiis*, or in a fluid ftate.

There are fometimes found extraneous matters lodged in the bodies of the gems themfelves, which could only have been enveloped in them in this manner while they were foft; and even in moft of them, the art of the chemift is able to difcover real particles of metals, which muft have been mixed in their fubftance at fuch a time, and to which they may very probably be indebted for real virtues.

Rubies, when too fmall to be of value as gems, are in fome places, where they make a fort of fand in the rivers, worked to fome advantage as ores of gold. The amethyft evidently contains iron, and the emerald copper; why fhould it then be fuppofed impoffible, that the virtues of thefe metals may be found in the gems which contain themfelves, and that in fo pure and fine a ftate, as no chemical procefs can afford them in? The weight of many of the coloured gems is much greater than could be expected in *ftones* of that hardnefs and confiftence, and is plainly owing to the admixtures of the metalline particles of the various forts they contain.

Mr. Boyle's opinion of the origin of the real virtues of the gems, is, that while the petrefcent matter was yet in a fluid ftate, the mineral matter was received into, and intimately mixed with it, fo as that the whole became but one *ftone*; and that the virtues are always fuch, as may be derived from the impregnating metal or mineral, and are various in degree, according to the various ftates of the metal, and its quantity received into the compofition.

If this fyftem holds good as to the gems, it will be much more naturally applicable to the femipellucid *ftones*; many of which have gravities fo great, as plainly to denote the metalline or mineral matter that makes a part of them. The metalline fubftances, that may be feparated out of thefe *ftones*, give great proof of the truth of this fyftem: thus the hæmatites contain a very large quantity of iron, and the lapis lazuli, and turquoife *ftone*, contain very large quantities of copper; and many of the jafpers hold no inconfiderable portion of the fame metal. *Boyle* of the Origin and Virtues of Gems.

Stone *for building*. Care muft be taken to dig *ftone* at the proper feafon; for that *ftone* which, taken out of the quarry at one time, would foon moulder away, will at another feafon endure the weather for many years, if not ages. *Boyle*'s Works Abr. Vol. I. p. 111.

Stone, in commerce. The *ftone troy*, in Scotland, contains fixteen pounds, the pound being two marks, or fixteen ounces. Tr. Pract. Geom. p. 153. See Pound.

Stone-*brafh*, in agriculture, is a light lean foil, full of larger and fmaller maffes of rubble *ftones*.

Thefe are to be tilled according to the condition in which they are found, for if they are graffy they fallow them pretty late; but if they have no grafs upon them, they fold them in winter, when the fheep's dung, with the help of fome hay-feed, will furnifh them with grafs: or elfe, early in the fpring they lay upon them old thatch or ftraw, or the ftrawy part of old dunghills, earth out of ditches, or the like, which will all, more or lefs, help forward a coat of grafs upon the land; for it is a rule in regard to thefe lands, that they muft have a covering of grafs before they are fallowed, elfe they will yield but a poor crop. *Plot*'s Oxfordfhire, p. 247. See Stony *land*, infra.

STONE-*chatter*, in zoology, the name of a ſmall bird of the *œnanthe*, or fallow-finch kind, called by ſome authors *rubetra* and *muſcicapia*, and in ſome places the *ſtone-ſmich*, and the *moor-titling*.

It is about the ſize of the common linnet. Its beak is longiſh, ſtrait, and ſharp, and is black, as is alſo its mouth within. Its head is large, and in the male is black almoſt all over, as is alſo the upper part of the throat; but in the female theſe parts are variegated with black and brown. The neck is black, and marked on each ſide with a white ſpot, the two ſeen together looking ſomewhat like a white ring. The middle of its back is alſo black, but the extremities of the feathers are yellowiſh. It has a white ſpot juſt above the rump. Its breaſt is of a ſomewhat reddiſh yellow, and its belly white, with a faint caſt of red. In the female, the feathers of the back and neck are of a ſomewhat greeniſh tawny, with black middles; the upper part of the throat is grey, and the breaſt red. It is common on heaths, and makes a very loud, and often repeated noiſe. *Ray*'s Ornitholog. p. 169.

STONE-*curlew*, in zoology, the Engliſh name for the *œdicnemus*, a bird of the colour of the curlew. See the article ŒDICNEMUS.

STONE-*phoſphorus*. See LITHOPHOSPHORUS.

STONE-*plant*. See LITHOPHYTON.

STONE-*ſmich*, a common Engliſh name for that ſpecies of œnanthe, which we more frequently call the *ſtone-chatter*. See the article STONE-*chatter*.

STONE-*ſucker*, in zoology. See PETROMYZON.

STONY *land*. The farmers expreſs by this term two ſorts of land, the one full of large flints and pebbles, and the other full of fragments of free *ſtone*, or other coarſe *ſtones*.

Theſe lands in many places yield good crops, and the general rule is, that in ſtiff and cold lands the *ſtones* ſhould be as carefully picked out as may be, but in light and dry grounds they ſhould be left. In Oxfordſhire they have great quantities of a lean earth, and a ſmall rubble-*ſtone*, or a ſtower ſort of land mixed with it; this is ſometimes very full of weeds, and ſometimes very clear of them: if they are weedy they fallow them late, but if they be ſeary, as they expreſs it, that is, if they have no ſwerd upon them, they either fold them in winter, and add ſome hay-ſeed to the ſheep's dung, to bring up graſs, or elſe they lay old thatch or ſtraw, and dung upon it; for they reckon, that if theſe lands have no ſwerd upon them before they are fallowed, they will by no means be brought to bear a good crop, but a great deal of May-weed, and other unprofitable herbs. In September, November, and December, they fallow as the ſwerd directs them: if this is done in either of the two laſt months, they call it a winter-fallowing, and never ſtir it again till they plow it, and ſow it with barley; and theſe lands are reckoned to do better than if finely tilled. They will bear wheat and meſlin in a kindly year, and large crops of barley, if they are well managed, and kept in good heart.

They always fallow theſe lands every other year, unleſs they ſow peaſe upon them; ſometimes they ſow them with lentils; and when they are quite worn out, they lay them down for clover, or rey-graſs. *Mortimer*'s Huſbandry, p. 71.

STOOL (*Cycl.*)—STOOL, in mining, is uſed when the miners leave digging deeper, and work in the ends forward. The end before them is called the *ſtool*. *Houghton*'s Compl. Miner in the Explan. of the Terms.

Bloody STOOLS, in medicine. The ſpirit of vitriol, mixed with the patient's drink, has often been found beneficial in cures of *bloody ſtools*.

Retention of the firſt STOOLS, in infants. See INFANT.

STOP, in the manege, is a pauſe, or diſcontinuation of going. In order to *ſtop* a horſe, the rider ſhould, in the firſt place, bring to the calves of his legs, to animate the horſe, then bending his body backwards, raiſe the bridle-hand, without moving the elbow; then vigorouſly extend the hams, and reſt upon the ſtirrups, to make him form the times or motions of his *ſtop*, in falcading with his haunches three or four times. You ſhould not form the *ſtops* of your horſe ſhort and precipitate, leſt you ſpoil his hams and mouth. After *ſtopping*, a horſe ſhould be made to make two or three corvets.

The oppoſite term to *ſtop* is *parting*. In former times, the *ſtop* of a horſe was called *parade*. See the articles RAISE and NAILS.

Half a STOP, is a *ſtop* not finiſhed by a *peſate*; ſo that the horſe, after falcading three or four times upon the haunches, reſumes and continues his gallop, without making *peſates*, or *corvets*. See the articles PESATE, CORVET, &c.

STOP, at ſea, a word uſed by him that holds the half-minute glaſs, in heaving the log; for immediately when the glaſs is out, he calls *ſtop* to them that let run the line. See the article STOPPING.

STOPPAROLA, in zoology, the name of a bird of the lark kind, deſcribed by Aldrovandus, and ſuppoſed by Mr. Ray to be the ſame with the *ſpipoletta*, or the *tordino* of the Venetians. See the article SPIPOLETTA.

STOPPER, in a ſhip, a piece of rope having a wale-knot at one end, with a lannier ſpliced into it, and at the other end made faſt in the place where it is to be uſed. Its uſe is to ſtop the main-halliards, or the cable. The *ſtopper* for the halliards is faſtened at the main-knight, and it ſerves, when they are hoiſing the main-yard, to ſtop it, that it don't run out too faſt. They bind the wale-knot about the cable with the lanniers, and that ſtops it, ſo that it cannot ſlip away. This *ſtopper* is faſtened to the bottom of the bits by the deck. The word is, *lay on the ſtoppers*; and a ſhip is ſaid to ride by the *ſtoppers*, when the cable is faſtened, or tied only by them, and not bitted; but this is not ſafe riding in a ſtreſs of weather.

STOPPING (*Cycl.*)—STOPPING *a leak*, at ſea. See LEAK.

STOPPING *a ſhip*, at ſea. When a ſhip comes to an anchor, and the cable is veered out by degrees till the ſhip is found to ride well, and then ſtopped, it is called *ſtopping the ſhip*.

STORAX (*Cycl.*)—The writers of the middle ages have greatly perplexed the hiſtory of this drug in general.

The true ſtate of the caſe is this; all authors, of all times, have deſcribed at leaſt two kinds of *ſtorax*, a dry and a liquid kind. The Arabians and Greeks have both joined to call the dry kind *calamita*; but neither the origin of that epithet, nor its true ſignification, have been conſidered as they ought.

The *ſtorax ſicca*, or *calamita* of the Arabians, was the worſt of all the kinds of *ſtorax*; it was only the refuſe, after making the artificial liquid kind.

They ſometimes boiled the fruit of this tree, and ſometimes its bark, and out of both extracted a liquid *ſtorax*; and the remainder of both was ſaved under the name of *dry*, or *calamite ſtorax*. It is no wonder, therefore, that the *calamite ſtorax* of the Arabians was the worſt of all the kinds; and as ſuch the term is always to be underſtood, when met with in the works of the Arabians.

On the other hand, when the Greeks would expreſs the very beſt and fineſt *ſtorax*, they always do it by the term *calamite ſtorax*. The two kinds of *ſtorax* they mention, are the reddiſh and the black. The latter was foul, and much leſs in eſteem. The former was the fine pure *ſtorax*, naturally exſudating from the tree. This they ſometimes called *calamite*, becauſe in the form of pieces of reed.

The common opinion, in regard to this word, is, that it was an epithet given to the fineſt *ſtorax*, from its being put into reeds to be brought over with ſafety: but this was not the caſe. The fineſt of all *ſtorax*, was that which voluntarily exſudated from the tender twigs, and young ſhoots of the tree: this ſometimes coated over the whole twigs for an inch or two in length, and reſembled a reed, or other hollow cylindric body, drawn on over the twig. This was the origin of the name *calamite*, or reed-like *ſtorax*, given to this which was of the red *ſtorax* kind, but finer than that of the trunk or larger branches, and approaching to a yellowiſh hue.

Pliny gives even a ſtricter account of the name than this: he ſays, and that from the authority of authors of repute, that the *ſtorax*-tree being very ſweet taſted, and very ſoft in the young wood, worms were very apt to get into the ſhoots; and that when they did ſo, they would eat away all the woody matter, and leave only the bark. The *ſtorax*, extravaſated by theſe punctures, uſed to coat over theſe tubes, and they then exactly reſembled pieces of reed artificially covered with ſome gum.

According to this account, the name *calamita* was extremely appoſite to that *ſtorax*, and it had as much title to the epithet, in all appearance, as the *adarce calamites*, which always gathered about reeds, and was therefore ſometimes ſimply called *calamites*. See ADARCE.

STOREA, among the Romans, a kind of baſket made of ropes or ruſhes, for gathering flowers or garden-fruits. *Pitiſc.* Lex. Ant. in voc.

STOREA was likewiſe a kind of defence, made of large cables faſhioned into a ſort of nettings; which was ſo ſtrong, that no weapon, though thrown out of an engine, could penetrate it. See *Pitiſc.* in voc. and *Cæſ.* Bell. Civ. II. 9.

STORM-*fink*, in zoology, the name of a ſmall bird deſcribed by Hoier, and ſaid to be ſeen principally at ſea, where it is looked on as a foreteller of bad weather.

It is a little larger than the common ſparrow, and is all over of a greyiſh colour. It is very remarkable for its ſkimming very ſwiftly along the ſurface of the water. When large flocks of theſe appear, the mariners know they are to expect a *ſtorm*, and prepare for it. *Ray*'s Ornithol. p. 306.

STORYNE, the name of an inſtrument uſed by the antients for drawing blood from the noſe; but we are not perfectly informed of its ſhape or ſtructure.

STOVE (*Cycl.*)—STOVES, in gardening, are buildings erected for the preſervation of tender exotic plants, which, without that aſſiſtance, will not bear the cold of our winter, becauſe they require an artificial warmth.

Stoves are of two kinds, diſtinguiſhed by the names of the *dry*, and the *bark ſtove*.

The dry *ſtove* has the flues, in which the ſmoak is carried, either laid under the pavement of the floor, or erected in the back part of the houſe over each other, and returned ſix or eight

eight times all along the *ſtove*. In theſe *ſtoves* the plants are placed on ſcaffolds, and benches of boards, raiſed above one another; and the plants, principally preſerved in theſe, are the aloes, cereuſes, euphorbiums, tithymals, and other ſucculent plants, which are impatient of moiſture in winter, and therefore are not to be kept among trees, or herbaceous plants, which perſpire freely.

The bark *ſtoves* are made with a large pit, nearly of the length of the houſe, which is three feet deep, and ſix or ſeven feet wide. This pit is to be filled with freſh tanner's bark to make a hot-bed, and in this the pots, containing the tender plants, are to be plunged.

This invention of tanner's bark for hot-beds has been of prodigious ſervice to the curious in gardening, as many plants are, by this means, annually preſerved and raiſed, which no other method could have made endure our climate.

The dimenſions of theſe *ſtoves* muſt be wholly directed by the number of plants intended to be preſerved; and for the dry *ſtove*, the floor muſt be raiſed above the ſurface of the earth, more or leſs, according to the dryneſs or wetneſs of the ſoil. In the front there is to be a walk about twenty inches wide, for the convenience of walking. The fire-place may be made either in the middle, or at one end, and the furnace muſt be contrived according to the nature of the fuel which is to be burnt there. The beſt firing, when it can be had, is turf, for it burns longer, and more moderately, than any other fuel, as alſo more uniformly, and therefore requires leſs attendance.

The entrance into the bark *ſtove* ſhould always be either out of a green-houſe, or the dry *ſtove*, or elſe through the ſhed where the fire is made; becauſe in cold weather the front glaſſes muſt not, by any means, be opened, and the top ſhould be covered either with tarpaulins, or ſliding ſhutters, in bad weather.

The tender ſhrubs and exotic plants muſt be plunged in their pots into the bark beds; ſuch are the caſhew, cabbage-tree, cocoa-tree, dumb-cane, ſuſtick, logwood, mancinel, papaw-tree, four-ſop, and the like; and upon the top of the flues may be ſet the melon, thiſtle, the tender cereuſes, and the like.

The thermometer, by which the heat in the *ſtove* is regulated, muſt always be hung with its back to the ſun, and as far from the flues as may be. The proper ſtructure of theſe ſhelters, for the curious part of the vegetable creation, is to have a green-houſe in the middle, and two *ſtoves*, and a glaſs caſe, at each end. The particular rules for the ſtructure of all theſe, with plans of them, are accurately given by Mr. Miller in his Dictionary. *Miller's* Gardner's Dictionary.

STOWS, in mining, are ſeven pieces of wood, ſet upon the ſurface of the earth, faſtened together with pins of wood.

STOWING *the hold*. See the article HOLD.

STRAIGHT, (*Cycl.*) in geography. See the article FRETUM.

STRAIGHT, in the manege. To part, or go *ſtraight*, or right out, is to go upon a tread traced in a *ſtraight* line. When you would puſh your horſe forwards, make him part *ſtraight*, without traverſing, or bearing ſidewiſe.

STRAIGHT *membered*, called in French *droit ſur les jambes*. See the article LEG.

STRAIKS, in the military art, are ſtrong plates of iron, ſix in number, fixed with large nails, called *ſtraik-nails*, on the circumference of a cannon wheel, over the joints of the fellows, both to ſtrengthen the wheel, and to ſave the fellows from wearing on hard ways or ſtreets.

STRAKE, in the ſea phraſe, a ſeam between two planks; as the *garboard-ſtrake* is the firſt ſeam next the keel. They ſay alſo a ſhip *heels a ſtrake*; that is, hangs or inclines to one ſide the quantity of a whole plank's breadth.

STRAMONIUM, *thorn-apple*, in botany, the name of a genus of plants, the characters of which are theſe. The flower is of the infundibuliform kind, and conſiſting of one leaf, and divided into ſeveral ſegments at the edge. The piſtil ariſes from the cup, and is fixed, in the manner of a nail, to the hinder part of the flower. This afterwards becomes a fruit of a roundiſh figure, echinated in moſt of the ſpecies, and divided into four cells, containing ſeveral large ſeeds, uſually of a kidney ſhape. The ſeptum, which divides the head or fruit, is of a cruciform ſhape, and has four placentæ, to which the ſeeds adhere.

The ſpecies of *ſtramonium*, enumerated by Mr. Tournefort, are theſe. 1. The round thorny-fruited *ſtramonium* with ſingle white flowers. 2. The round thorny-fruited *ſtramonium* with double white flowers. 3. The round thorny-fruited *ſtramonium* with ſingle violet-coloured flowers. 4. The round thorny-fruited *ſtramonium* with double violet-coloured flowers. 5. The Ægyptian *ſtramonium* with double flowers, white within, and of a violet colour on the outſide. 6. The white-flowered *ſtramonium* with an oblong prickly fruit. 7. The purple-flowered *ſtramonium* with oblong prickly fruit. 8. The violet-flowered *ſtramonium* with oblong prickly fruit. 9. The ſharp long-thorned *ſtramonium*, called by authors *ſtramonium ferox*. 10. The ſmaller American *ſtramonium* with leaves like thoſe of alkekengi. 11. The ſmooth-fruited *ſtramonium* of Malabar with ſingle violet-coloured flowers. 12. The ſmooth-fruited *ſtramonium* of Malabar with double flowers. *Tourn.* Inſt. p. 118.

STRANGALIDES, a word uſed by authors to expreſs hard tumors in women's breaſts, ariſing from coagulations of obſtructed milk after child-birth.

STRANGLES, in the manege, is a collection of foul humors formed in the body of a young colt; which are voided by the noſtrils, or by a ſuppuration of ſome glands or knots, that lie between the bones of the lower jaw, and are crowded with impurities.

The *falſe ſtrangles* happen in old horſes, that have not well caſt the *ſtrangles*.

STRANGULATIO, a word uſed to expreſs that kind of ſuffocation which is common to women in hyſteric diſorders; and for the ſtraitning the inteſtines in hernias.

STRANGULATORIA, in the materia medica, a name by which Avicenna, and ſome other authors, have called the *doronicum*, or leopard's bane. *Ger.* Emac. Ind. 2.

STRANGURY (*Cycl.*)—The vulgar generally underſtand by this word the three ſeveral complaints, called by phyſicians *ſtrangury*, *dyſury*, and *iſchury*; the differences of which are theſe.

The *ſtrangury* is properly and diſtinctly a difficult excretion of urine, which comes away by drops, with a ſenſation of a ſpaſmodic pain about the ſphincter and neck of the bladder.

The *dyſury* is a difficulty of making water, attended with a violent attempt and preſſure of the parts. This ſometimes has its origin from the kidneys, ſometimes from the bladder.

The *iſchury* is a total ſuppreſſion of urine for ſome days, without the leaſt drop being voided, or the patient's feeling the leaſt ſtimulus toward attempting to void it.

Theſe three diſtemperatures of the urinary organs, though very properly diſtinguiſhed by their ſeveral names, are, however, in reality all the ſame in their origin, and differ only in degree.

In the *ſtrangury*, the difficulty of voiding the urine is ſomewhat tolerable, and is not attended with any ſenſation of heat, but rather with a coldneſs; and though the urine is voided only by drops, yet, as this is continual, there is more in quantity voided in this, than in the ſame time in a *dyſury*. The *ſtrangury* ſeems a ſort of middle complaint, combined of the two others, the *diſury* and *iſchury*; and it differs in point of duration, being ſometimes only a complaint of a few hours, and ſometimes fixing itſelf upon the patient for a long time. Sometimes alſo it is idiopathic, and is properly a diſeaſe in itſelf; but ſometimes it is ſymptomatic, attending nephritic complaints of ſeveral kinds.

Phyſicians alſo diſtinguiſh the *iſchury* into the proper, and improper: the firſt is the denomination they give to this diſeaſe, when the bladder is full of urine all the time, and is ſo diſtended, that it brings on ſpaſmodic affections, which prevent the natural efforts for the excretion of it. The improper *iſchury* is that in which there is no ſuch fullneſs of urine, but this fluid is, by ſome means, prevented from flowing as it ought into this receptacle. We muſt be careful not to confound with theſe diſtempers the natural imminution of urine, which happens after copious ſweats, or diarrhœas, in which a great quantity of wet ſtools have been voided: this is diſtinguiſhed from theſe morbid affections, by its being attended with no pain, and always going off of itſelf.

Symptoms of a STRANGURY. Theſe are of frequent irritations to make water, which are ſucceeded either by a few drops, or a ſomewhat larger quantity, according to the nature and violence of the caſe; there is always a ſenſation of coldneſs while the urine is coming away, and a heat afterwards; and the whole body is very frequently affected with ſhiverings and ſudden coldneſs.

In a *dyſury*, the difficulty of voiding the urine is great, and the pain violent; but in this caſe it does not go off as ſoon as the urine is voided, but continues afterwards.

In the *iſchury*, while there is for ſeveral days together no attempt to the voiding any urine, if the complaint is in the bladder, the patient feels a weight and preſſure upon the os pubis; but when the kidneys and ureters are in fault, the pain is felt in the loins; and ſometimes this is attended with heart-burnings, iſchiatic pains, and even with diſorders of the ſtomach, and actual vomiting; and if the cauſe is ſome inflammable tumor, which is not unfrequently the caſe, then the pains are very violent, and the body is all over preternaturally hot.

The *dyſury* more frequently attacks thoſe who are ſubject to the ſtone in the kidneys or bladder, or to other nephritic complaints, and ſuch as have taken cantharides internally, and by that means brought on an eroſion of the neck of the bladder; ſometimes, alſo, this becomes a ſymptom in hyſteric complaints.

The *iſchury* principally attacks young men, and moſtly thoſe of plethoric habits; and thoſe who have been too free with hot medicines, ſtrong liquors, and powerful diuretics.

Causes. The cause of a *strangury* is a spasmodic contraction of the sphincter, and neck of the bladder, attempting to throw off something that is troublesome; and the fermentative state of the urine, accused by many as the cause of this disease, has indeed no share in the occasioning it. The *dysury* sometimes has its cause and origin in the kidneys, sometimes in the bladder, and when in the last place, a spasmodic constriction of the sphincter is often the case, and this is not unfrequently brought on by a high diet, the feeding on very salt foods, or using too much spices. The *ischury* is often occasioned by accidents; such as a stone, gravel, a worm, a grume of blood, or a collection of purulent matter stopping up the passage in the neck of the bladder; sometimes it is occasioned by a venereal caruncle, or inflammatory tumor; sometimes by the weight of the uterus in women with child, when near the time of their delivery; sometimes by external violence; and sometimes by the sitting a long time drinking, without going to make water; but this last more rarely happens. *Junker's* Consp. Med. p. 533.

Prognostics in these cases. A simple and idiopathic *strangury* is rather a painful, than a dangerous disease; but if it often recurs upon the person, it bespeaks a calculous nephritic complaint for its cause: and, in general, it is a worse complaint in old people, than in the young or middle aged. The *dysury* is of the same nature with the *strangury* in its event, but the longer it continues, the greater danger there is of its bringing on spasms and fevers. But though these two cases are not attended with any very imminent danger, the *ischury* is, especially when it is of some days standing; for if it is not cured before the seventh day, an inflammatory fever comes on, which is usually followed by a speedy mortification, and by the death of the patient with hiccups and violent convulsions. People subject to *ischuries* are also in danger of dropsies; and dropsical people are more subject to this complaint than any others, especially when the disease is increased to a considerable height.

Method of cure. The *strangury* and *dysury* are to be treated in the same manner. The acrimony of the fermentitious matter in the blood, which might be apt to occasion new congestions, is to be obtunded, and the spastic motions taken off: both these purposes are excellently answered by nitre, whether given alone, or mixed with some abstersive salt, or with an absorbent, mixed with a small quantity of an acid to saturate it, and with a little cinnabar. A compound powder may be prepared of these ingredients, and a scruple of it given four times a day, will usually soon take off the complaint. The cooling emulsions, made with barley-water and almonds, and with the cold seeds, are also of great service; and when there is farther occasion for medicines, gum arabic, and pills of boiled turpentine, are found very good ones; and decoctions of liquorice-root in barley-water, with syrup of marsh mallows, may be drank in large draughts. Many people are also fond of external remedies, and recommend onions, roasted and buttered, to be applied to the pubes, and goat's suet to be rubbed warm about the navel.

In cases of the *ischury* there is occasion for greater medicines, and the method must necessarily be varied, according to the state of the patient, and the cause of the disease. The first thing to be done, is the injecting an emollient clyster to loosen the bowels, for when these are emptied, the other complaint will be much more easily removed: after the clyster, powders composed of cinnabar, nitre, and diaphoretic antimony, are to be given, to prevent an inflammation in the abdomen, and to attemperate the offending matter. When these things are done, the peculiar causes of the disease are to be examined. If a plethora and violent emotion of the blood be in fault, making a congestion of it at the kidneys; in this case, if the beforementioned methods do not take effect, bleeding in the foot will be of service, and an external use of camphorated ointments probably will compleat the cure. When the cause is a spastic constriction of the ureters and kidneys, then the relaxing medicines are to be given, and gentle purges of senna, manna, and the like, will be of great use. Externally warm baths, oily liniments and ointments, and emollient cataplasms, are also great assistants to the internal medicines.

If a small stone, or a grume of blood, or mucous matter, or a worm, have stopped up the passage, and prevented the urine from passing after the clyster, and the powders are found not to have the desired effect, the catheter is to be introduced; or if the stone be lodged in the urethra, the injecting a little oil may be of use to lubricate the passage, and ease its way out. When a genuine nephritis is in the cause, this is first of all to be regarded, and treated in the common way. See NEPHRITIS.

If a venereal caruncle be in the way, it must be taken down by the surgeon with the septics usually employed on those occasions; and if the case be violent, and of this kind, the cure must be perfected, by treating the patient in the usual method in venereal cases.

If an inflammatory tumor stops the neck of the bladder, this is to be discussed by resolvents internally taken, and externally applied to the pubes; and if there is an erosion, or ulceration, balsamics are to be given, and particularly the pills of boiled turpentine. *Ischuries* in infants are cured by giving crabs eyes, and the like powders, with the usual catarrhal medicines to the nurse who gives them suck. Finally, in cases of grown people, as soon as the urine comes away at all, the common diuretics are to be given, as the daucus seeds, and the like, with gentle purges at the intermediate times; but it is a very dangerous practice to give diuretics, before the cause of the obstruction is removed, and since they always add greatly to the pain and misery of the patient.

There is no medicine so useful in these cases as nitre, and it is better given in substance than any other way; for its dulcified spirit, though well known as a diuretic, is less safe than the salt itself. Many people have a great opinion of specifics in these cases, and golden-rod, and mouse-ear, and ground ivy, are accounted of that number, as also violet seeds, and powder of egg-shells; but it is a very dangerous thing, in cases of so great importance, to rely upon uncertain remedies. A common *strangury* often is carried off by mere diluters, such as tea, barley-water, or any other watery liquor, drank in large quantities till a sweat comes on; and in the gentler cases, where these alone are not quite effectual, there is no better addition to them than a little nitre. Bleeding in time often prevents great mischiefs from these disorders; and in cases of a *dysury*, brought on by the taking cantharides, there is no remedy so powerful as warm milk alone, drank in large quantities. The great Mr. Boyle has also said much in the favour of Venice soap on this occasion. *Junker's* Consp. Med. p. 534, 535.

STRAP (*Cycl.*)—STRAP, in a ship, the rope which is spliced about any block, and made with an eye to fasten it any where on occasion.

STRAPS, in the manege. The *straps* of a saddle are small leather *straps*, nailed to the bows of the saddle, with which we make the girths fast to the saddle.

STRAPAZINO, in zoology, the name of a bird of the wheat-ear kind with a white rump and tail, and of a brownish yellow on the head and back. Its wings are variegated with black and yellow, and its beak is longer, and of a brownish colour. Its throat, breast and belly, of a yellowish white. It is common in Italy, and is frequently brought to market among the small birds. *Bellonius*, de Avibus.

STRASITES, STASITES, or STAXITES, a stone described by the writers of the middle ages, and famed for its imaginary virtue of promoting venery, assisting digestion, and the like, and that whether taken inwardly, or outwardly applied. It is not easy, from the accounts they have left us, to guess what stone they mean.

STRATA, (*Cycl.*) the beds of different kinds of matter, of which the crust of the earth is composed.

The most frequent opportunities we have of observing these in England, is in the coal mines in coal countries. Here we find them lying in a regular manner, on what appears to us a plane, as we see any small part of it; but when we consider the same *strata*, according to the globular figure of the earth, and suppose the mass of the earth to consist of the foregoing, and perhaps in different parts, and at different depths of *strata*, of ten thousand other kinds, all originally, while in a soft and fluid state, tending toward the center, we shall find that it must mechanically, and almost necessarily follow, by the continual revolution of the crude mass from west to east, like the winding up of a jack, or the rolling up of the leaves of a paper-book, that every one of these *strata*, though they each reach the center, must, in some place or other, appear to the day, or on the surface. In which case, there needs no specific gravitation to cause the lightest to be uppermost; and were it practicable to sink to the center of the earth, all the *strata* that are would be found in every part, and, according to the poet, *ponderibus librata suis*. Add to this, that, according to an observation of Dr. Stukely, the precipices of all hills are to the westward, whereas the ascent to the east is more gradual. Philos. Trans. N° 391. p. 396.

STRATEGUS (*Cycl.*)—Towards the declension of the Roman greatness, the chief magistrate of Athens was called by the name of Στρατηγος, *dux*. Constantine the great, besides many other privileges granted to that city, honoured him with the title of Μεγας Στρατηγος, *magnus dux*. *Potter*, Archæol. Græc. lib. I. cap. 7.

STRATOR, among the Romans, an officer who took care of the horses, furnished by the provincials for the public service. *Pitisc.* in voc.

STRATOR is also used for an officer in the army, whose business it was to take care there was nothing in the roads to hinder or incommode the army in its march. For which purpose he ordered banks and steep eminences to be levelled; laid bridges, cut down woods, and assisted the quarter-master to find out places proper for transporting the army over rivers. *Pitisc.* in voc.

STRATOR is also used for an equerry, who held the bridle of the prince's horse, and assisted him in mounting. This officer was by the Greeks called *anaboleus*. *Pitisc.* in voc. See the article ANABOLEUS.

STRATOR likewife denotes a furveyor of the high-ways. *Pitifc.* loc. cit.

STRAWBERRY, *fragaria*, in botany. See FRAGARIA.

The common *ftrawberry* is frequent in the woods of England, and is thence tranfplanted into gardens. The beft feafon for this is in September, that the plants may be rooted before the frofts. They may alfo be tranfplanted in February; but then, if the fpring fhould prove dry, they will require a great deal of watering to keep them alive.

The proper foil for *ftrawberries* is a light hazely loam, not over rich; the ground muft be well dug, and very carefully cleared of all noxious weeds; and when it is levelled even, it fhould be marked out into beds about three feet and a half wide, leaving a pathway between each bed of two feet broad. In each of thefe beds fhould be planted four rows of plants, fo that they may ftand about a foot diftant from each other in the rows, and they fhould be planted at about eight inches plant from plant in each. This is the proper diftance for the wood *ftrawberry*, which is of the leaft growth of any; but the fcarlet *ftrawberry* muft be planted at a foot diftance every way, and the heautboy fixteen inches; and finally, the large Chili *ftrawberry*, which is the largeft grower of all, muft be fet at twenty two inches diftance plant from plant.

In the fpring, when the *ftrawberries* begin to flower, if the feafon is dry, they muft be very plentifully watered, and they muft be kept very carefully cleared from weeds. At Michaelmas the beds fhould be dreffed, the weeds all very carefully taken up, all the ftrings or runners muft be taken from the roots, and the weak plants, which ftand too clofe, muft be pulled up; throwing a little fine earth, at the fame time, over the plants, alfo greatly ftrengthens their roots. Thefe beds, however well managed, will not continue good above three years; and the beds of the firft year bearing but few fruit, it is neceffary to new-plant fome frefh ground every third year, and deftroy the old beds; but the new ones muft be firft of one year's growth.

Different palates prefer different fpecies of *ftrawberry*, but the white-fruited one is, of all others, the beft flavoured; though it is but a very bad bearer. The great Chili *ftrawberry* is cultivated in the fields in that country; it is a much ftronger and larger plant than any of our kinds, and its fruit is as large as a wallnut, but not fo well tafted as our own *ftrawberries*. Mr. Frezier brought them fome years ago to Paris, and fince that they have been fpread over the feveral parts of Europe. They grow beft in a loamy foil, under the fhade of trees. *Miller's* Gard. Dict.

STRAWBERRY-*tree*. See the article ARBUTUS.

STREAK-*fallowing*, in hufbandry, a particular fort of tillage. The way of doing it, is to plow one furrow, and leave one, fo that but half the land is plowed, each furrow that is fo lying on that which is not: when this is ftirred, it is then clean plowed, and laid fo fmooth, that it will come, at fowing time, to be as plain as before. This is done, when lean and poor lands are not fwardy enough to bear clean tillage, nor light enough to lie to get fward. The intent of this tillage is to keep the fun from fcorching them too much; but in many places they think this wears their land too faft, and therefore are not fond of having recourfe to it. *Plot's* Oxfordfh. p. 248.

STREAMERS, in a fhip, the fame with *pendants*. See the article PENDANT, *Cycl.*

STRENGTH (*Cycl.*)—STRENGTH *of fpirits*, among diftillers, that quality by which they become inflammable, and which they have in greater or leffer proportion, as they are more or lefs debafed by an addition of water.

Dr. Shaw has very well recommended to the world the method of felling and buying fpirits in their moft highly-rectified ftate, that is, when they are totally inflammable. By this means, as the burning a fpoonful of the goods would always be a proof of their quality, there could be no room for thofe cheats, which are now too common between the feller and buyer. As this, however, is not likely to be brought into practice, it may be of great ufe to thofe, who traffic in fpirits, to have fome more certain way of judging of their *ftrength* than that by the bubble proof, or crown of fpume arifing on fhaking; which being wholly owing to a mixture of the effential oil of the ingredient from which the fpirit is made, with the fpirit, may be fophifticated by the addition of other oils, or faponaceous fubftances, or by any thing that can give a greater vifcofity to the fpirit than it had before.

The fureft method of judging of the *ftrength of fpirits* is by the hygrometer, water-poife, or balance; or 2. by diftillation; or finally, by deflagration. The fpecific gravity of totally inflammable fpirit is fo much lefs than that of phlegm, or common water, that it is eafily fenfible upon the balance; whence an exact hygrometer, well balanced and graduated, and furnifhed with a proper fcale and weights, may be of great ufe to affign the proportions in which pure fpirit and water are mixed in any given liquor. Though perhaps a readier way than this may be that of Mr. Homberg's, mentioned in the Memoirs of the Paris Academy 1718, for determining the different gravities of different fluids, by means of a bottle with a very long and flender neck; which being filled to a certain height with any mixture of fpirit, is weighed againft the fame bottle filled with pure water.

The moft exact, of all methods of determining the *ftrength* of any fpirit, is by diftillation, rectifying it up to an alcohol, or totally inflammable fpirit; but this, though liable to no error, is too tedious to come into common ufe. And, upon the whole, the beft method, of all others, feems to be that of deflagration, which Mr. Geoffroy has been at much pains to adjuft and improve. *Shaw's* Effay on Diftillery. See the article SPIRITS.

STRENGTHNERS (*Cycl.*)—An artificial method of procuring a powerful, fafe, and innocent *ftrengthner*, is the following. Put half a pound of fine Peruvian bark, reduced to a fubtile powder, into a long or tall glafs body, and pour upon it two quarts of fpirit of wine; fhake them well together, and fet them in a fand-heat two or three days, or till the fpirit of wine is of a fine purple colour; pour off this tincture, and prefs the fæces very ftrongly, to get it all away; then return the powder into the fame veffel, and pour upon it two quarts of ftrong white wine; fet this in fand for two or three days, then pour off this tincture; mix it with the former, and putting the whole into a glafs body, diftill off a great part of the fpirit of wine; then put the remainder into a glazed earthen pan, and evaporate it to the form of an extract, adding, toward the end, three ounces of fyrup of orange peel.

This is the invention of Charas, and feems the beft preparation of bark known. Befide all the common cafes in which the bark is given, this preparation may be tried in other weakening diftempers, as well as intermitting fevers, as the inconveniencies attending the taking the bark in fubftance are obviated by this preparation, which is equally powerful and innocent. It may be aromatized at pleafure with any of the effential oils. *Shaw's* Lectures, p. 232.

STREPITOSUS, the name of a diftemper common to the inhabitants of fome parts of the Alps, in which the face, neck and arms, are fo diftended with flatulencies, as to make a noife, when ftruck, like a dry bladder half diftended with wind.

STREPSICHEROS *ovis*, in natural hiftory, the name of a fpecies of fheep defcribed by Bellonius, and found in the ifland of Crete in great flocks. They are of the fize of our common fheep, but their horns are erect, and twirled into a fpiral line, and beautifully furrowed on their outfide. *Bellon.* Obferv. lib. 1. cap. 14.

STRETTO, in the Italian mufic, is fometimes ufed to fignify that the meafure is to be fhort and concife, and confequently quick. In this fenfe it ftands oppofed to *largo*. See the article LARGO.

STRETWARD, in our old writers, an officer whofe bufinefs it was to take care of the ftreets, like our furveyor of the high-ways, or rather fcavenger. *Blount.*

STREVER, in zoology, a name given by many to the fifh called by authors *afper pifciculus*.

It in fome degree refembles in figure the *lucioperca*, or pikepearch, but is more flender than that fifh toward the tail. Its back has a hollow on its anterior part near the head, and its fides are marked with feveral obliquely tranfverfe lines, like thofe of the pearch. Its back is fcaly, its breaft braked. It has two back fins, a fhort and prickly one before, and a longer behind; and the bony coverings of its gills terminate each in a fharp fpine. *Gefner*, de Aquat. p. 478.

Gefner, in particular, calls this fifh *gobius afper*. It is a genuine fpecies of pearch, and is diftinguifhed by Artedi by the name of the *pearch* variegated with eight or nine tranfverfe black lines on a fide.

STRIATA *corpora*, a term ufed by anatomifts to exprefs two protuberances of the brain, upon the crura of the medulla oblonga. See CEREBRUM.

STRIATED *leaf*, among botanifts. See LEAF.

STRIATED *ftalk*. See the article STALK.

STRIATULA, in natural hiftory, a name given by Mr. Lhuyd to a fpecies of foffile plants of the fern kind, remarkable for their *ftriated* appearance. See the article *Foffile* PLANTS

STRIBILIGO, a name given by fome authors to any fort of cutaneous efflorefcence.

STRIGA, among the Romans, a fpace or interval in a camp, 120 feet long, and 60 feet broad, ufed for currying and rubbing down the horfes. *Pitifc.* in voc.

STRIGA is alfo ufed for a furrow drawn out at length, for a long row, or feries of any thing, and by furveyors for a long meafure. *Pitifc.* in voc.

STRIGIL, an inftrument ufed among the antients in their baths, and at fome of their gymnaftic exercifes.

It ferved to abfterge the fweat, or other fordes from the body. Perfons who intended to bathe, or to ufe any of thefe exercifes, when they entered the gymnafium, put off their clothes in the apodyterium; after which, fuch of them as intended to box, wreftle, or ufe any of the more violent exercifes, went into the alipterium, where they were anointed, and thence returning into the place where the duft was, they were fprinkled with this as they paffed along, and then entred

entred upon their feveral exercifes; after this they returned to the alipterium, where they had the fweat and fordes wiped off from their bodies by the alipta with an iron *ftrigil.*

The fordes taken off from the body, and confifting of oil, duft, and fweat, were preferved for medicinal purpofes, and we find them ufed among the old phyficians.

The *ftrigils* were of the fhape of a gardner's knife; they were made of different materials, as ivory, horn, gold, filver, iron, brafs, and the like; but in fome after times the word was only ufed to fignify a linnen cloth, or a piece of fpunge, which every one carried about him for his own ufe. The fordes, faved for medicinal purpofes, were called *ftrigmenta.* See the next article.

STRIGMENTUM, the filth, dirt, or fordes, abfterged from the fkins of thofe that bathed in the baths and places of public exercife among the antients, or from the walls of bathing places, or ftatues fet up in them.

Thefe were all referved for medicinal purpofes, and were properly of three kinds. The firft, or bath *ftrigments*, confifted of the fweat, oil and fordes, collected in thofe places. The fecond kind was the *ftrigments* of the palæftra, confifting of the fame things, with the addition of duft, which was thrown upon the bodies of the perfons before they entred on thofe exercifes. The third kind was that collected from the walls of the gymnafia, and from the ftatues, of whatever materials they were made, which were placed there. Hence the nature of the firft and fecond kind might always be afcertained, but that of the third was very different; for as it was often collected from brafs and copper ftatues, it partook of the nature of the ruft, or ærugo of thofe metals which was collected from them with it.

Thefe *ftrigments* were fuppofed to be of a heating, drying quality, and difcutient; they were, therefore, ufed for difcuffing the parotides, and for condylomata of the anus. Thofe of the palæftræ were ufed to difcufs collections of matter about the joints; and applied in the manner of a cataplafm, were faid to be of great ufe in the fciatica: and thofe collected from the walls and ftatues were ufed to cleanfe old ulcers.

STRIGONIENSIS *terra*, earth of *Strigonium*, in the materia medica, a red earth of the bole kind, found about the gold mines at *Strigonium* in Hungary, and ufed in fome places as an aftringent and fudorific.

The characters by which it is known from the other earths, are thefe. It is but of a coarfe and impure texture, and lighter than moft of the boles; in colour it is of a ftrong, but dull red, and is of a tolerably fmooth furface. It is apt to crumble to pieces between the fingers, and ftains the fkin in handling. It melts freely in the mouth, and has a remarkable fmoothnefs, but very little aftringency in its tafte, and leaves a fenfible grittynefs between the teeth. It is fometimes veined and fpotted with fmall moleculæ of an earth, like the whitifh variegations of the red French bole. It makes a flight effervefcence with aqua fortis, or any other acid menftruum, and fuffers no change of colour by burning. *Hill*'s Hift. of Foff. p. 11.

STRIGOSULA, in natural hiftory, a name given by Mr. Lhuyd to a fpecies of foffile oifter-fhell. See the article *Foffile* SHELLS.

STRIKE (*Cycl.*)—STRIKE *a nail*, in the manege, is to drive through the horfe's fhoe, and the horn or hoof of his foot, and to rivet it for holding on the fhoe.

STRIKE *a vein*, in the manege. See BAR, *Append.*

STRIKING (*Cycl.*)—STRIKING-*wheel*, in a clock, the fame with that which by fome is called the *pin-wheel*, becaufe of the pins which are placed on the round or rim (which in number are the quotient of the pinion divided by the pinion of the detent-wheel.) In fixteen days clocks, the firft, or great wheel, is ufually the pin-wheel; but in fuch as go eight days, the fecond wheel is the pin-wheel, or *ftriking-wheel.* See PIN-*wheel*, *Cycl.*

STRILLOZZO, in zoology, a name by which fome authors have called the emberiza alba, or bunting, or perhaps a bird fomewhat different from our bunting, and common in Italy: for it is not yet afcertained, whether the *ftrillozzo* fpecifically differs from the bunting, or only by fome accidental variegations.

STRING (*Cycl.*)—STRINGS *of metal*, a term ufed by our miners to exprefs thofe thin and fmall veins of ore, into which the beds or veins degenerate toward their terminations. Thefe are from an inch to a tenth part of that in thicknefs, and run through the folid rocks to a great diftance. The ore in them is ufually very pure and rich, and as they lie in the rocks, communicating with the larger veins of ore, they refemble the feveral fmall brooks and rivulets in a hilly country, which by degrees uniting all their ftreams, form the rivers. See the articles LOAD and VEIN.

STRINSIA, in ichthyology, a name given by authors to that fpecies of the gadus, which is called by fome *lota*, and by others *muftela fluviatilis*; by us in Englifh the *eel-pout.* Olaus Magnus calls it the *borbocha*; and Artedi, who refers it to the genus of the gadi, diftinguifhes it by the name of the *gadus* with two fins on the back; with even jaws, and beards at the mouth. See the article GADUS.

STRIP, at fea. A chafe is faid to *ftrip* himfelf into fhort or fighting fails, when he puts out his colours in the poop; his flag on the main-top; his ftreamers or pendants at the end of his yard-arm; furls his fprit-fail; peeks his mifen; and flings his main-yard. In which cafe the chafer muft prepare himfelf for fight.

STRIVALE, in zoology, the name ufed by many for the fifh more ufually known by the name of *aper*, the boar-fifh. It is a fmall fifh, of the fhape of the doree, caught in the Mediterranean. *Aldrovand.* de Pifc. p. 270. See Tab. of Fifhes, N° 19. See the article APER.

STRIX, the *owl.* In the Linnæan fyftem of zoology, this makes a diftinct genus of birds of the hawk kind, the diftinguifhing characters of which are, that the feet have three toes before, and only one behind, none of which are moveable backwards. *Linnæi* Syft. Nat. p. 44.

STRIX is more particularly made the name of the common *brown owl*, or *ivy owl.* This is diftinguifhed from the other fpecies of the *owl* kind by thefe characters.

Its beak is of a pale horn colour, and but fhort, yet the opening of its mouth is very wide. Its eyes are remarkably large and protuberant, and the apertures of its ears very large; and covered with a membrane; and its eyes are nearer to its ears, than in any other animal. Its face is furrounded with a double circle of feathers, and its back is mottled with brown and black, and its belly of the fame colour, but fomething paler, as if it had a mixture of whitifhnefs. The legs are feathered almoft down to the toes, and the outer feather of its wing is much fhorter than the reft, by which it is diftinguifhed from the aluco without any farther mark. *Ray*'s Ornitholog. p. 66.

STROBILE, a word ufed by chirurgical writers to exprefs a pledget of a twifted form.

STROBILUS, among botanifts, a kind of pericarpium, formed of a number of vaginæ with contorted points applied clofe to one another. See PERICARPIUM.

STROBULUS, among the antients, a kind of mitre, which rofe to a height by many windings and turnings, and ufed by the barbarians; inftead of which the Romans wore the *apex*, which had a high, but ftreight top. *Pitifc.* in voc. See the article APEX.

STROCAL, in glafs making, a long iron Inftrument like a fire-fhovel, ufed to empty the metal out of a broken pot into a whole one. *Neri*'s Art of Glafs Append.

STROMATEUS, in ichthyology, a genus of fifhes of the malacopterygious, or foft-finned kind, the characters of which are thefe. The body is very much compreffed, and very broad and thin; it has no belly fins, and has only one back fin, which is extended over the whole back. The only known fpecies of this genus is the *callichthys* of authors, a fifh called the *fiatola* at Rome. The tail is very forked; the mouth is very fmall; the teeth are placed in the jaws and palate; and the tongue is fmooth and broad. The body is ftriped crofsways. *Artedi*, Gen. Pifc. p. 15.

The *ftromateus* is a broad, flat, and fhort fea-fifh, fomething refembling the turbot in figure, and thin both on the back and belly, but fwimming erect, not flatwife.

Its common fize is of about a pound and half weight; its colour on the back a pale bluifh, and on the fides and belly a filvery white; and on its back, and upper part of its fides, it is very beautifully variegated with yellow lines and fpots, and towards its belly with others of a paler tinge of the fame colour. There are two longitudinal lines on the fides, the one ftrait, the other arched and bent. Its fkin is extremely thin and tender, and is covered with fcales. The tail is forked, the end of the fnout obtufe, and the mouth very fmall. It has only one row of teeth in each jaw, but it has, befide thefe, two bony fubftances in its mouth, all over covered with fmall teeth. It has no belly fins, but has two fmall ones at the gills, and one long one running down the back, and another fingle long one anfwering it near the tail. It is caught in the Mediterranean, and brought to market at Rome under the name of the *lampuga*, and is a very delicate fifh. *Ray*'s Ichthyography, p. 156.

STROMBUS, in conchyliology, the name of a genus of fhells, nearly allied to the buccinums, and called by the generality of authors *turbo.* See the article TURBO.

STROMLINGUS, in ichthyology, a name given by fome writers to the *aras* of the Greeks, which is no other than the common herring. See the article HALEC.

There is no other difference between the *ftromling* and herring, but that the former is fmaller.

STROPHIARIUS, among the Romans, a perfon who prepared and made the *ftrophia.* See STROPHIUM.

STROPHIUM, among the Romans, a fhort fwath or band, wherewith the young women kept down the fwelling of their breafts. *Pitifc.* Lex. Ant. in voc.

STROPHIUM was likewife a bandage for the head, made of two or three garlands of flowers tied together. *Pitifc.* loc. cit.

STROPPUS, among the Romans, the thong with which the oars were tied to the *ſcalmus*. *Pitiſc.* Lex. Ant. in voc. See the article SCALMUS.

STRUFERTARII, among the Romans, perſons hired to perform ſome kind of ſacrifices near the trees that had been thunder-ſtruck. *Pitiſc.* in voc.

STRUMARIA, a name by which Galen has called the little burdock. *Ger.* Emac. Ind. 2.

STRUMUS, in botany, a name given by ſome of the old Roman authors to the *cucubalus*, or berry-bearing chick-weed.

It had this name from its being found of ſervice in *ſtrumous* and ſcrophulous ſwellings, when externally applied. The name *cucubalus* ſeems to have been derived from the word *halicacabum*, or the winter cherry, for the antients eſteemed both theſe plants ſpecies of nightſhade; and ſome of them have plainly deſcribed the *cucubalus* under the name of *ſolanum hortenſe*.

STRUPPI, among the Romans, garlands or wreaths of vervain, wherewith the ſtatues of the Gods were crowned. *Pitiſc.* in voc.

STRUT, a term uſed by ſome builders for that brace which is framed into the king-piece and the principal rafters. See BRACE, *Cycl.*

STRUTHIO, in zoology, the name of the oſtrich in the Linnæan ſyſtem. Others uſually call it the *ſtruthio camelus*. According to the ſyſtem of that author, this makes a diſtinct genus of birds, the characters of which are, that it has only two fore toes on each foot, and no hinder ones. See Tab. of Birds, N° 19. *Linnæi* Syſt. Nat. p. 47.

STRUTHIOMELA, a word uſed by Pliny and the antients to expreſs a ſort of quinces, which were ſmaller than the common kind, and of a ſweeter juice and leſs aſtringent.

STRUTHIOPTERI, in natural hiſtory, a name given to a ſeries of flies, of the claſs of thoſe which do not feed on fleſh: theſe have remarkable ſhort wings, and are always found on flowers and leaves of plants. There are ſeveral ſpecies of theſe. The moſt frequent among us are a white-bodied one with black wings, which cover but a very ſmall part of the back, and with feathered wings; and two others with long bodies, of a duſky grey, ſtreaked with white. Theſe are all early flies, being found in the ſpring in hedges and buſhes.

STRUTHIOPTERIS, in botany, a name by which Tragus, and ſome other authors, have called the *lonchitis*, or ſpleenwort. *Ger.* Emac. Ind. 2.

STRUTHIUM, in natural hiſtory, a name given by the Greeks to a plant called by the Latins *lanaria herba*, from its uſe in the manufacture of their wool. Many have ſuppoſed the *chaſcuſa* of the antients to be the ſame with this plant, but that is an error, for the *chaſcuſa* of the Greeks is the *antirrhinum* of the Latins, as is plain from Pliny; and the ſame author tells us, that it has leaves like thoſe of flax, ſmall, narrow, and ſmooth. All the account we have of the *ſtruthium* is from Dioſcorides, who ſays, that it was a kind of thiſtle, ſomewhat reſembling the ſcolymus, and having a large root, long, and of the thickneſs of two or three fingers, and very ſharp prickles on the leaves. This ſhort account, though not enough perhaps certainly to inform us what the plant was, is yet abundantly ſufficient to prove, that it was not the chaſcuſa, or antirrhinum.

Many have ſuppoſed that the *candes*, or *candiſi* of the Arabian writers, is the ſame plant with the *ſtruthium* of the Greeks, and the old interpreters of the works of Avicenna and Serapion tell us that it is ſo; nay, Avicenna himſelf gives us the deſcription of the *ſtruthium*, as it ſtands in Dioſcorides, under his name *candiſi*, and Serapio under his title of *candes*: but all that we may learn from this, is, that the Arabians were as liable to errors about the Greek Phyſicians works as ourſelves, and that the *ſtruthium* of the antients was as much unknown in their days as in ours. Alphagus gives us a genuine deſcription of the candes, or candiſi, out of the writings of Ebenbita *de Simplicibus*, who ſays, that it was common in Syria; and expreſly adds, that neither Dioſcorides, nor Galen, were at all acquainted with it, nor had any where mentioned it under any name.

It may ſeem ſtrange to ſome, that Serapio and Avicenna ſhould miſtake the plants of Dioſcorides, and their other Greek predeceſſors; but we find, by Avicenna's character of the artanita, which is not the *artanita*, but the *leontopetalon* of Dioſcorides, that the Greek phyſicians works were at that time tranſlated into the Arabic language; and theſe Arabians uſed that tranſlation in their own tongue, never troubling themſelves to refer to the original. Now though it is probable, that neither Serapio nor Avicenna would have erred about the plants of Dioſcorides, had they read the works of that author in the original, yet is very eaſy to ſuppoſe that a common tranſlator might make blunders about ſuch nice ſubjects as the ſynonyms of plants; and theſe muſt all be tranſplanted into the works of the Arabian writers, who, according to their own accounts, made uſe of theſe tranſlations, inſtead of the originals; and on this foundation we may ſafely affirm, that the *artanita* of the Arabians is the *leontopetalon*, not the *artanita* of the modern times, and that the *candes*, or *candiſi* of the Arabians, though we do not know what it is, yet evidently is not the *ſtruthium* of the Greeks.

We find the *ſtruthium* celebrated among the Romans for its virtues; but all the account we have of it from them, is, that it was a prickly plant, and was very common in the Grecian iſlands. This however is ſufficient to convince us of the great error of thoſe who make this plant, and the *oſtrucium* of the later writers, to be the ſame plant. The oſtrucium is the Smyrnium, or Alexanders, and can by no means be ſuppoſed the ſame with this prickly plant; yet Macer has made them the ſame, and has attributed to the Smyrnium, or Alexanders, the virtues which Theophraſtus gives to the ſtruthion.

STRUTHIUM, in the materia medica, is uſed by modern authors as the name of the *luteola*, or dyers weed, a common wild plant with narrow leaves and yellow flowers. *Dale's* Pharm. p. 248.

STRUTHIUM is alſo uſed by ſome for the *ſaponaria*, or ſoapwort. *Ger.* Emac. Ind. 2.

STRYCHNUS, a name given by the antients to the plant we call *ſolanum*, or nightſhade. Some of the old authors have alſo called this *tithymal*; and in the times of Theophraſtus, we find that tithymal and nightſhade were ſynonymous terms.

The oldeſt authors [b] mention only three kinds of *ſtrychnus*, or nightſhade; the one they call the *ſleepy nightſhade*, the other the *mad nightſhade*; theſe two being poiſonous, and exerting their bad effects, by making people ſleepy or mad; and the third they called the *eſculent nightſhade*. This ſeems to have been the ſame with our *pomum amoris*, or love apples; which, though not much eſteemed in England, yet in Spain, and many other parts of the world, are univerſally eaten in ſoups, &c.—[b *Theophraſtus*, lib. 9. cap. 11.]

Pliny [c], in his account of the ſolanum, ſeems to intend the ſame thing as Theophraſtus; but having collected the accounts of different authors, and put them together in a confuſed manner, it is not eaſy to comprehend what he means; and to add to the perplexity, this is one of the parts of that author where the copies are very faulty.—[c Lib. 21. cap. 31.]

STUB, in the manege, is uſed for a ſplinter of freſh-cut under-wood, that goes into a horſe's foot as he runs; and piercing the ſole through to the quick, becomes more or leſs dangerous, according as it ſinks more or leſs into the foot.

STUD, in the manege. See BREED.

STUDDING-*ſail*, in a ſhip, the ſame with what is called a *gooſe-wing*. See the article GOOSE-*wing*.

Studding-ſails, are bolts of canvas, or any cloth that will hold wind, extended in a fair gale of wind along the ſide of the main-ſail, and boomed out with a boom. They are ſometimes alſo uſed to the clew of the main-ſail, fore-ſail, and ſprit-ſail, when the ſhip goes either before the wind, or quartering.

STUFFING, or CONGESTION, in medicine, the name of a diſtempered ſtate of the body, in which there is a ſpecial and peculiar direction of the blood, in larger quantities than ordinary, to ſome particular places, in order to its there making its way out by an hæmorrhage, and relieving nature from an over-abundant quantity of it, that the reſt may circulate the more freely and eaſily.

Congeſtions differ in regard to the places where they appear; ſome are made in the head, others in the breaſt; ſome in the hypocondria, and ſome in the kidneys; and others in the hæmorrhoidal veſſels. In this alſo there is ſome regularity in regard to the age and conſtitution of the patient; for in young perſons *congeſtions* are uſually made in the head, in middle-aged people in the breaſt, and in thoſe ſomewhat farther advanced in years toward the abdomen.

Medical writers diſtinguiſh *congeſtions* into two kinds, the *complete*, and the *incomplete*. The complete *congeſtions*, are thoſe in which the blood is directed to ſuch a part where it is natural and eaſy for it to be diſcharged by an hæmorrhage; ſuch are the head, the lungs, the uterus, and inteſtinum rectum; and in which it is carried in large quantities to the very parts.

The incomplete *congeſtions*, are thoſe in which the blood is indeed directed toward theſe, or the like parts, from whence it ought to be diſcharged, but never is carried to them, or indeed near them, but collecting itſelf at a diſtance from them, can never come to a diſcharge by a hæmorrhage. Something of this kind is obſerved in the rheumatiſm, gout, and what are called the *cold catarrhs*.
